Preface and Acknowledgment

The 2011 Population and Housing Census of Albania is the 11th census performed in the history of Albania. The preparation and implementation of this commitment required a significant amount of financial and human resources. For this INSTAT has benefitted by the support of the Albanian government, the European Union and international donors. The methodology was based on the EUROSTAT and UN recommendations for the 2010 Population and Housing Censuses, taking into consideration the specific needs of data users of Albania.

In close cooperation with international donors, INSTAT has initiated a deeper analysis process in the census data, comparing them with other administrative indicators or indicators from different surveys. The deepened analysis of Population and Housing Census 2011 will serve in the future to better understand and interpret correctly the Albanian society features. The information collected by census is multidimensional and the analyses express several novelties like: Albanian labour market and its structure, emigration dynamics, administrative division typology, population projections and the characteristics of housing and dwelling conditions.

The series of these publications presents a new reflection on the situation of the Albanian society, helping to understand the way to invest in the infrastructure, how to help local authorities through urbanization phenomena, taking in account the pace of population growth in the future, or how to address employment market policies etc.

The five editions of this series are in-depth analysis conducted by INSTAT in collaboration with the University of Geneva, University of Neuchâtel and Urban Research Institute, and supported financially by the SDC - Swiss Agency for Development and Cooperation.

INSTAT avails itself of this opportunity to express its gratitude and acknowledgement for the valuable contribution of the SDC - Swiss Agency for Development and Cooperation, INSTAT experts and other local and international experts for the publication of the series of analyzes of population and housing census 2011

Special appreciation also goes out to all institutions and donors, who have contributed to the conduction of the population and housing census 2011, the Albanian Government, European Union (IPA 2009 and CARDS 2006), SIDA – Swedish Agency for International Development, SDC - Swiss Agency for Development and Cooperation, UNFPA – UN Population Fund, and UNDP – United Nations Development Program.

Introduction

Population projections inform on the future number, demographic structure and territorial distribution of inhabitants under the most plausible assumptions of trends in demographic behaviour. They are of interest for the society at large as a basis for planning of social and economic development and market research. This report presents the results of the third round of population projections of INSTAT. The first round was based on the 1989 Census and realised at the national level for a horizon of 21 years (regional populations were estimated for five years). These projections have been updated based on the 2001 Census and extended to the year 2021, for the country and its main regions (INSTAT 2004b). At that time, Albanians engaged in large-scale internal and international movements (thereafter called out- or in-migration and emigration or immigration, respectively), and residents strongly reduced their number of births.

These demographic trends continued in the 2000s. International migration was sustained and diffused throughout the country, leading to a continued decline of the population of Albania, especially in border areas. This was sustained by internal movements in increasing the concentration of residents in urban areas – most notably in Tirana. All prefectures also recently engaged in a trend towards low fertility, which does not ensure anymore the demographic reproduction of populations in the future. The combined effects of low fertility and the large scale departures of mainly young adults accelerated the pace of population ageing. This third round of population projections aims to inform on the most plausible trends in these demographic challenges of Albania in the future and estimates the consequences on the national and prefectural populations by age and sex through 2031, based on the last Population Census in 2011.

The difficulty of forecasting in such a dynamic demographic context is evinced by the previous projections rounds' over-projection of total population for 2010/11, when compared to the number of inhabitants at the Census 2011[1]. Besides the uncertainty in the future evolution of demographic behaviour, the socioeconomic context remains uncertain as well. Although Albania belongs to the few European countries that did not experience a recession since 2008, the main destination countries of emigrants are currently facing a financial, structural and political crisis. The length of this crisis will influence the future course of Albanian migration with significant consequences not only on population, but also on family livelihoods and economic development in the country through changing amounts of money sent from abroad.

Given this situation, an initial effort was invested in an analysis of population trends at the national and prefectural level in the past, including international comparisons, to formulate the hypotheses underlying the forecasts. This was made possible by the increasing availability of demographic data produced by INSTAT over the last fifteen years, enabling a more accurate measurement of Albania's post-1989 demographic history. This preparatory work, combined with expectations about Albania's prospects in terms of socioeconomic and political development, forms the basis for the assumptions of reasonable demographic trends in the future. The projections horizon is limited to 20 years until 2031, and three different scenarios of population trends inform on the extent of uncertainty (the medium scenario is extended until 2060). Compared to previous projections rounds of INSTAT, this third round uses a slightly different methodology to better forecast emigration and is geographically more disaggregated as results are provided for each prefecture of Albania.

The section immediately following this introduction, briefly reviews demographic trends in Albania and its prefectures. We then introduce the projections methodology and discuss the hypotheses referring to fertility, mortality and migration, which are combined into three different scenarios of national population change. The medium growth scenario is then regionalized and differentiated by three plausible scenarios of internal migration to project the populations of Albania's prefectures. The forecasts at the national and prefectural level are described and discussed, their sensitivity to the underlying hypotheses analysed and the main components of future demographic change in Albania are identified. The report concludes with a summary of the main results.

(1) The first and second rounds expected 3.8 and 3.2 million residents, respectively, against an estimated number of 2.9 million.

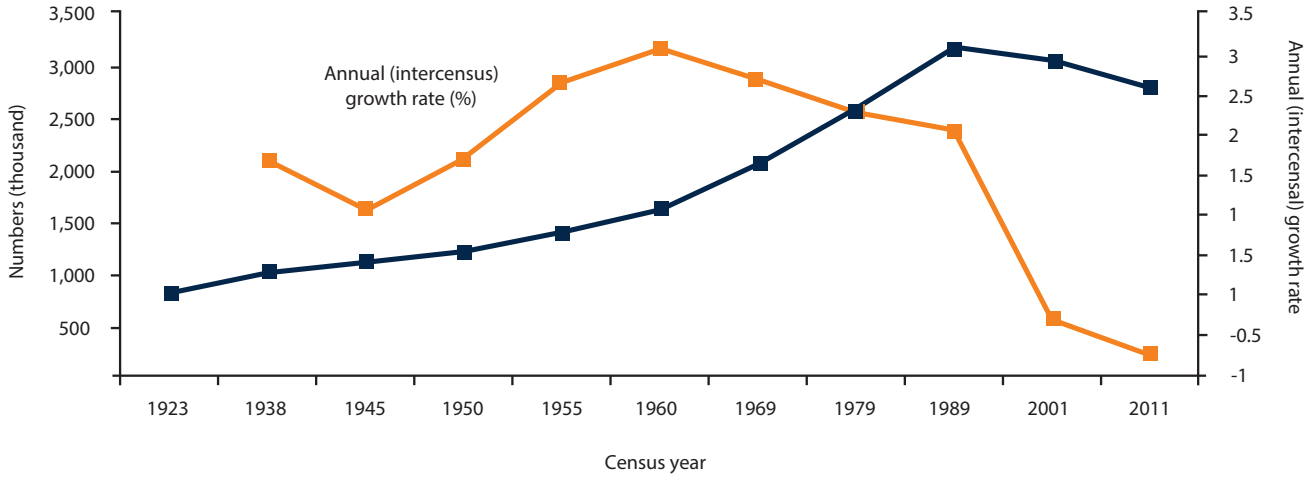
2

Recent demographic trends in Albania

TRENDS IN POPULATION AND AGE STRUCTURE

Albania experienced a late onset but a rapid pace of demographic transition (i.e. the sequential fall in the levels of mortality and fertility). If mortality started to decline since the 1930s, fertility remained high until the 1960s. The country therefore evinced among the highest growth rates in post-war Europe (above 2% annually), leading to an increase from 1,218 thousand residents in 1950 to a peak of 3,182 thousand in 1989 (Figure 1). Yet despite a young age structure, the population declined to 3,069 thousand in 2001 and 2,907 in 2011, which corresponds to an annual decrease of 0.3 and 0.8%, respectively. Emigration and lower birth rates were the main determinants of this population reduction.

Figure 1. Total population numbers and growth rate (in %) in Albania, 1923-2011



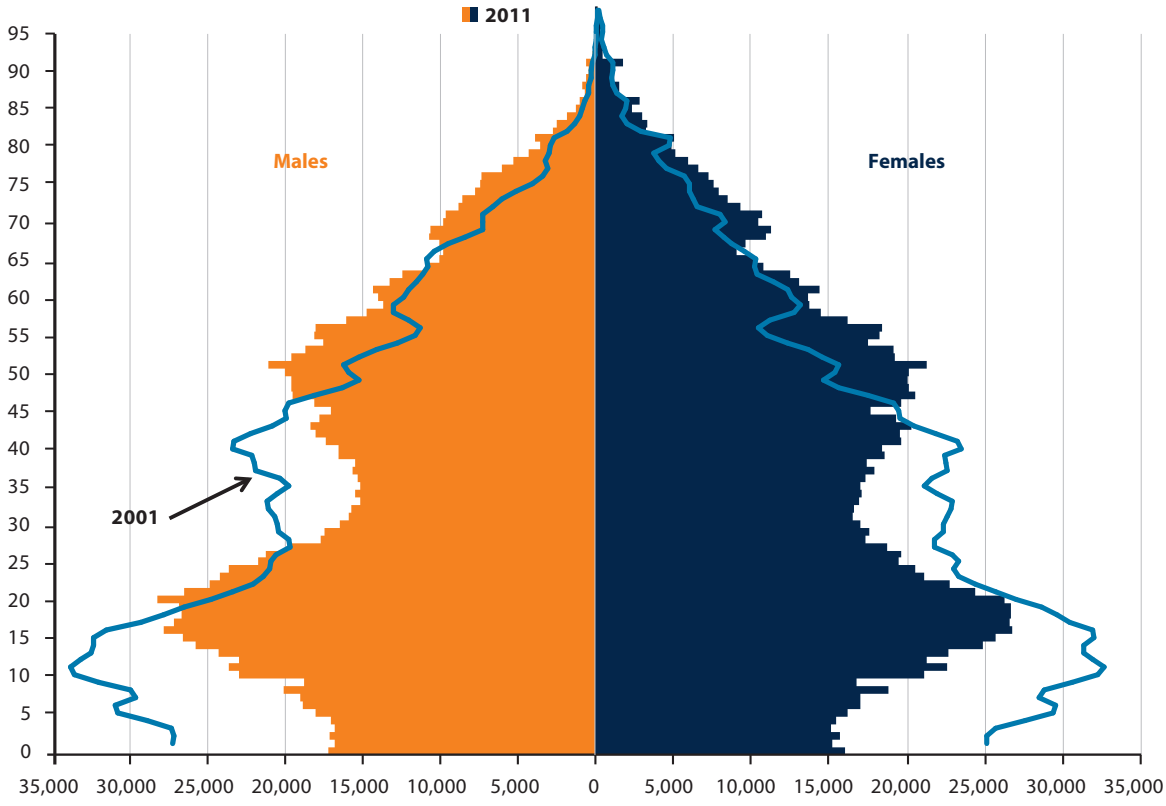
Sources : Population Censuses of Albania.

As in most countries of the Western Balkans, behavioural changes in fertility and migration have strongly affected the age and sex structure of the Albanian population (Figure 2). The irregular shape of the population pyramid evinces how demographic behaviour in the past affected the size of the successive birth cohorts surviving within Albania (which are plotted in Figure 2 according to sex and age attained in 2001 and 2011). The marked hollow (or indentation) in the middle of the pyramid testifies to the high emigration of young adults, especially men.

Compared to 2001, when women were more numerous than men because of a strong male dominance in emigration, the numbers are more balanced in 2011 because of an increasing participation of women in the migratory phenomenon – especially among young adults. There is actually an over-representation of males among the population aged 20-29 (the sex ratio is 111 men for 100 women).

Cohorts in childbearing age (20-44 years) were not only depleted by large scale migration, but also had lower fertility. As the number of births progressively declined, the base of the pyramid narrowed. An increasing over-representation of boys relative to girls is also visible. This can be related to the sharp increase in the sex-ratio at birth (there were 110 male for 100 female births in 2010), which paralleled the declining fertility levels since 1989 in a social context characterized by gender inequality and a culture emphasising the importance of having at least one son (UNFPA 2012).

Figure 2. Age and sex pyramid of the population of Albania, Census 2001, 2011



Sources : Population census of Albania 2001 and 2011.

Emigration of young adults, fertility decline, as well as lower mortality since 1989, have reduced the relative weight of younger cohorts and increased that of older ones in the total population, leading to demographic ageing (Table 1). The proportion of persons aged less than 15 years decreased from 33% to 21% between 1989 and 2011, whereas that aged 65 and over increased from 5% in 1989 to 11% in 2011. Thus, in 2011, one child was supported by three individuals of working age (i.e. aged 15 to 64), compared with two in 1989. Conversely, there is one older person for six individuals of working age, down from more than eight in 2001. Albania is indeed experiencing a substitution of old age to young age demographic dependency.

Table 1. The age structure of Albanian population, Censuses 1979-2011, in (%)

Age Group	Census years			
	1979	1989	2001	2011
0-14	37.0	33.1	29.3	20.7
15-64	57.8	61.6	63.2	68.0
65 and above	5.3	5.3	7.5	11.3

Source: Population Censuses of Albania.

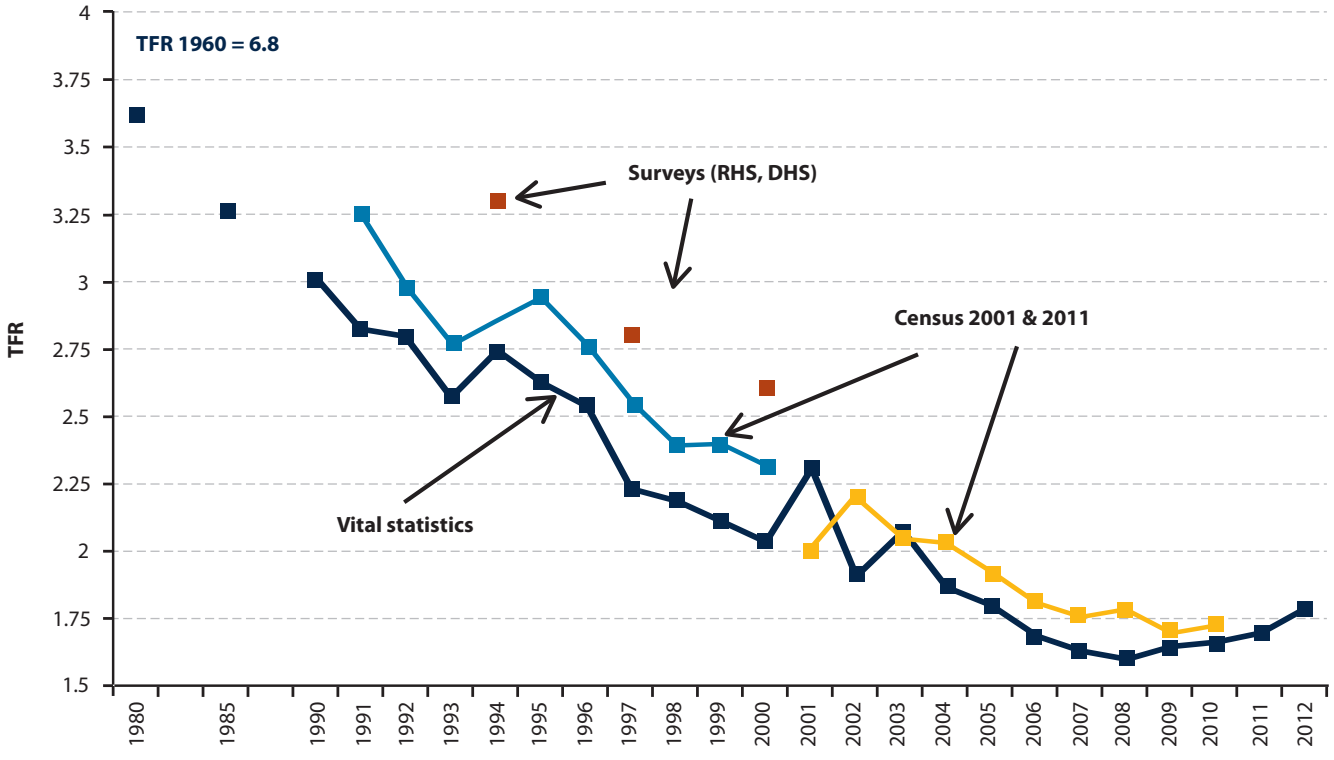
Yet the Albanian population remains among the youngest in Europe, with a median age[2] of 32.6 years in 2011, which still contrasts with an EU 27 average above 41 years (Eurostat). Nevertheless the transformation of population ageing has major economic implications. The societal cost of supporting an older person is indeed higher than the average support to a child (ONS UK, 2008). Demographic trends must therefore be closely monitored.

(2) The median age is the age at which half of population is younger and the other half older.

FERTILITY

The average number of children per Albanian woman remained the highest in European comparison until 2001, even if the total fertility rate (TFR; see Glossary in Appendixes) dropped at a fast pace from 6.8 in 1960 to 2.3 in 2001. During the last decade, fertility fell under the level required for a couple to reproduce itself (i.e. the generational replacement level: 2.1 children per couple); it reached 1.7 in 2011, according to vital statistics (Figure 3). Consequently, the number of births in 2011 was less than half that in 1990 (i.e. 34,285 compared to 82,125). Although indirect estimations of fertility from the 2001 and 2011 Censuses and sample surveys consistently indicated higher levels, the declining trend is confirmed. The divergences between sources also narrowed substantially over the years, testifying to the improved measurement of fertility in Albania. However, it is interesting to note that vital statistics suggest a slight recovery of fertility since 2008.

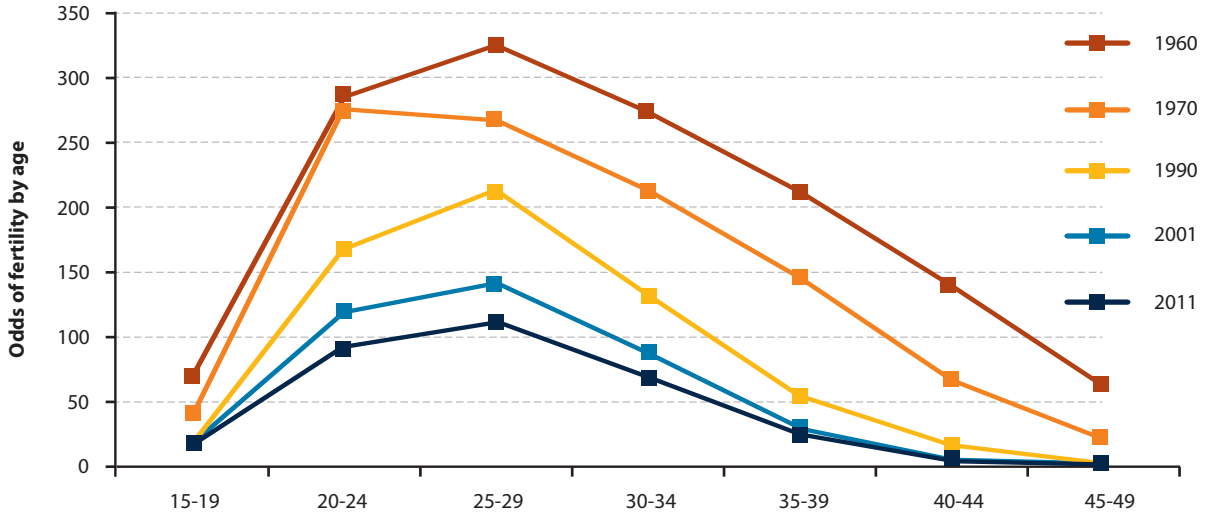
Figure 3. Evolution in the total fertility rate (TFR), Albania 1980-2012



Sources : Population census of Albania 2001 and 2011, vital statistics and surveys

Fertility declined in all age groups, but the fall was more pronounced at ages 35 and above before 2001 (Figure 4). Women married at young ages (on average at 22.4 years in 2001) and the use of mainly traditional methods of birth control aimed to limit family size rather than to postpone the first births (Falkingham and Gjonça 2001; INSTAT et al. 2010). Albania's historical fertility decline can be related to the diffusion of higher level education, to the social and cultural changes emphasising less traditional attitudes in family life and maybe to the economic restrictions of the families. The level of fertility was indeed lower by at least one child in urban areas when compared to rural areas in the past (Dumani 1995). According to the 2011 Census, women aged 45 to 49 with at best a primary school diploma had born on average 3.3 children, against 1.7 among those of the same age with university education.

Figure 4. Age-specific fertility rates (per 1000), Albania 1960-2011



Sources : Vital statistics and Censuses 2001 and 2011, Dumani (1995) for earlier periods.

After 2001, by contrast, the reduction in birth rates was more concentrated at younger ages, because it was associated with an increase in the average age at first marriage of women to 24 years. Consequently, women started to bear their children at older ages than before (i.e. fertility is postponed; Lerch 2013a). Higher-educated women again initiated this trend, with only 16% being married at age 20-24 against 43% among the lower-educated in 2011. The recent transformations of Albanian fertility reflect the increase in higher level education, increasing opportunities or difficulties in the labour market, and, maybe, the rising importance of individualistic values and self-realisation as observed in Western Europe, which all postpone family formation. However, the changes in living arrangements that reflected these transformations in values about family life throughout Europe are not yet significant (in Albania i.e. only 1.2% of women in childbearing age live in non-marital cohabitation (Dumani and Subashi 2011).

Although Albania seems to follow the European trend in fertility decline and postponement, the average age at marriage remains low and the fertility level high, compared to other countries in the region (the TFRs range between a low 1.3 in Romania and a high 2 in Kosovo in 2009; Eurostat; KDHS 2009) This can be explained by the later onset of fertility transition in Albania, meaning that there is room for further birth limitation and postponement.

MORTALITY

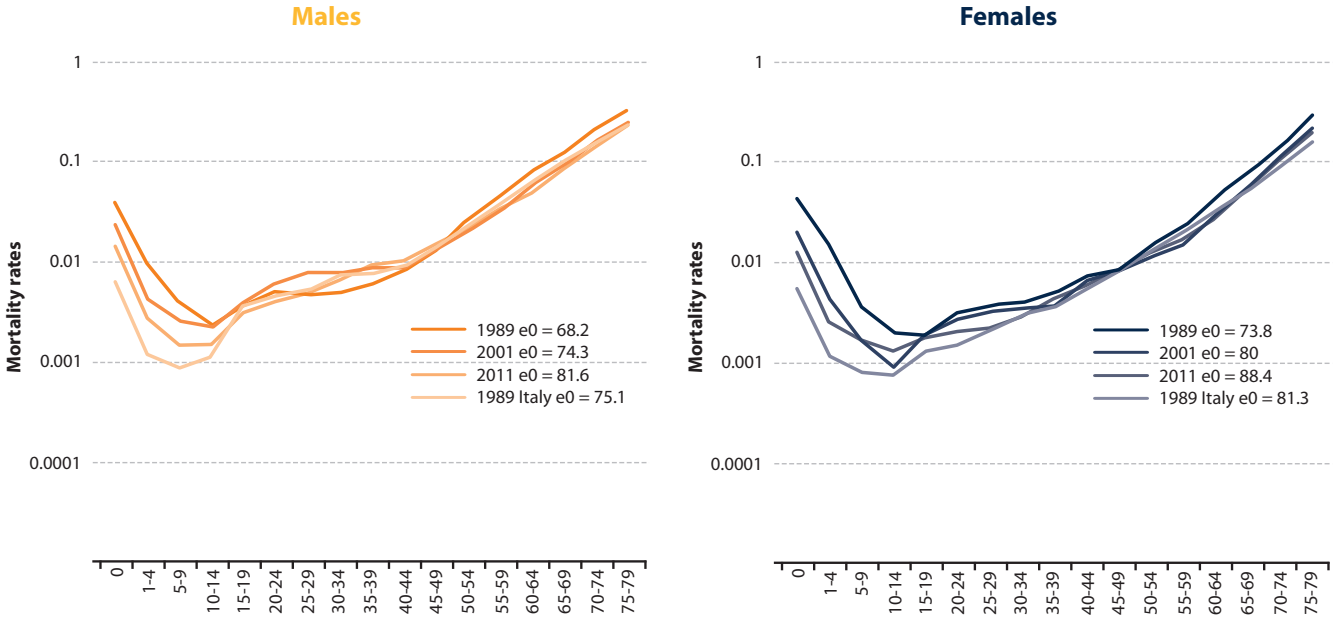
Due to major improvements in the sanitary system and public health since 1950, Albanian mortality declined steadily at all ages. Between 1950 and 1989, life expectancy at birth[3] increased from 51.9 to 67.9 years for men and 51.3 to 73.9 years for women (Gjonça 2001). Despite the differences in socioeconomic development with other countries in Europe, the adults' health conditions were comparable (life expectancy at age 25 was 48.3 years for men and 54 years for women in 1989). Gjonça (2001) suggested that the Mediterranean diet acted as a protective factor against the risk of mortality.

Adult mortality continued to decline until 2011, with life expectancy at age 25 reaching 51 years for men and 56 for women. The total number of deaths nevertheless slightly increased from 18,193 in 1989 to 20,012 in 2011 because more numerous birth cohorts reached older ages, at which point mortality increases rapidly.

Infant mortality, by contrast, was among the highest in Europe, despite a sharp fall since 1989. Yet recent estimates differ according to the sources. Vital statistics suggest that the number of deaths before reaching the 1st birthday decreased from 47 to 9 per thousand male births and from 43 to 8 per thousand female births in 2011 (Figure 5). Indirect estimations from recent Population Censuses and surveys, however, indicate at least twice that level for the 2000s (18 deaths for both sexes, according to the ADHS 2008-09).

To construct the entire life table of 2011, we therefore combined the ADHS estimates of infant and child mortality with death rates at older ages based on vital statistics (see Methods in the Appendixes). According to these estimates, life expectancy at birth continued to increase during the 1990s by more than four and less than five years for males and females, respectively (Figure 5). During the 2000s, however, the progress was slower, but more marked among men, when compared to women: life expectancy increased from 72.9 to 74.5 years for the former between 2001 and 2011, against 78.6 and 79.3 years for the latter. Hence, male mortality started to converge towards the lower female level.

Figure 5. Life expectancy at birth (e0) and age specific mortality rates by sex, 1989, 2001, and 2011



Sources : Gjonça (2001), Vital statistics, RHS, DHS, Censuses 2001 and 2011.

(3) The average number of years a newborn can expect to live (see Glossary in Appendixes)

The recent decline in mortality was stronger among young children. According to our adjusted estimates, male infant mortality decreased from 26 per thousand in 2001 to 19 in 2011, while the female rate declined from 20 to 16 per thousand live births, respectively. Despite these major improvements in child health, Albania continues to evince among the highest child mortality levels in Europe, following Kosovo with 23 deaths per thousand live births (KDHS 2011) and close to the levels observed in Macedonia, Montenegro, Bulgaria and Romania.

If mortality also declined at older ages, death rates stabilized among young women and increased among young men during the 1990s. A similar but more marked trend was observed in other post-communist countries. In Albania, increased road traffic-related mortality due to the diffusion of cars have also played a role, as well as the rise in crime during the 1990s (Gjonca 2006). However, recent estimates suggest a renewed decline of mortality at these ages.

Circulatory diseases remain the main causes of death in Albania, with a three to four times higher risk of mortality than from tumours. The cause-of-death structure of Albanian mortality is similar to that in Bulgaria, Romania and Macedonia. This contrasts with countries in Southern and Western Europe where tumours are at least as important for mortality when compared to circulatory diseases, the risk of mortality of which declined due to developments in diagnosis, therapy and prevention (WHO 2010).

INTERNATIONAL MIGRATION

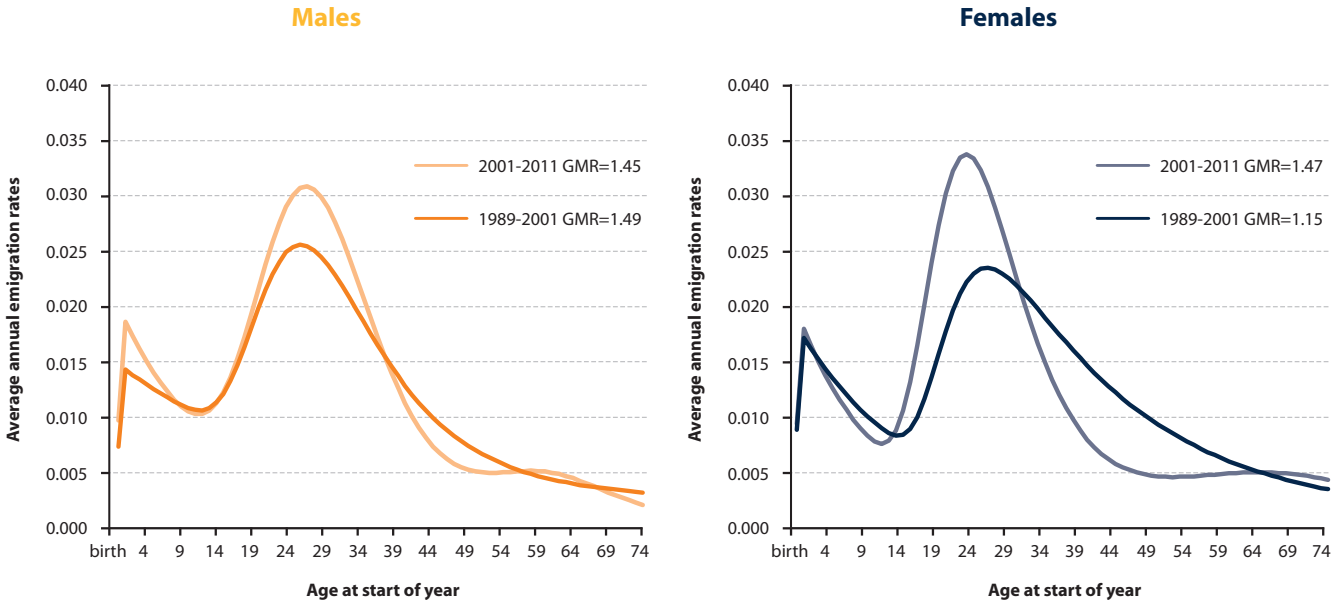
Subsequent estimates of the number of Albanians living abroad testified to the massive scale of emigration. The net migration stock increased to 220,000 in 1992 and more than 600,000 in 2001 (INSTAT 1999, 2004a). An additional net migration balance of 450,000 was estimated for the last decade (see Migration Report). Thus, an annual average of at least 50,000 individuals left Albania during the 1990s and 2000s (which represented 1.4% of the total population every year). As with Moldova, Albanian emigration is by far the highest in European comparison.

Although males initially dominated the outflow, there is an increasing feminization of emigrants; the sex-ratio of the net migrant stock aged 15-39 decreased from more than 5 men for 1 woman in 1992 to approximately 2 men for 1 woman in 2001. In the last decade, the male flow did not level off, but women experienced an increase to such an extent that they dominated net migration (see Migration report).

The age profile also changed between the two decades. Figure 6 presents annual age-specific rates of emigration for each sex, which have been estimated indirectly from two successive Population Censuses (immigrants are not considered here; see Methods in the Appendixes). The gross-migraproduction rate (GMR) is also shown: similar to the TFR, this indicator can be interpreted as the number of emigrations an individual can expect during his life under current migration patterns. During the 1990s, migration was dominated by young adults although individuals aged 40 to 60 significantly participated to the outflow, as well – in particular women. The crises may have pushed entire families abroad. During the 2000s, emigration became more selective as it concerned young adults aged 20 to 30 years to a greater extent – especially among women. Thus, attractive factors abroad – such as economic opportunities, social amenities and previously emigrated family members – may have played a stronger role than push factors in the migrant decision, when compared to the 1990s.

In particular, the increase in female emigration appears related to family reunification abroad, although other factors such as student and professional mobility may also matter. According to the ADHS in 2008/9, 61% of female emigrants indeed moved for family-related motives and 26% for work, contrasting with a dominant labour migration among men; (INSTAT et al. 2010). This does not mean, of course, that women do not work abroad, but that their opportunity to emigrate is tied to prior departures of other family members to a greater extent than men's. Women also left Albania at younger ages than men (with an earlier and higher peak in emigration rates at age 22 against the men's at 26-7 years). Although this difference is equal to the traditional age gap between spouses who move jointly, the peak age for women is closer to their average age at marriage when compared to men, which points to an increase in international marriage migrations among women.

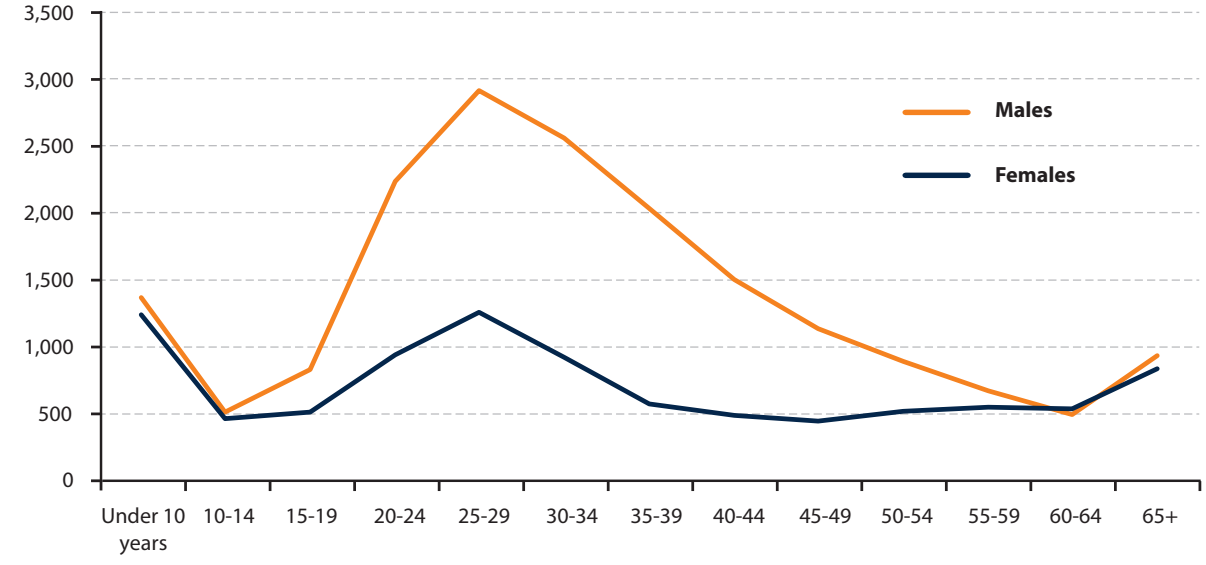
Figure 6. Average annual emigration rates by sex and age, Albania 1989-2001 and 2001-2011, in (‰)



Sources : Population censuses of Albania 1989, 2001, 2011.

Information on immigrants concerns mainly return migration and was scarce until recently. According to the Census 2011, the number of Albanians who ever resided abroad and returned increased from 5,000 in 2001 to 36,000 in 2011, which remains low compared to the number of departures. Factors explaining this increase are unclear. We can however mention the consequences of the Italian and Greek crises. Yet, only about 15% of Albanians living in Greece in 2012 planned to return since the onset of the crisis (Gëdeshi and De Zwager 2012). Moreover, the increasing number of border crossings from Greece (the flow in 2008-2012 represented one fifth of the Albanian population in that country; ACIT and USAID 2012), may enlarge the pool of new candidates of emigration. The majority of returnees are composed of men aged 20 to 39 years (Figure 7).

Figure 7. Returnees in 2011 by age and sex, Albania 2011



Sources : Census 2011.

Women participated to a limited extent in return migration. This is not surprising as more men than women resided abroad and that especially male migration at young ages is characterized by several subsequent short-term trips abroad. Figure 7 suggests that female returnees generally move with their children in contrast to the more frequent independent returns among men. The current crises in Greece and Italy may motivate dependent family members to move back in an attempt to alleviate the costs of living for migrants abroad.

DEMOGRAPHIC CHANGE IN ALBANIA'S PREFECTURES

A detailed analysis of demographic trends at the prefectural level can be found in the Appendixes. Here, the main results are summarized. Demographic decline concerned all prefectures, except Durrës and Tirana because they experienced lower emigration and absorbed the majority of internal migrants. Similarly to the 1990s, the depopulation was strongest in the peripheral prefectures in the South and the North during the 2000s (especially for Gjirokastër, Berat, Kukës, and Dibër).

Population ageing is most pronounced in the South (Gjirokastër, Korçë, Vlorë, Berat), because the region initiated the historical decline in fertility and evinced the highest rates of emigration since 1990. These prefectures shifted rapidly from a dominant young age to old age dependency – as observed in Western Europe since 2005 as well as in Croatia, Slovenia and Bosnia-Herzegovina more recently.

The decline in death rates was observed throughout Albania, so that the geography of mortality did not change compared to past periods. The regional convergence towards lower fertility levels observed in the 1990s (Lerch et al. 2010), continued during the 2000s. In 2011, the TFR was below the level required to replace the current generations in the future (i.e. under 2.1) in all prefectures.

Opportunities to emigrate abroad also diffused throughout Albania in the 2000s, including to the Northern regions. International departures clearly dominated out-migration in all prefectures – except Kukës and Dibër, where both types were similarly important. The age patterns of emigration were similar and there was an almost equal participation of men and women across all prefectures. The levels of out-migration to another prefecture also converged across prefectures (including an increase in the South). Migrants were predominantly selected among young adults in the 2000s – mainly women around the age of 20. As in the case of international migration but to a higher extent, internal migration is increasingly related to major life course transitions, such as moving related to work, higher level education, or marriage (especially for women). Thus, Albanian migration transformed from a temporary and crisis-led phenomenon into a more permanent and opportunity-seeking behaviour linked to a marital or family life project in all prefectures.

International immigration (representing mainly return flows of emigrants) remained focussed on more urbanized areas – particularly those located on the coast. Internal migrants also still predominantly moved to Tirana and Durrës prefectures. These trends, combined with emigration from peripheral areas, strongly increased the level of urbanisation in Albania (from 36% in 1989 to more than 50% in 2011) and accentuated the concentration of population in Tirana and Durrës prefectures, where 36% of inhabitants resided in 2011, against 22% in 1989.

3

Methodology and Assumptions

PROJECTIONS METHODOLOGY

Demographic change occurs when individuals arrive from elsewhere and couples bear children, adding new members to the population, whereas others die or depart to other places, which depletes it. Because these demographic events affect the population of different sexes and ages, they determine both the number and structure of a population. The main objective of every demographic prospect is to determine how births, deaths and migrations will occur during the next year. The methodology adopted for this third round of INSTAT's population projections – the cohort component model – calculates these events for each year and age-sex group under the assumption of plausible future trends in mortality, fertility and migration in the future. These events are subtracted and added to the population in the beginning of the year, providing the population by age and sex at the start of the next year, and so on.

The number of demographic events depends on both the population structure and demographic behaviour (i.e. the number of births depends on the number of women in childbearing age and their rate of childbearing). As population structure and demographic behaviours are known at base-line (from the Census 2011 and the previous analysis, respectively), future trends in demographic behaviour were projected based on hypotheses that rely on our knowledge of the demographic situation, past trends, the socio-economic and political context and international comparisons (see next section).

The population by age and sex at base-line of the projections, 1st January 2011, is estimated by INSTAT through retropolation of the enumerated population on 1st October 2011 (taking into account recent emigration and immigration, as well as the rate of under-enumeration).

The national population by sex and single age is projected iteratively year after year in the following manner, starting with the population at 1st January:

- The number of deaths is estimated for the first six months in applying sex and age-specific death rates to the population on 1st January; the deaths are subtracted from population to obtain the survivors at mid-year (30 June);
- The annual number of emigrants by age and sex are estimated from this mid-year population using emigration rates, and these events are then subtracted; an assumed number of immigrants by sex is redistributed by age and added to the population.
- The number of deaths for the second semester is then estimated and subtracted from this revised mid-year population, yielding the number of survivors on 31st December;
- The number of births is estimated in multiplying age-specific birth rates to the average number of females in reproductive age; infant deaths and emigrants until the end of the year are estimated and subtracted from the number of births;
- To project the population on 1st January of the following year, each cohort is moved forward by one year of age to account for population ageing, and the number of surviving births within the country constitutes the first age-group.

Prefectural population by sex and 5-year age groups are projected iteratively and simultaneously over 5-year intervals using a cohort component multiregional migration-pool model, which was adapted from the multiregional model proposed by the U.N. (United Nations 1992). The procedure involves the following steps for each prefecture:

- The sex and age specific population at the start of the projections interval are forward-survived by 5 years,
- Surviving emigrants (abroad) and out-migrants (to other prefectures) are successively estimated using migrant transition rates (net of mortality, and international migration in the case of out-migration) which are applied to the population at the end of the interval. Emigrants are subtracted from the population and out-migrants are pooled by age and sex, providing the number of in-migrants to redistribute.
- The pooled number of in-migrants, as well as an assumed number of immigrants (from the national level projections) are added in the end. These were redistributed by prefecture according to their respective geographic distribution (by age and sex) in 2006-2011.
- Births are estimated in applying age-specific fertility rates to the average population in the beginning and end of the 5-year interval and are forward-survived to the end of the interval
- To obtain the population on 1st January at the start of the following 5-year interval, each cohort is moved forward by five years of age to account for population ageing; the number of surviving births within Albania constitutes the first age group.
- The sex- and age-specific populations and demographic events at the prefectural level are constrained to sum up to the totals projected by the national projections.

HYPOTHESES ABOUT FUTURE FERTILITY, MORTALITY AND MIGRATION

To provide a range of plausible future trends of Albania's population and to represent the uncertainty of projections, different hypotheses on mortality, fertility and migration were defined.

Fertility assumptions

The recent increase in the TFR evinced by vital statistics adds uncertainty regarding the future path of fertility. On the one hand, it may represent a short-term fluctuation – as observed in the past in Albania and most other countries of the Western Balkans. Fertility is indeed determined by competing social influences – including structural change in the labour market, increased schooling, value change, but also influences of traditional social institutions such as the extended family and patrilocal culture – which can produce irregular paths of decline. On the other hand, the recent increase may also be a precursor of a prolonged recovery as evinced by Mongolia – although the upward trend was motivated there by the implementation of a proactive family policy, which is not the case in Albania. To reflect this uncertainty in the projections, three hypotheses of the future trend in fertility were defined. As all hypotheses expect that women will have their births at older ages in the future (i.e. postponement), they mainly differ according to the trend in the average number of births per woman (TFR).

The *low fertility hypothesis* is based on the long-term trend and suggests a continuing convergence towards the European pattern. We expect a similar decline as in the previous projections round (INSTAT 2004), which actually forecasted quite well the level of fertility for 2011. The TFR should decrease from 1.73 in 2011 to 1.3 children per woman in 2026 (Table 2). A similar pace was observed in Portugal and Macedonia in the past.

Following a trough in the TFR in 2026, we expect a recovery to 1.4 due to the recuperation of births at older ages, which have been previously deferred at younger ages. Many countries of Western, Central and Eastern Europe indeed experienced such an increase in fertility since 2003 (Eurostat 2013). Congruent to the expected birth postponement and subsequent recuperation, we forecast an ageing of fertility (as well as an initial concentration, followed by a deconcentration of age-specific rates around the mean age at birth).

This convergence of Albania towards the dominant childbearing pattern of Europe can be expected alongside the continuing process of modernization of society. A convergence of the higher rural fertility towards the urban level is supposed (the respective TFRs were 1.9 and 1.3 in 2007, according to the ADHS), as well as the adoption of the urban standard of childbearing by rural-to-urban migrants. This low hypothesis implies a continuing increase in higher level education, and a higher participation of women in the labour market, which complicates the reconciliation of ideal family-size with professional responsibilities.

The effects of a potential economic crisis would also sustain fertility postponement and decline, as observed in Europe (Goldstein 2013). Besides negative income effects, strong family connections also motivate young couples to take care about the health and financial situation of their parents, or other retired family members, which may lead to a postponed and limited fertility among the young generation. Moreover, emigration of young men leads to later marriages and/or spousal separation, which may also postpone births. The likely return of more emigrants after 2026, by contrast, can also be related to the recuperation of fertility when couples reunify in Albania (Dumani and Subashi 2011).

Table 2. Low, medium and high fertility assumption, Albania 2011-2031

	2011	2021	2026	2031	2060
TFR					
Low	1.73	1.44	1.30	1.40	
Medium	1.73	1.61	1.56	1.50	1.50
High	1.73	1.91	2.00	2.10	
Annual change in the mean age at birth					
Low	0.05	0.05	0.20	0.20	
Medium	0.05	0.03	0.03	0.03	0.00
High	0.05	0.05	0.05	0.05	
Annual change in the variance of age at birth					
Low	-0.30	-0.30	0.20	0.20	
Medium	0.00	-0.20	-0.20	-0.20	0.00
High	0.05	0.05	0.05	0.05	

The *medium hypothesis of fertility* takes into account the recent trend since 2008, evinced by vital statistics. This increase is considered as part of a fluctuating trend around a less steep decline than in the low hypothesis: a TFR of 1.61 is expected for 2021 and 1.5 in 2031. Because of continuous birth postponement, the entire fertility rate schedule is moved to higher ages.

The *high fertility hypothesis,* interprets the recent upward trend as a prelude of a long term recovery. The TFR is expected to reach the generational replacement level (2.1) in 2031, which actually corresponds to the current level of cohort fertility. This assumption supposes different social forces in Albania will slow down the social diffusion of childbearing patterns found elsewhere in Europe. Patrilocal culture and gender inequality remains important and continues to promote larger families through social influences on reproductive behaviour of young women (Lerch 2013b). This may be particularly the case in rural areas, where grand-parents and other family members live with or near to the younger generation, thereby supporting childbearing and child-raising. Moreover, fertility was also high in clustered in-migrant neighbourhoods of cities, where rural socialization is often reproduced (Lerch 2013c). Thus adaptation to urban reproductive standards may last more than one generation. Remittances sent by emigrants may also enable couples to afford more children and thus to realize their ideals in terms of family size. According to the ADHS 2008/9, the ideal number was still 2.6 children and only a fifth of women with one child intended to stop childbearing (INSTAT et al. 2010).

Age-specific fertility rates are modelled using a gamma function determined by three parameters, for which we forecasted trends according to the hypotheses above: the level (TFR), timing (mean age at child birth), and concentration of fertility in age (the variance in age at birth).

The sex ratio at birth is expected to level off to the biological level in the future, starting from 110 male to 100 female births in 2011.

Mortality assumptions

Sex- and age-specific mortality rates are projected from the observed levels in 2011 using fixed rates of improvements based on the trends observed during the last 10 years in Albania and past experiences in neighbouring countries (Macedonia and Italy). A slow decline in mortality is anticipated with smaller improvements at higher ages, when compared to children, because the level is already low. The decline should be driven by a more healthy life style (including lower alcohol and tobacco consumption and fewer accidents), as well as by developments in medical (and bio-) technology which may particularly reduce mortality from cardiovascular diseases which is the principal cause of death in Albania. Increasing effectiveness of the health care system and better sharing of health information among the population as well as between institutions should sustain this trend. The recent trend of convergence in male mortality to the lower levels among women is expected to continue in the future.

The low hypothesis assumes the following annual rates of reduction in female death rates: 7% for infants, 5% for children aged 1 to 4, 3% for the age groups 5 to 59, and 1% at older ages. The medium mortality hypothesis assumes an annual

reduction of respectively 5%, 2%, 1.5% and 1%. The corresponding rates of change assumed by the high mortality hypothesis are 3.5%, 2%, 1.2 and 1%. These rates of decline in death rates are increased by 0.5 percentage points for men to project a mortality convergence between the sexes.

Thus, the low hypothesis implies infant and child mortality to decline by half over each of the periods 2011-2021 and 2021-2031, resulting in a final mortality of one fourth 2011 level (Table 3).The medium hypothesis assumes a convergence to the level of infant mortality observed in Italy around 2000, while the high assumption implies a convergence to Italian standards of 1996. In the extension of the medium hypothesis for the period 2031-2060, annual rates of reduction of death rates above age 4 are kept constant, whereas child mortality remains unchanged.

Table 3. Low, medium and high assumptions of infant mortality (per 1000 live births), Albania 2011-2031

	Low			Medium			High		
	2011	2021	2031	2011	2021	2031	2011	2021	2031
Male	15.9	7.1	3.2	15.9	9.0	5.1	15.9	10.1	6.4
Female	12.9	6.1	2.9	12.9	7.7	4.9	12.9	8.9	6.2

Under these assumptions, male life expectancy ranges between a high 79.3 years and a low 77.4 years in 2031, with a medium forecast of 78 years (Table 4). Women's life expectancy ranges between 81.5 and 83, with the medium forecast of 81.9 years.

Table 4. Implied life expectancy at birth by the low, medium and high assumptions of mortality

Year	Low		Medium		High	
	Male	Female	Male	Female	Male	Female
2011	74.4	79.2	74.4	79.2	74.4	79.2
2021	77.2	81.4	76.6	80.8	76.2	80.7
2031	79.3	83.0	78.1	81.9	77.4	81.5
2060			81.1	84.1		

International migration assumptions

Given the past two decades of large scale emigration, diffused throughout Albania, all hypotheses assume a generally decreasing trend for the next twenty years. In several countries having experienced intense emigration flows (such as in South Korea, Mexico or Morocco), the flow levelled off after at least 15 to 20 years (De Haas 2007). Many peripheral areas already experienced a strong depopulation and the incentives of emigration are expected to decline in the future. In the same time, transnational labour circulation with Italy and Greece should reduce, as Albanian migration transforms from a male-dominated into a marital or family project – although education plays an important role as well. Given the equal levels of emigration for both sexes during the last decade, we assume similar trends in the future for men and women.

Immigrant flows are mainly constituted by return migrants. Their number recently increased with the crises in Greece and Italy but should decline later on in the projections horizon as the crisis fades away. Yet Albania may gain in residential attractiveness for emigrants abroad, as supposed in the hypotheses below. The extent of this attractiveness is assumed to depend on the pace of economic growth in Albania. Emigrants will also start to reach retirement age and, maybe, progressively return to Albania in the end of the 2020s. All assumptions expect higher emigration than immigration, so that net migration will remain negative, they mainly differ according to the pace of decline in emigration.

According to the *low migration hypothesis*, the rates observed during the 2000s are projected to decrease at a fast pace: by two thirds until 2021 (yielding a Gross migraproduction rate (GMR) of 0.5 for men and women; Table 5). As this year is an early estimate for Albania's accession to the European Union which will facilitate international mobility, emigration is expected to remain constant thereafter. The number of immigrants is expected to decrease from 24 to 8 thousand men between 2011 and 2021, and from 12 to 6 thousand women, respectively. These numbers are held constant until 2031.

Table 5. Low assumption of international migration (emigration rates and number of immigrants), 2011-2031

	2011	2021	2031
Emigration (GMR)			
Male	1.5	0.5	0.5
Female	1.5	0.5	0.5
Immigration (N)	36,408	14,000	14,000
Male	24,145	8,000	8,000
Female	12,263	6,000	6,000

This low hypothesis is based on expectations of positive trends for the Albanian economy, which may continue to avoid a recession. Rising foreign direct investments and a better mobilization of economic, financial and labour resources should lead to increased employment opportunities. Given an expected decrease in the wage-gap of Albania with Western European countries, the attractive forces abroad should diminish which also sustains return movements. Domestic destinations such as the growing urban economies will become an attractive alternative for people residing in the periphery.

More restrictive migration policy in Greece and Italy may further reduce opportunities of legal re-immigration. Therefore, emigrants who reside already abroad may stay there for longer periods in the future – leading to a stabilisation of the number of returnees. Thus, the typical come-and-go pattern of Albanian migration is expected to end.

The *medium migration hypothesis* expects a slower decrease in the intensity of emigration, with half the level observed in the 2000s attained in 2021 (i.e. a GMR of 0.7; Table 6). A less steep decline is expected until 2031 to reach the same level assumed in the low migration hypothesis (i.e. a third of the level in the 2000s). The expected number of immigrants is assumed to decline to 6,000 men and 4,000 women in 2021, remaining constant thereafter. The extension to 2060 assumes constant emigration rates and numbers of immigrations.

Table 6. Medium assumption of international migration (emigration rates and number of immigrants), 2011-2060

	2011	2021	2031	2060
Emigration (GMR)				
Male	1.5	0.7	0.5	0.5
Female	1.5	0.7	0.5	0.5
Immigration (N)	36,408	10,000	10,000	10,000
Male	24,145	6,000	6,000	6,000
Female	12,263	4,000	4,000	4,000

Such a slower decline in emigration and sharper drop in immigration implies a renewed attractiveness of neighbouring countries in the context of their economic recovery. Alternatively, migrants may head towards new destinations located at greater geographical distance from Albania – such as observed recently towards Great Britain and Germany (see Migration report). Moreover, families should continue to reunify abroad, especially when immigration policies restrict labour migration and complicate come-and-go movements. The higher level of emigration in the short run is also supported by the growing desire among the youth to study abroad.

The *high migration hypothesis* is more in line with the recent history of large-scale emigration, as it expects a downward trend. It anticipates a linear decline in the intensity of emigration by one half until 2031 (yielding to a GMR of 0.8; Table 7). The number of immigrants is forecasted to decline to a larger extent by 2021 than in the other hypotheses – to 5,000 men and 3,000 women – and remains constant thereafter.

This assumption supposes a relatively fast recovery from the Greek and Italian crises along with the diversification of migrant destinations, as well as a slower development of Albania's economy implying a slow convergence in wage levels with Western Europe. A high level of youth unemployment, in particular, may continue to motivate departures among the younger generations.

Table 7. High assumption of migration (emigration rates and number of immigrants), 2011-2031

	2011	2021	2031
Emigration (GMR)			
Male	1.5	1.1	0.8
Female	1.5	1.1	0.8
Immigration (N)	36,408	8,000	8,000
Male	24,145	5,000	5,000
Female	12,263	3,000	3,000

Annual sex and age-specific emigration rates are projected in scaling the rates observed in the 2000s according to the above hypotheses on the GMR, assuming an unchanged age pattern over the projections horizon. The relative distribution by age of the projected numbers of male and female immigrants is also held constant to the patterns observed in 2011.

Internal migration assumptions

The assumptions of inter-prefectural migration determine the trend in out-migration levels and the relative geographic distribution of migrants according to prefecture.

The *low internal migration hypothesis* expects a constant level in 2011-2016 (i.e. equal to the GMR of 2007-11), following a decline in all prefectures to half that level by 2031. Given the past 20 years characterized by a strong catch-up in the level of urbanisation, a slowing down of the process can be expected in the future.

According to the *medium internal migration hypothesis*, the 2007-2011 prefectural out-migration rates are held constant over the whole projections horizon. It is based on the prospect of a continuous flight of young people from the agricultural sector, student migrations which transform into long-term residence, as well as a continuing importance of patrilocal norms in household formation which should maintain high female migration at young ages. In all prefectures (but Dibër, Kukës and Gjirokastër) this still implies a continuously lower rate of internal migration when compared to the assumed decline in international emigration.

The *high internal migration hypothesis* is based on the idea of a substitutability of internal to international migration. As international migrations out-weighed internal departures in the recent past, the decline in the former can be assumed to parallel an increase in the latter: The GMR of out-migration is expected to increase by half in 2031, compared to the level in 2007-2011. Continuous economic development should increase the attractiveness of domestic cities, which absorb potential emigrants. Internal migration is expected to dominate emigration from 2021 on for women and 2026 on for men (except in Dibër and Kukës, where internal migration is dominant over the whole projections horizon).

In the *hypothesis spatial concentration of internal migration*, we assume a constant redistribution of the pool of in-migrants according to prefecture (by sex and age), as observed during the last 20 years. This assumption implies an unbalanced economic geography of Albania in the future, with Tirana-Durrës as the main centres of activity.

The *hypothesis of spatial deconcentration of internal migration* expects a more equal distribution of in-migrants across prefectures for different reasons. The educational system may decentralize with an increasing attractiveness of professional schools and universities located outside Tirana and Durrës, especially in Elbasan, Vlorë and Shkodër. Taking advantage of the lower costs of housing, migrants to Tirana may also more and more establish in Elbasan and commute

from there since a new road now links both cities. Assuming a decentralization of migration is also justified by the rising employment opportunities in the tourist sector along the coast, as well as by the intended political priority given to regional economic development – such as support to the agro-industry in the agricultural plain, and in Korçë. There is already evidence pointing to the emergence of a temporary labour migration from the North to the agricultural sector in the South (especially in Sarande). The attractiveness of land-locked prefectures in the South may also increase in the future if the project of a new road linking Tirana-Elbasan-Berat-Gjirokastër is realized. Finally, the hypothesis of a spatial deconcentration of internal migration is justified by the current process of administrative and fiscal decentralization in Albania.

These ongoing and expected developments should lead to a linear increase by 2031 to three times the 2011-percentages of in-migrants heading to Elbasan, Vlorë, Shkodër, and Korçë. The percentages of in-migrants heading to Gjirokastër and Berat is expected to double. The rising importance of these migrant destinations implies a decline in the share of in-migrants towards Tirana and Durrës from two thirds in 2011 to about 40% in 2031.

The sex-specific age-profile of out-migration rates is held constant by prefecture over the projections horizon, as is the age-distribution of in-migrants by prefectures. Moreover, the same level and trend in survival rates assumed in the national level projections were applied across all prefectures.

SCENARIOS

The different hypotheses on mortality, fertility and international migration were combined in three scenarios of population change up to 2031 at the national level. The *low growth scenario* combines a high mortality, low fertility and high emigration (and a lower immigration) (HLH). In the *medium growth scenario*, all medium hypotheses are retained (MMM), while the *high growth scenario* combines low mortality, high fertility and low emigration (and a higher immigration) (LHL).

The sensitivity of the results to the hypotheses is assessed through analytical projections. These are all based on the medium growth scenario but vary according to one single assumption– mortality, fertility, or migration – which is replaced by assuming either the low or the high alternative. A zero-migration projection is also implemented to illustrate the effect of the age structure on Albania's future demography and to provide information on the potential demand for jobs in the country.

The populations of prefectures are projected according to the medium growth scenario, which was regionalized at the prefectural level in assuming spatially undifferentiated rates of change in fertility and international migration in the future[4]. This is justified by the similarity in past trends of fertility by prefecture and the spatial diffusion of emigration throughout the country. Moreover, applying equal rates of change also takes into the fact that fertility and emigration should decline at a faster pace where initial levels are higher than where they are lower.

Thus, the prefectural-level growth scenarios differ essentially according to the expected trends in internal out-migration and the geographic redistribution of migrants within Albania. The hypotheses are combined into six medium growth projections, of which three are of main interest. The *low internal migration scenario* combines a low out-migration with a spatially more balanced geography of in-migration in the future (MMMLD). The *medium internal migration scenario* combines constant out-migration with a constant distribution of in-migrants – strongly focussed on Tirana and Durrës (MMMCC). The *high internal migration scenario* combines the high out-migration hypothesis with a constant distribution of in-migrants (MMMHC).

Moreover, three analytical scenarios aim at informing about the respective effects played on prefectural level population change of our hypotheses on the level and spatial distribution of internal migration. The *high (or constant) but spatially deconcentrated migration scenarios* assumes increasing (or constant) out-migration, but a decrease in the spatial concentration of in-migration. The *low but spatially concentrated scenario* assumes a decline in-migration, which remains however focussed on Tirana-Durrës.

(4) In the regional projections, we used indirect estimations of fertility for Tirana and Shkodër as we believe the official figure to underestimate the level (see the Prefectural analysis in the Appendixes).

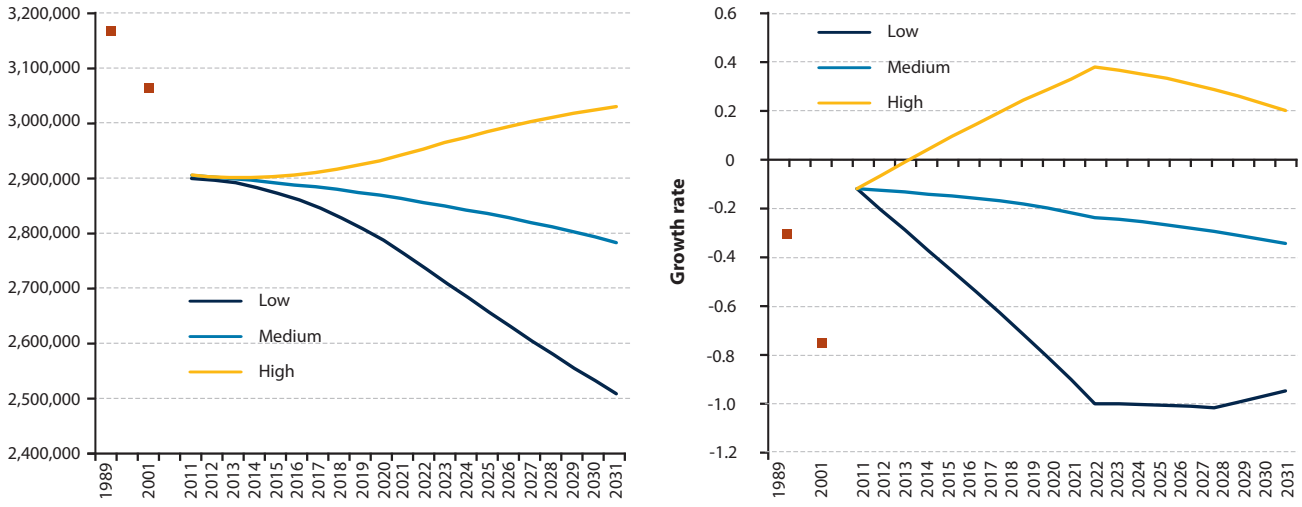
4

Results

FUTURE TRENDS IN ALBANIAN POPULATION

Albania's population should not reach its peak number of 1989 until 2031(see left-hand side of Figure 8). The medium growth scenario projects a slight decline until 2021 to 2,863,311 residents, followed by an intensification of the trend to reach 2,782,310 inhabitants in 2031. However, if fertility recovers from the actual level and emigration declines at a faster pace (as expected in the high growth scenario), the population should continuously increase to reach a high of 3,033,017 in 2031. The stronger fertility decline and emigration assumed in the low growth scenario should lead to a sharp decrease in the number of inhabitants to a low of 2,503,751 (see also the summary statistics in the Appendix Table 10). These three scenarios imply a range in the number of inhabitants representing between minus 14% and plus 4% of the residents population in 2011.

Figure 8. Trends in the number (left-hand side) and rate of growth (right-hand side) of Albanian population, 1989-2031

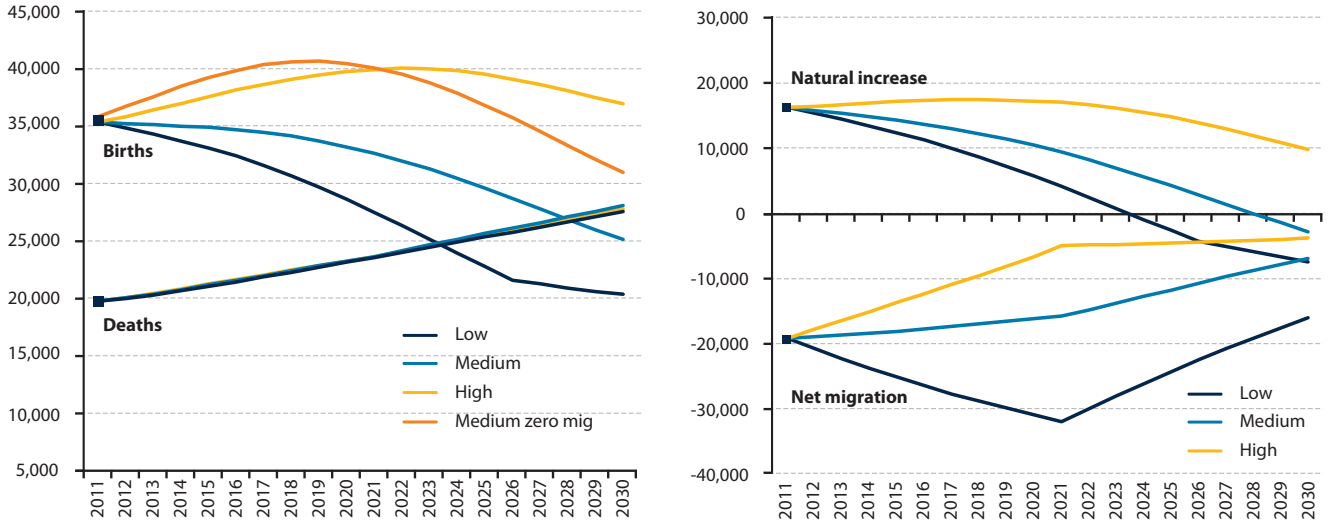


The high and low growth scenarios imply different future demographic trajectories for Albania, especially during the first projections decade, which is followed by a period of rather constant growth (see right-hand side of Figure 8). According to the high scenario, the annual growth rate of the total population should recover from its negative level in 2011 to a positive 0.4% in 2022 and then slightly decline to 0.2% in 2030. According to the low scenario, the rate of depopulation linearly declines in the first ten years and remains stable thereafter (at -1%). If the decline in fertility and emigration is slower (i.e. the medium scenario), Albania should experience a less steep drop in population growth to reach less than -0.4% in the end of the projections horizon.

A closer look at the components of population growth shows that there are little doubts about the linear increase in the number of deaths, from 19,804 in 2011 to 28,212 in 2031, with very small differences between the scenarios (left-hand side panel of Figure 9). However, the annual trend in the number of births differs substantially. The medium growth scenario forecasts a relatively stable annual number until 2017 (i.e. above 34,000) and a decline thereafter to a low 25,223 in 2030. If fertility increases continuously and emigration declines rapidly, by contrast, the number of births should rise to a peak of 40,204 in 2022 and decline only slightly until 2030. Assuming a strong decline of fertility and high levels of emigration implies a sharp and continuous decline in births to reach a low 27,165 in 2030.

The difference between the numbers of births and deaths is equal to the natural increase, which is plotted in the right-hand side panel of Figure 9. The low and medium growth scenarios expect the natural increase of 15,761 individuals in 2011 to become negative by 2023 and 2028, respectively. The high growth scenario forecasts an excess of births over deaths over the entire projections horizon (of at least 9,000 annually) – albeit with a decreasing trend in the second decade. Thus, natural population growth should decrease before 2031, even when fertility levels recover.

Figure 9. Evolution in the number of birth and deaths, natural increase and net-migration, Albania 2011-2031



It is therefore interesting to compare the trends in births with that implied by the zero-migration variant of the medium growth scenario. The difference provides useful information on the effect of the age-structure – or, to put it differently, on the effect of the future ageing of the younger (older) cohorts into (and out of) the childbearing ages. If borders would remain closed over the next 20 years, the number of births would actually increase even more until 2020 than implied by the high growth scenario – despite the lower level of fertility assumed. The cohorts born in the 1990s (aged 10 to 19 in 2011) are indeed more numerous than those born in the 1980s (because the latter have been depleted by past emigration; see section 4.3). These former would therefore have a higher total number of births when entering in their life-period of family formation in the 2010s. In the 2020s, however, the number of births would decline at a rapid pace when subsequent and less numerous cohorts born in the 2000s reach the main childbearing ages. Hence, the declining trend in the number of births observed (sooner or later) in all scenarios is driven by the irregular age structure of the Albanian population. More specifically, the number of births will decline as the population in the main childbearing ages shrinks after 2021. Continuous emigration and lower fertility rates should exacerbate this structural effect in limiting natural increase in the future.

Net international migration manifests the inverse trend to natural increase (right-hand side panel of Figure 9). Starting from a similar but negative level of -19,000 individuals in 2011, the trend is upward – although the extent and timing of this increase differs according to the scenario. The high growth scenario forecasts a sharp increase of net migration, which should however remain negative: from -19,000 in 2011 to -5,034 in 2020, followed by a further slight increase thereafter. The medium growth scenario predicts a slow increase to -15,714 in 2020, which intensifies in the second decade (reaching -6,965 individuals in 2031). The low growth scenario, by contrast, anticipates an initial decrease in net migration to -33,562 until 2021, followed by a strong recovery to -15,992 in 2030. This strong decline in migration balance during the first decade, despite an assumption of decreasing rates of emigration, can again be explained by structural effects: Compared to the second projections decade, larger cohorts will progressively enter into the peak ages of migration in the 2000s, leading to a higher total number of emigrants.

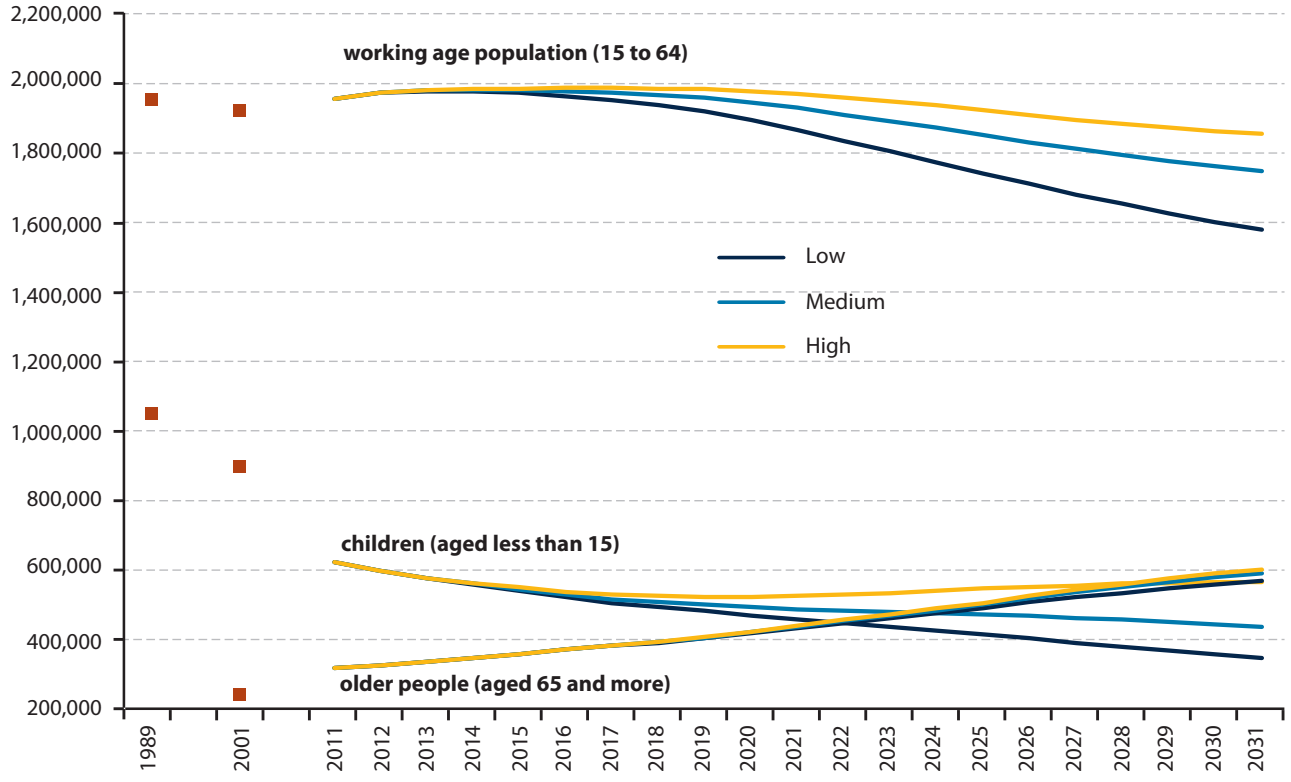
We can thus conclude that the Albanian population only slightly declines in the medium growth scenario because the drop in natural increase is to a large extent compensated for by an increase in net migration. Positive population growth in the high growth scenario, by contrast, results from the combined effect of a postponed and less marked drop in natural increase, which remains positive, and a trend towards a zero migration balance. Conversely, the pronounced demographic decline forecasted by the low growth scenario results from the sharper drop in natural increase, which is sustained by a more evident negative migration balance.

Population by age group

The future evolution of the Albanian population differs significantly according to the age groups. The number of older people aged 65 and more is projected to increase strongly, whereas the number of children aged less than 15 should continue to decline – although less strongly than over the past 20 years. The population of working age (15 to 64) should also decline.

Despite the large cohorts having reached working age over the last two decades, the population of working age remained relatively constant (above 1,920,000) because of the large scale emigration among young adults (Figure 10). If this stabilization should continue in the next ten years, a decline in the number of individuals aged 15 to 64 is expected in the 2020s. The medium growth scenario forecasts a decline of -11% to 1,753,129 by 2031. The high and low growth scenarios imply a drop of -5% and -19%, respectively (leading to 1,861,100 and 1,584,128 individuals in 2031). The working age population would only slightly increase (to 2,088,928) if borders remain closed.

Figure 10. Evolution in the number of population by age groups, 1989-2031



The number of children aged less than 15 should also decrease from 626,870 in 2011 to 437,701 in 2031 (i.e. by 30%) according to the medium growth scenario. The high growth scenario forecasts a 16%-decline to 526,443 in 2021, followed by a recovery to 567,224 in 2031. The low growth scenario, by contrast, predicts a continuous decline by 44% until 2031, leading to a total of 349,177 children.

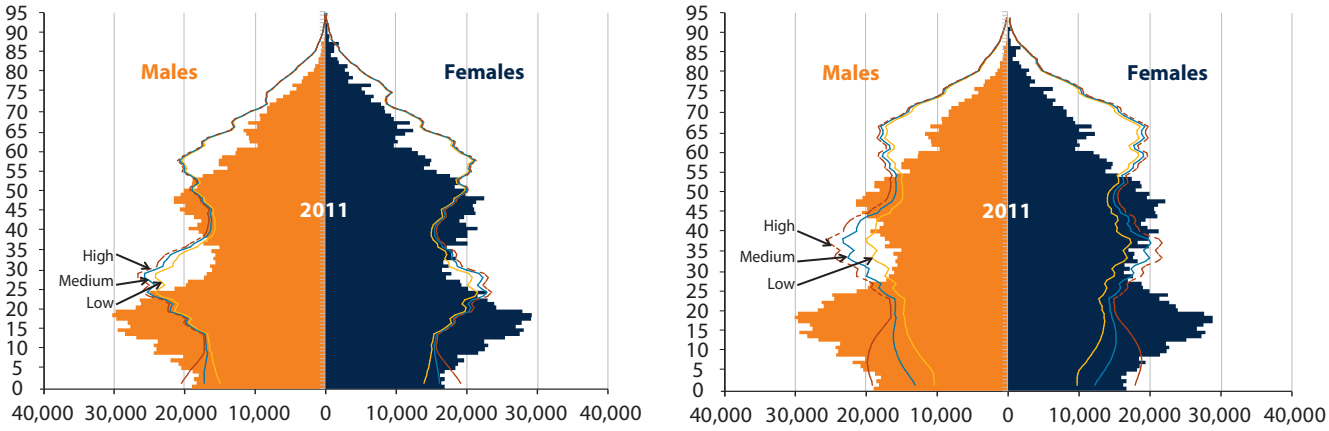
The number of older people aged 65 and more, by contrast, increases by 84%, relative to 2011, to reach between 570,445 and 604,693 individuals in 2031. This is explained by the attainment of retirement age by the baby boom generations (born between 1945 and 1960). They are not only more numerous than the previous generations due to the high fertility level and the fast decline in (infant) mortality at time of birth, but were also less depleted by emigration since 1990 compared to the younger generations. The number of very old people (aged 80 and more) is expected to more than double according to all scenarios, reaching more than 120,000 in 2031.

Age structure

The ageing of successive birth cohorts and the demographic events they experience over time will transform the age structure of the Albanian population. As shown in Figure 11, the age and sex pyramid will widen at the top as the numerous baby-boom generations enter into retirement age. Moreover, the ageing of the cohorts born in the 1990s (aged between 10 and 20 years in 2011) will increase the number of adults in the main childbearing ages in 2021 (see left-hand side of Figure 11). Ten years later, however, these cohorts will be replaced by the subsequent birth generations, which are considerably less numerous, leading to a decreasing number of adults in childbearing age (right-hand side panel).

Moreover, men should outweigh women at the ages 20 to 44 in 2031, despite their higher mortality and the assumption of equal emigration rates for both sexes. All three scenarios indeed expect more than 110 men for 100 women. This sex-imbalance is the consequence of the rising sex-ratio at birth since 1989. Thus, a shortage of women at ages concerned with marriage can be expected in the future, limiting the prospects for a significant share of men to found a family.

Figure 11. Age and sex pyramid in 2011, 2021 and 2031, Albanian population

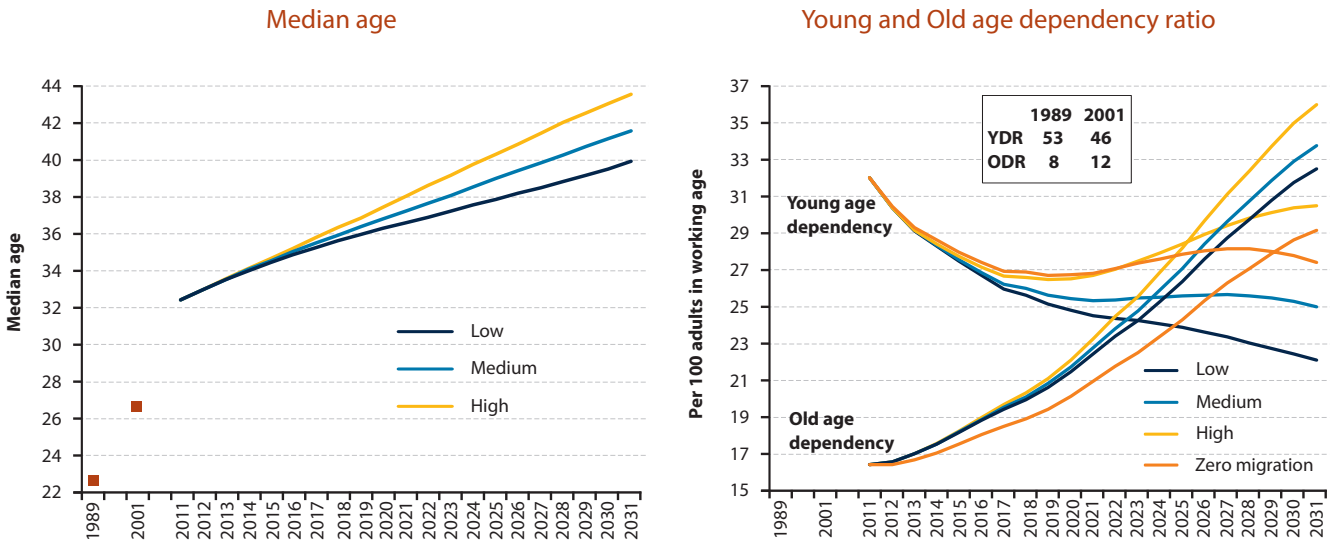


Negative net migration in the future should mainly deplete the cohorts aged between 10 and 25 in 2011.This emigration of couples in reproductive age, combined with the lower fertility rates assumed in the low and medium growth scenario, leads to a lower number of children and thus intensifies the shrinkage of the base of the population pyramid. The high growth scenario, by contrast, projects a wider base due to the assumption of lower emigration and higher fertility, which increases the total number of births.

Population ageing in Albania

The different trends in the population by age groups imply a demographic process of ageing. The median age (i.e. at which half of the population is younger and the other half older) is forecasted to increase continuously – although to a lesser extent when compared to the recent past (Figure 12): it should reach 41.7 years in 2031 according to the median growth scenario, with a range of 40.0 and 43.6 years according to the high and low scenario (up from 32.6 in 2011). Albania should have caught up to the current median age in Europe by the end of the projections horizon.

Figure 12. Evolution in median age of population and in the young and old age dependency ratio, Albania 1989-2031

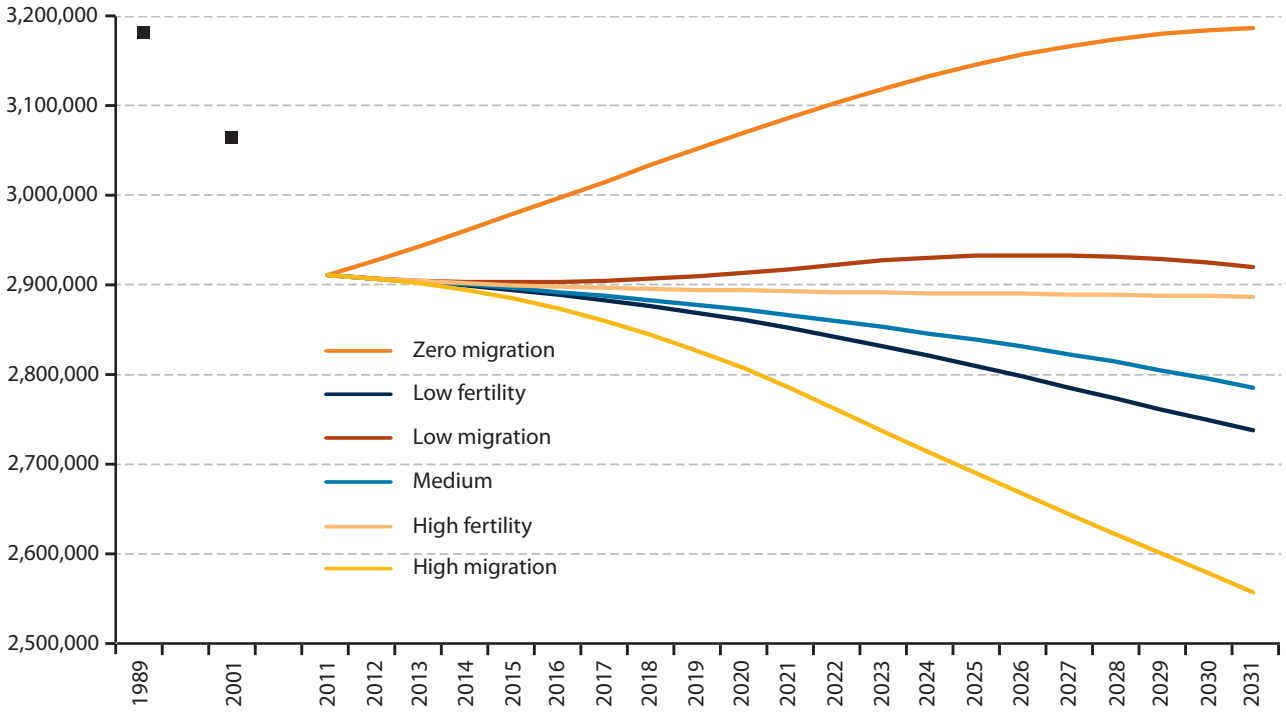


Albania's population will not only grow older, but the patterns of ageing are also forecasted to transform in the future. Until 2011, ageing was mainly driven by shrinking birth cohorts – i.e. ageing at the base of the pyramid: The young age dependency ratio indeed dropped from 53 children per 100 adults of working age in 1989 to 32 in 2011. Old age dependency has been limited so far, although it doubled from 8 to 16 individuals per 100 adults of working age. Young age dependency is forecasted to decline at a similar rate when compared to the rise of old age dependency until 2021(down to 25 children and up to 23 elderly per 100 adults of working age, respectively, according to the medium growth scenario). In the second projections decade, the trend in young age dependency depends on the scenario with a tendency of stabilization or slight decline. The high growth scenario implies a recovery due to the assumptions of high fertility and smaller migratory losses. The rising trend in old age dependency, by contrast, should intensify when the baby boom generations start reaching retirement age in the 2020s. The medium growth scenario implies 30 older people per hundred adults of working age in 2031. If advanced ageing is defined as the proportion of older people, relative to the working age population, exceeding that of children, its onset can be expected before 2025 in Albania.

ASSESSMENT OF THE SENSITIVITY OF THE PROJECTIONS TO THE HYPOTHESES

To analyse the sensitivity of the projections results to the assumed trends in fertility, migration and mortality, we compare the medium growth scenario with its analytical variants which differ by a lower or higher hypothesis for either migration or fertility. This exercise also aims at identifying the main demographic factors of future population change in Albania: The larger the differences in the results implied by these variants, compared to the medium (reference) scenario, the more determinant for Albania's demographic future is the trend in the demographic component for which another hypothesis was substituted. The Figure 13 compares the forecasts of total population according to the medium growth scenario, as well as its variants (as the differences in the assumptions of mortality have a minor impact on the overall population, these variants are not shown).

Figure 13. Evolution in the number of population according to the medium growth scenario and its variants, Albania 1989-2031



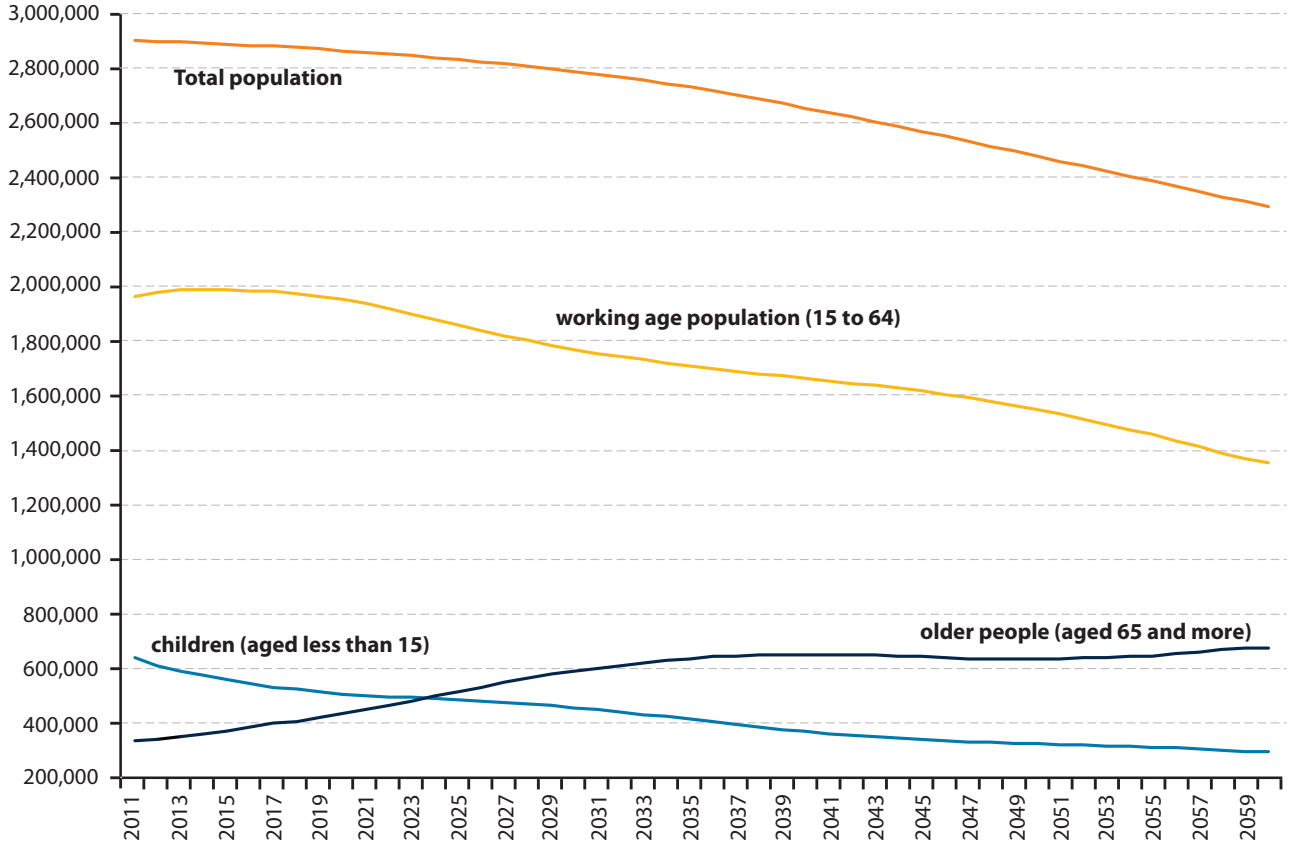
Results confirm a major role in future demographic change for migratory behaviour and the age structure when compared to trends in fertility (and mortality). The variants assuming a low or high emigration forecast respectively a total population of 2,917,012 or 2,552,504 in 2031– implying a difference of +4.8% or -8.3% relative to the medium growth scenario. The difference is greatest in the zero-migration variant (+14.5% in 2031), because the cohorts of working age are less depleted and have a higher total number of children, compared to the medium reference scenario.

The variants assuming low or high fertility imply a total population of 2,734,755 or 2,883,143 in 2031, which represents a minor difference with the medium reference scenario of -1.7% and +3.6%, respectively. Thus, the national projections are most sensitive to the assumptions on international migratory behaviour because of the high rates at baseline. In the same time, Albania's future demographic trajectory will be significantly determined by the effects of the irregular age-structure as observed in 2011. The ageing into the main ages of childbearing and migration of the relatively large cohorts born in the 1990s will inflate the assumed behavioural trends in terms of number of demographic events (births and emigrants) in the 2010s and 2020s, respectively. Changes in fertility behaviour will have a smaller demographic impact, and the future evolution in mortality only marginally affect population trends because Albania's population is still relatively young.

THE MEDIUM GROWTH SCENARIO EXTENDED UNTIL 2060

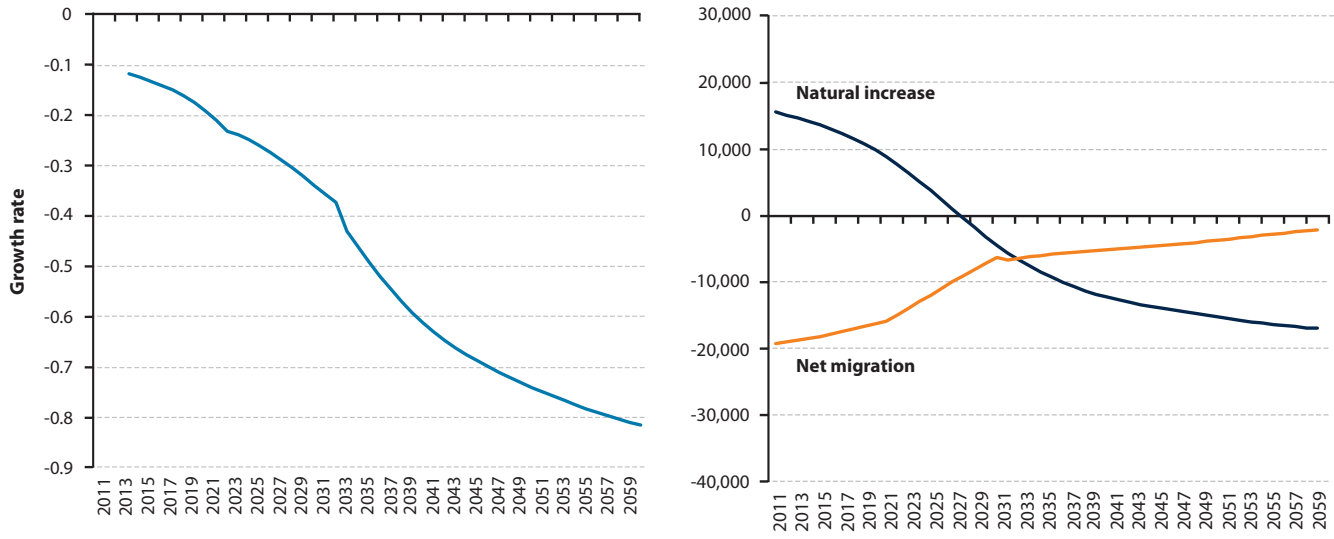
Given Albania's dynamic demographic context, the extension of any projections beyond the horizon of 20 years is a hazardous exercise. The medium growth scenario until 2060 must therefore be taken with caution and interpreted as a rough indication of a possible trend. The projections results imply an intensification of demographic decline after 2031 to reach 2.3 million residents in 2060 (Figure 14). The working age population should also decline to reach less than 1.4 million because of structural effects: the larger cohorts born through the 1990s will reach retirement age and will be replaced by considerably smaller cohorts attaining working age. The population of children is expected to continuously decline under 300,000 in 2060, whereas the number of older people should stabilize above 600,000 from 2040 on.

Figure 14. Evolution of the number of total, working age population, children and older people, Albania 2011-2060



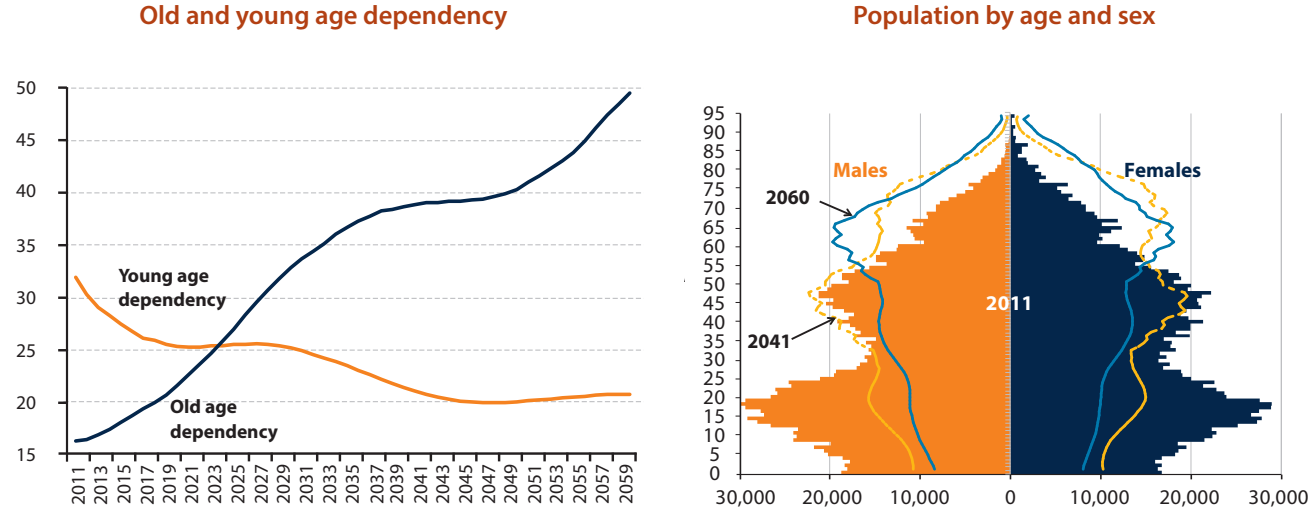
The rate of population decline is expected to drop at a fast pace to reach 0.8% in 2060 (Figure 15) – similarly to the rate observed in the 2000s. The reason for this acceleration of depopulation lies in the fact that natural growth should become strongly negative (-17,000 individuals in 2060). The negative level of net migration is expected to become insignificant in 2031 (despite the assumption of constant rates of emigration from 2031 on) due to lower number of emigrants implied by a shrinking population of young adults.

Figure 15. Growth rate and number of natural increase and net migration, Albania 2011-2060



Demographic ageing should progress at a fast pace, particularly in the 2020s and the 2050s when the baby-boom generation (aged 45-64 in 2011) and today's young adults reach retirement ages, respectively (Figure 16). One older person may have to be supported by only two working age individuals in 2060. Conversely, the young age dependency ratio is expected to decline to two children per 10 adults of working age.

Figure 16. Old and young age dependency and the population structure by age and sex, Albania 2011-2060



Thus, Albania's population pyramid will transform into a bell-shaped structure with a very narrow base in the future (Figure 16). The majority of residents should be aged 50 years and more in 2060.

POPULATION PROJECTIONS AT PREFECTURE LEVEL

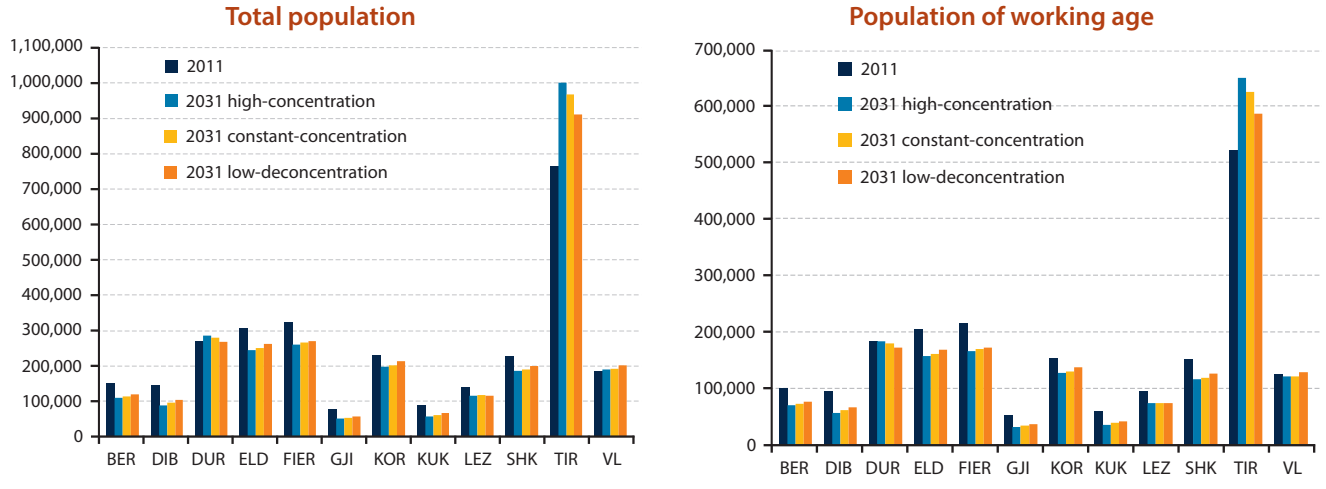
According to the regionalized medium growth scenarios for 2031, the majority of prefectures will lose population – except Tirana, Durrës and Vlorë (Figure 17).

The number of inhabitants in Tirana prefecture is forecasted to increase by less than a fifth from 763,560 in 2011 to 909,252 in 2031, according the low internal migration scenario which also assumes a redirection of migrants to other centres of Albania. Assuming a rising and geographically focussed internal mobility (the high scenario) would lead the population of Tirana prefecture to increase by less than a third to reach almost 1 million residents (the urban agglomeration of Tirana is actually larger, as it extends into Durrës and Elbasan prefecture). The medium internal migration scenario (which assumes a constant level and spatial structure of migration) is not far from this threshold (951,338 residents in 2031). The increase in population over the next two decades should be much more limited in Vlorë (between 3% and 12%) and Durrës (by maximum 7%).

The strongest depopulation is projected for Dibër and Kukës in the North (-30% or more until 2031, according to the medium internal migration scenario), as well as for Gjirokastër and, to a lesser extent, Berat in the South (at least -20%). The remaining prefectures should experience a decline in the number of residents ranging between 10% and 20% in the next twenty years.

One has to recall that all these internal migration scenarios are based on the same regionalized medium growth scenario defined at the national level, which assumes a smooth decline in both fertility and emigration until 2031. In the case of a faster decline or even a trend reversal – such as assumed in the low and high growth scenario at the national level, the prefectural populations in 2031 may be 9% lower or higher, respectively, when compared to the results in Figure 17. This range in uncertainty is larger than the relative differences between the internal migration scenarios. Since emigration is higher than out-migration in the majority of prefectures, this demographic component should indeed be more important for the demographic future of Albania's prefectures.

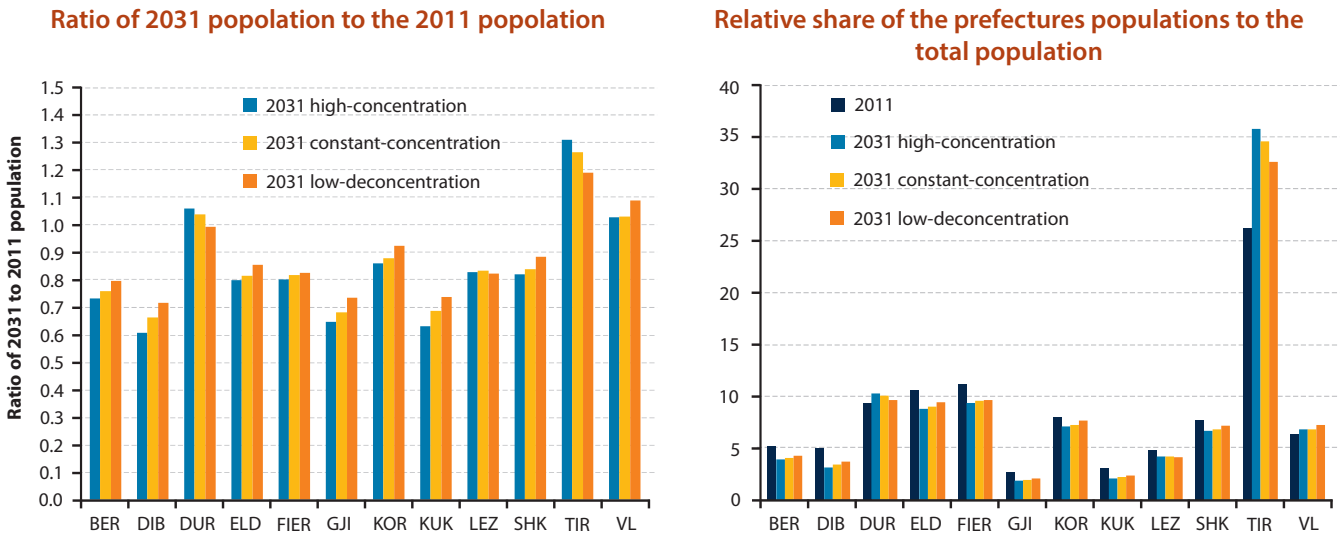
Figure 17. Evolution of total and working age (aged 15-64) population according to three scenarios of internal migration, Prefectures of Albania, 2011-2031



Note: Regionalized medium growth scenarios with different levels of internal out-migration and different degrees of spatial concentration of in-migrants.

The working age population should decline at a slightly faster pace than the total population: by more than 18% in almost all prefectures (Figure 17), except those gaining population through migration (Tirana, Vlorë and Durrës). Tirana is the only prefecture which should experience a significant increase in the potential labour force (by 20% by 2031, according to the medium scenario with constant out-migration and geographic distribution). The strongest decline in the potential labour force is forecasted for Gjirokastër (by -43%), as well as for Berat and Dibër (by at least -30%). If the level of internal migration increases alongside the decline in emigration, and if there is a diversification of domestic destinations, the labour force should shrink to a lesser extent – especially in those prefectures where an increasing attractiveness for migrants was assumed (Korçë, Gjirokastër, Elbasan, Berat, but also Lezhë; see summary Tables and population pyramids in the Appendixes).

Figure 18. Ratio of 2031 to 2011 population and evolution in population shares relative to the national total according to three scenarios of internal migration, Prefecture of Albania, 2011-2031

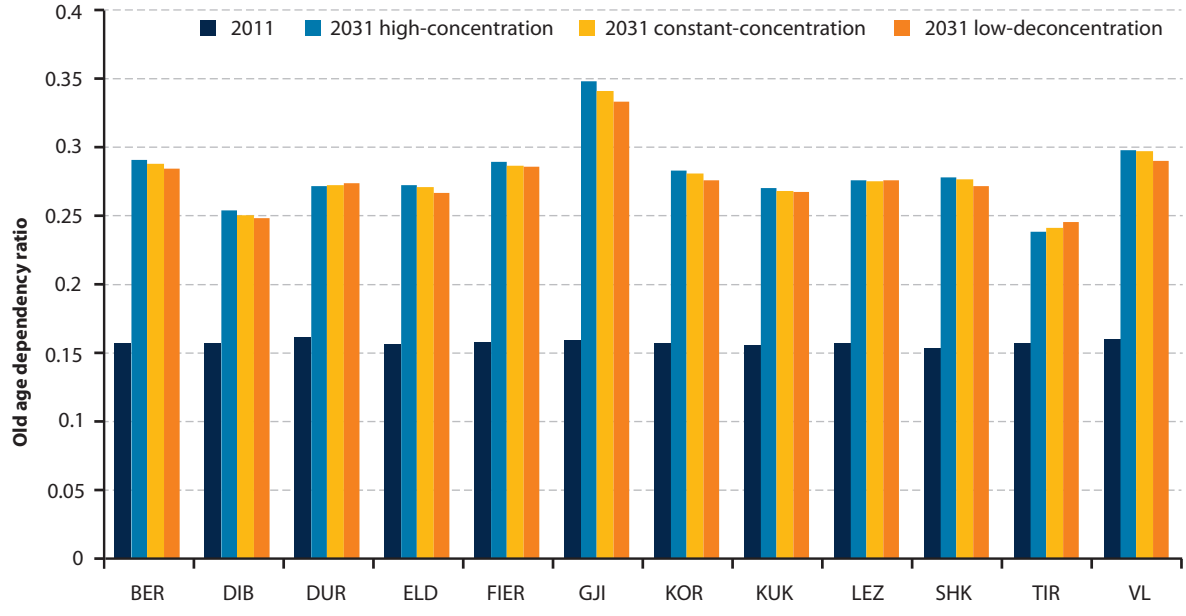


Note: Regionalized medium growth scenarios with different levels of internal out-migration and different degrees of spatial concentration of in-migrants.

These trends will exacerbate the spatial concentration of Albanian population in the future. The share of total population living in Tirana prefecture is forecasted to rise from 26% in 2011 to 35% according to the medium internal migration scenario (Figure 18).

Demographic ageing will progress more rapidly in the South, with small differences between the scenarios (Figure 19). In 2031, there should be almost 30 inhabitants aged 65 and over per 100 individuals of working age in Berat, Korçë and Vlorë. In Gjirokastër the ratio should increase to 34, representing twice the current level. Old age dependency will remain lowest in Kukës and Dibër because of the smaller retirement cohorts in the future and the high fertility until recently. The demographic dependency of older people should also remain limited in Tirana, Durrës and Elbasan, where the working age population is forecasted to be continuously swollen by in-migration from other places in Albania and abroad.

Figure 19. Old age dependency ratio according to three scenarios of internal migration, Prefecture of Albania, 2011-2031, in (%)



Note: Regionalized medium growth scenarios with different levels of internal out-migration and different degrees of spatial concentration of in-migrants.

The projections for each prefecture are summarized in the Tables and Pyramids shown in the Appendixes. These highlight several transformations in regional demographic dynamics. Since the same ratio of decline in emigration was assumed across all prefectures, the levels tend to converge. Although until recently, demographic growth resulted to a significant extent from natural increase in all prefectures, this should change however in the future.

The majority of prefectures should experience a decline in the number of births. Combined with an increase in deaths throughout Albania, they should experience a natural population decline in the future. Tirana is the only prefecture were natural increase remains positive because of a more favourable age structure related to the strong in-migration of mainly young women who swell the cohorts of childbearing age (thereby increasing the number of births and decreasing the proportion of deaths relative the total population). Yet in the case of Durrës, the spatial structure of in-migration must remain focussed on the Tirana-Durrës area in the future for internal net migration to sustain indirectly natural population growth.

Kukës and Dibër (and, to a lesser extent, Shkodër) are other exceptions because of the historically lagged fertility decline. Gjirokastër, by contrast, should experience the strongest natural population decline (-0.5% in 2031), reflecting its early onset of fertility transition combined with a massive emigration and out-migration from this prefecture until recently. Thus, if the national level of fertility declines as slowly as anticipated in the medium growth scenario, and prefectures continue to trend in a similar way, population mobility would become the main determinant of demographic growth throughout Albania in the future.

Five different types of demographic regimes can be distinguished across the 12 prefectures. In Tirana, Vlorë and Durrës, population stabilization or growth is expected to be driven mainly by positive net internal migration, as well as by international return migration in the case of Vlorë.

A second group is constituted by Kukës and Dibër, which despite a balance excess of births over deaths should experience a strong population decline due to a strongly negative internal migration balance that represents at least three times the negative net international migration, according to the medium internal migration scenario. However, if the level of out-migration declines, demographic losses will result as much from internal as from international departures.

Berat and Fier form a third group. Despite a negative level of natural increase, the sustained population losses in these prefectures should be mainly due to both internal and international migrations (the dominance of one over the other depends on the assumption on the level and spatial focus of internal migration).

The fourth group includes Korçë and Gjirokastër, which can be distinguished based on the equal importance of negative natural increase and negative net internal and international migrations in the demographic decline.

Lezhë, Elbasan and Shkodër form the last group characterized by a trend towards a balanced number of births and deaths. Demographic decline until 2031 is mainly driven by international migration (unless internal migration increases in the future).

To sum up, a decline in international emigration rates to one third of the level observed in the 1990s by 2031 in all prefectures, combined with a smooth reduction in fertility, implies a depopulation of up to 40% in most prefectures (but Tirana, Vlorë and Durrës). Internal migration will play a minor role in population dynamics in the future because its level is considerably lower when compared to international migration. Given the strong spatial focus of internal movements, these should however significantly determine the demographic trends in the main regions of origin and of destinations: Kukës, Dibër, Tirana, Durrës and Vlorë.

5

Conclusions

Albania experienced pronounced demographic changes over the last twenty years. Having been characterized by the highest population growth in Europe during the post-war period, the country has shifted to population decline since 1990. More than a million Albanians moved to foreign countries, particularly from peripheral areas. Alongside sustained internal migration, this led to a spatial concentration of population in and around the main urban centres. Though this population redistribution was initially driven by the post-communist crisis, internal and international migration was increasingly motivated by family reasons and opportunity-seeking strategies in the last decade, and concerned mainly young adults and more and more women. Combined with the sharp reduction of fertility levels in Albania, this intensified the fall in the number of births, thereby reducing the weight of children in the total population. In the same time, the share of older people increased because numerous cohorts born in the early communist period are currently reaching retirement age, leading to a fast process of population ageing.

These recent demographic trends will continue in the future. Albania's population trends will be determined mainly by migratory and fertility behaviours. Their demographic effects will be amplified during the 2010s by the entering of relatively large cohorts of young people in the main ages of migration and childbearing. According to the different scenarios of population growth, the number of residents should range between 2,782,310 and 3,033,017 in 2031, which represents respectively a loss of 14% and a slight increase of 4% relative to the population of 1st January 2011. Although the population of working age should stabilize in the next ten years (i.e. above 1,920,000 individuals), it is expected to decline by up to 11% by 2031. In the absence of international migration, by contrast, this potential labour force would slightly increase above two million.

The demographic context in Albania is expected to transform in the future. Because of the ageing of the baby-boom generations, the number of deaths will increase by less than half, while the number of births should decrease when smaller cohorts born in the 2000s will enter into the main childbearing ages – unless fertility rates increases in the future. The annual number of deaths is expected to be higher than the number of births by 2031. However, if young generations continue to emigrate and further decrease their fertility, Albania will experience natural population decline as soon as in the early 2020s. Moreover, the high sex ratio at birth since the 1990s will lead to a growing sex-imbalance in the future population of childbearing age, which may limit the prospect of a significant share of men to found a family.

The decrease in natural population growth will be only partially compensated for, by smaller demographic losses from international migration in the future. As the incentives to move abroad should decrease alongside the development of Albania, the rate of emigration is expected to fall. Yet because the population in the peak ages of emigration will increase in the next ten years, the number of emigrants should nevertheless exceed between 5,000 and 16,000 the number of immigrants in 2021. This should be followed by a faster decline in the number of emigrants, leading to an almost neutral migration balance by 2030. Depending on Albania's economic performance relative to other European countries, which may determine its capacity to provide attractive opportunities in the labour market for young residents and potential returnees, the projections imply a range of 100,000 to 300,000 more emigrants than immigrants over the next twenty years.

The main consequence of the expectations of low fertility and the continuing (although lower) emigration in the future is the transformation of Albania's population age structure. The child population should continue to drop (by a fourth) and that of older people should increase by more than four fifth by 2031. This will lead to a catching-up to the advanced population ageing currently observed in Europe, with more dependents at older ages when compared to children. This transformation from a dominant young to old age demographic dependency may last only one generation in Albania, compared to half a century in Western Europe.

Recent demographic trends are also anticipated to continue at the prefectural level. Population increase until 2031 can only be expected for Tirana (up to 30%) and, to a lesser extent, Vlorë and Durrës because these prefectures constitute the primary destinations of internal and international immigration. Tirana is the only prefecture in which the working age population can be expected to increase. The sharpest drop in the number of residents by 2031 is projected for Northern and Southern prefectures (up to -30%).

Natural population decrease should concern most prefectures in the future, except those having experienced a more recent onset of fertility decline (as in the North) and the economic centres which absorb the majority of the young internal migrants who are expected to bear their children at that destination. Population ageing will progress more rapidly in the South because of its early onset of fertility transition and the large-scale emigration since 1990. These regional demographic dynamics will accentuate the geographic concentration of Albania's population in the main economic centres of the country, most notably Tirana. According to the medium growth scenario, 45% of population is expected to reside in Tirana and Durrës prefectures in 2031 (up from 35 % in 2011).

The detailed results of the different projections scenarios at the national level can be found in the Appendixes. At the national level, the low growth scenario provides a plausible minimum forecast because it foresees a fast decline in

fertility and a slow decrease in emigration in the future. The high growth scenario represents the upper range of forecasts because fertility is expected to recover from the current low levels and emigration to decline at a faster pace. The medium growth scenario assumes an intermediate trend in these components of demographic change and provides a medium forecast. The detailed results at the prefectural level in the Appendixes refer to this medium growth scenario which was regionalized by prefecture assuming additionally a constant level of out-migration and a constant spatial focus of in-migrants. These results must however be used with caution, as alternative trends in emigration (than assumed in the medium scenario) would lead to important differences of population at the prefectural level.

6

Appendixes

APPENDIX 1: GLOSSARY AND METHODS

Glossary

Age-specific fertility rate	Relate the number of births to women of a particular age group, in a specific calendar year, to the mid-year population of women in that same age group
Child mortality	Probability of dying between birth and exact age 5, per 1,000 births
Cohort	A group of people sharing a common temporal demographic experience who are observed through time. The birth cohort (also called generation) of 1900 is the people born in that year.
Crude birth rate (CBR)	The ratio of the number of live births in a year divided by the total population of that year. This coefficient is frequently expressed per 1,000 inhabitants.
Crude death rate (CDR)	The ratio of the number of deaths in a year divided by the total population of that year. This coefficient is frequently expressed per 1,000 inhabitants.
Emigration	A departure from the national territory for at least 12 months
Gross migraproduction rate (GMR)	The average number of migrations a hypothetical cohort of individuals would experience until the end of their life period if they were subject during their whole lives to the migration rates of a given period (and if they were not subject to mortality). It is expressed as migrations per individual.
Life expectancy at birth (E0)	The average number of years of life expected by a hypothetical cohort of individuals who would be subject during all their lives to the mortality rates of a given period. It is expressed in years.
Median age	The age at which half of the population is younger and the other half older
Out-migration	A move out of a sub-area of a given country to another sub-area of the same country
Immigration	An arrival in the national territory for at least 12 months
Infant mortality	Probability of dying between birth and exact age 1, per 1,000 births
In-migration	A move in a sub-area of a given country from another sub-area of the same country
Net migration	Net number of migrants, that is, the number of immigrants minus the number of emigrants.
Net migration rate (NM)	The net effect of immigration and emigration over the population of a territory, expressed as an increase or a decrease per 100 inhabitants of that territory, in a given year.
Rate of natural increase (NI)	It is the coefficient with which a population increases (or decreases) in a given year as a result of the difference between the number of births and deaths, expressed as a percentage of the total population.
Sex ratio	The number of men per 100 women in population
Sex ratio at birth	The number of male births per 100 female births
Total fertility rate (TFR)	The average number of children a hypothetical cohort of women would have at the end of their reproductive period if they were subject during their whole lives to the fertility rates of a given period (and if they were not subject to mortality). It is expressed as children per woman.
Old age dependency ratio (ODR)	The ratio of the number of older people (aged 65 and more) to the population of working age (15-64)
Young age dependency ratio (YDR)	The ratio of the number of children (aged less than 15) to the population of working age (15-64)

Methods

*Estimates of **intercensal emigration rates**, using the life-table survival method based on Census 1989, 2001 and 2011:*

Sex and age-specific cohorts enumerated in the first census, as well as the annual number of births in the intercensus interval, were forward-survived to the date of the second census (yielding an estimate of a hypothetical closed population) and compared with the observed population at the second Census (in 2011, we only considered the population who resided in Albania in 2001); the residual is an estimate of the emigrant stock. We then estimated intercensus emigration transition rates (net of mortality) in dividing the stock by the closed population in 2011; the rates were annualized and assigned to the age attained by each cohort in the middle of its exposure period. The empirical age-specific rate schedule was then smoothed using a multiexponential function in the Excel program elaborated by (Wilson 2010).

Similarly to the TFR, a summary measure of the intensity of emigration was obtained – the gross-migraproduction rate (GMR; Rogers and Castro 1980) – in summing the (smoothed) age-specific rates. This measure can be interpreted as the number of emigrations an individual can expect to experience if he would subject during all his life to the migration rates observed in the reference period. To facilitate comparisons, the age-specific rate schedules shown in Figure 6 were scaled to a GMR of unity (i.e. normalized according to the level of migration).

*Estimates of **intercensal emigration from prefectures**, based on the 2011 Census :*

The underlying five-year transition rates (net of mortality) were estimated by the life-table survival method from the 2001 and 2011 Census as outlined above, with the notable difference that the migrant stock was obtained as the residual between the forward-projected closed prefectural populations and the observed population of Albania in 2011, which was redistributed according to prefecture of residence in 2001. The enumerated children born during the intercensal interval were redistributed according to prefecture of birth. The 10-year migration rates (referring to 5-year age groups in the middle of the intercensal interval) were transformed into 5-year migration rates.

*Estimates of **inter-prefectural out-migration rates**, based on the 2011 Census.*

Five-year transition rates of inter-prefectural migration (net of mortality and emigration) were obtained from the Census 2011 by dividing the number of enumerated out-migrants by the total prefecture populations (redistributed according to place of residence in 2006).

*The **life table** for 2011:*

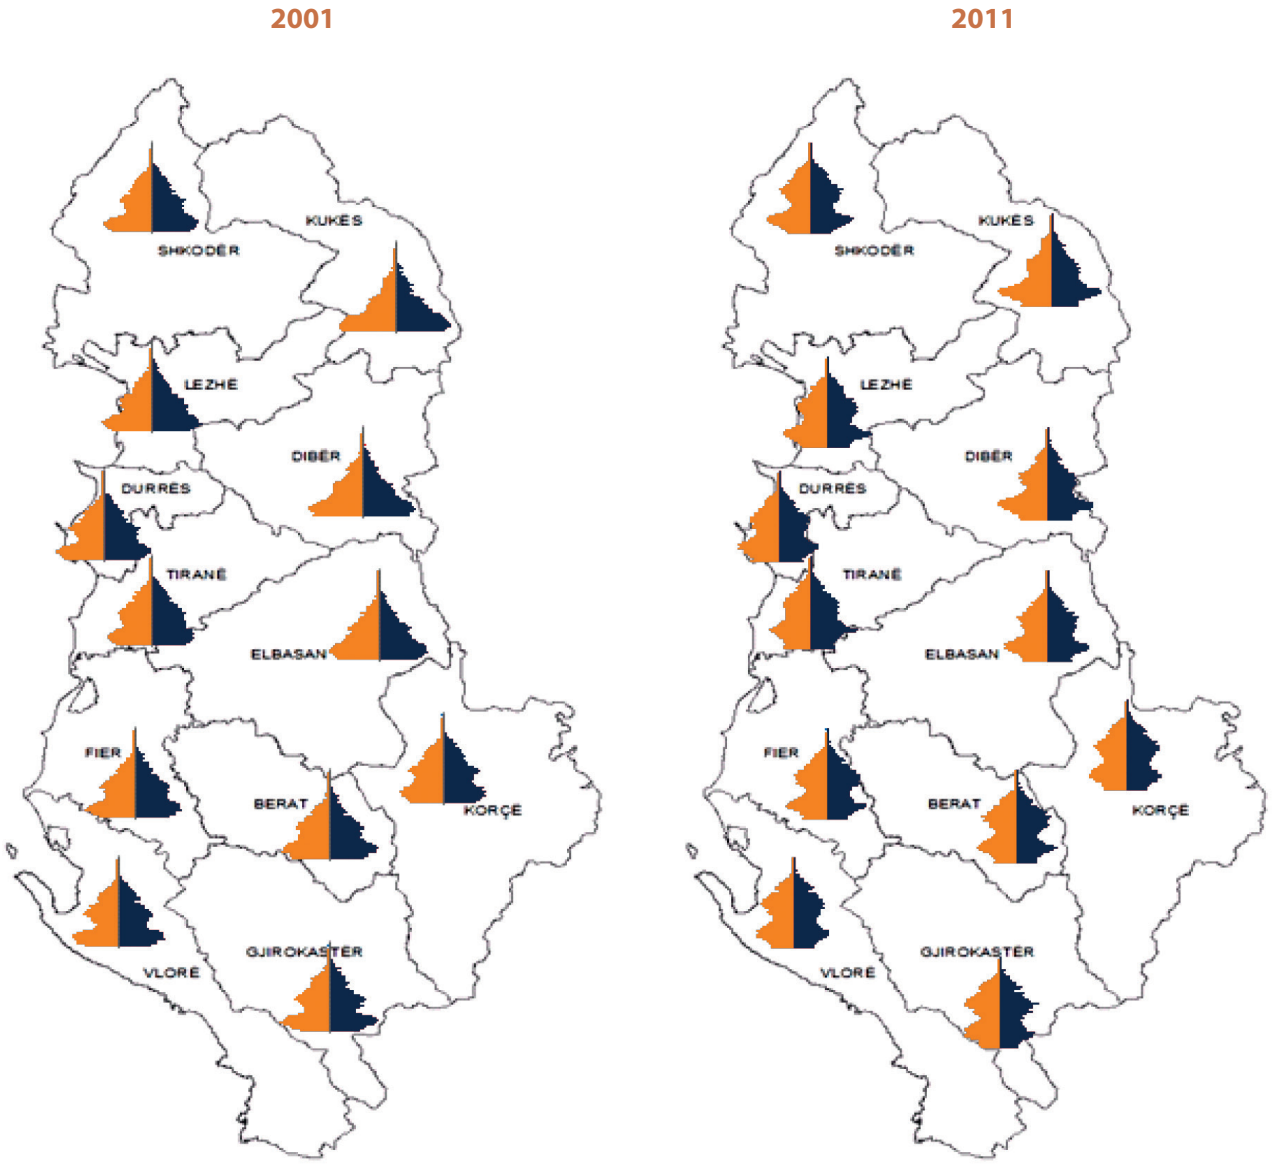
We combined the DHS estimate of infant and child mortality referring to 2008, redistributed the level by sex according to the sex-ratio of mortality observed from vital statistics, and reduced the rates to reflect the improvements until 2011 observed from vital statistics. These mortality rates for children were then combined with rates at older ages, which are based on the annual number of registered deaths in the period of 2010-2012 and the Census 2011 population.

APPENDIX 2: DEMOGRAPHIC CHANGE IN ALBANIA'S PREFECTURE (DETAILED ANALYSIS)

Population decline since 2001 concerned all prefectures except Durrës and Tirana, where the number of residents increased respectively by an annual rate of 0.3% and 1%, because of lower emigration and higher internal in-migration (see Appendix Table 1). The rate of demographic decline was at least 1% annually in the South (especially in Gjirokastër and Berat, due to internal and external migration), and in the North (Kukës and Dibër, having experienced high rates of internal departures).

The most irregular shapes of the age and sex pyramid were observed in Gjirokastër, Shkodër, and Lezhë (see Figure 20). The population structure in Tirana and Durrës evinces comparatively less indentations because the emigration of young adults was lower and was compensated for by internal in-migration. Tirana and Shkodra are the only prefectures where women are more numerous than men in 2011, reflecting the lower level of emigration and the high level of in-migration of mainly women from other Albanian regions.

Figure 20. Pyramid of population (in %), Albanian prefectures 2001 and 2011



Geographic differentials in young and old age dependency not only reflect differences in age-selective emigration, but also in the historical onset of fertility decline. The South initiated the trend in the 1960s and is consequently characterized by the highest old age dependency and the lowest young age dependency ratio (i.e. above 30 older people and under 30 children per 100 individuals of working age; Appendix Table 1) – especially in Gjirokastër, Korçë, Vlorë and Berat. These prefectures shifted rapidly from a dominant young to old age dependency. In the North of Albania, young age dependency ratio peaks at more than 40% in Dibër and Kukës, which testifies to the recent completion of the first demographic transition.

Given the low level of mortality at adult ages, its geography is mainly determined by differences in infant- and child-mortality. Although the rate declined sharply over the last forty years, spatial differentials remained unchanged (see Gjonça 2001; Lerch et al 2010). Indirect estimates from the last Census for 2008 confirm a higher child mortality in the North, with rates close to or above 30 deaths per 1,000 live births. In the South and the prefectures of Tirana and Durrës, there were less than 20 deaths (Appendix Table 1).

Since 1989, Albania experienced a regional convergence in fertility rates with sharper declines in remote and peripheral regions (by about 1 child during the 1990s). The prefectures' TFRs were all closely above replacement levels in 2001 (except in Kukës and Dibër, where the level was close to 3 children; Lerch et al. 2010). The convergence continued in the last decade, as evinced by vital statistics and the indirect estimations from the 2011 Census (using the own children method; Table 2). If Kukës and Dibër continued to catch up the trend (with a drop of at least one child), the decline was similar in all other prefectures (slightly less than half a child). Period fertility reached low levels that do not ensure anymore the demographic replacement of current generations in the future in all prefectures. The TFR ranges between 1.6 in Gjirokastër and 2.1 in Dibër.

Appendix Table 1: Demographic indicators for Albanian prefectures, 2001-2011

Indicator	Details	Reference period	Prefecture											
			BE	DI	DU	ELB	FI	GJ	KOR	KUK	LE	SHK	TIR	VL

Sources: Census 2001 and 2011, vital statistics.

The differences in fertility estimates from vital statistics and the Census in 2011 are small compared to 2000-01, confirming the improvements in measurement. Vital statistics consistently indicate a slightly higher level, except in Tirana and Shkodër, where it underestimates fertility by 0.3 children compared to Census estimates. According to the Census, fertility indeed declined the least in Tirana prefecture since 2001, which is in line with the trend during the 1990s (Lerch et al. 2010). This can be explained by the high level of in-migration of women or young couples to form their family in the social and economic centre of Albania (Lerch 2013). However, these women may register their births in the prefecture where they retained legal residence – which may explain the difference with the Census figures based on current residence. A similar pattern may explain the divergence in Shkodër. Thus, internal migration impacts on regional fertility levels in Albania. For the prefectural projections, indirect estimates of fertility were therefore used for Tirana and Shkodër.

Table 2 also reports the levels of international and internal emigration from the prefectures for the period 2007-11, which have been estimated indirectly from the 2001 and 2011 Census (see Methods in Appendixes). To ensure comparability, standardized indicators of the risk of emigration (referring to a 5-year period) are shown: the gross-migraproduction rate indicates the number of emigrations an individual can expect if current age-specific rates remain constant in the future.

International departures clearly dominate out-migration in all prefectures, except in Kukës and Dibër. If internal migration was very high since 1989 from these mountainous and peripheral regions, levels of emigration also recently increased which confirms the spatial diffusion of emigration opportunities throughout Albania. Yet the geography of international departures did not substantially change since 2001. The level remained highest in the South and on the coast (GMR is above 1.5 in Gjirokastër, Berat, Lezhë and Fier) and lowest in the main origin and destination regions of internal movements (the Northern prefectures of Kukës and Dibër, and Durrës and Tirana, respectively). Moreover, the age profile of migration is relatively similar across prefectures, and men and women emigrated to the same extent. This testifies to the recent transformation of Albanian migration patterns into a family-dominated phenomenon.

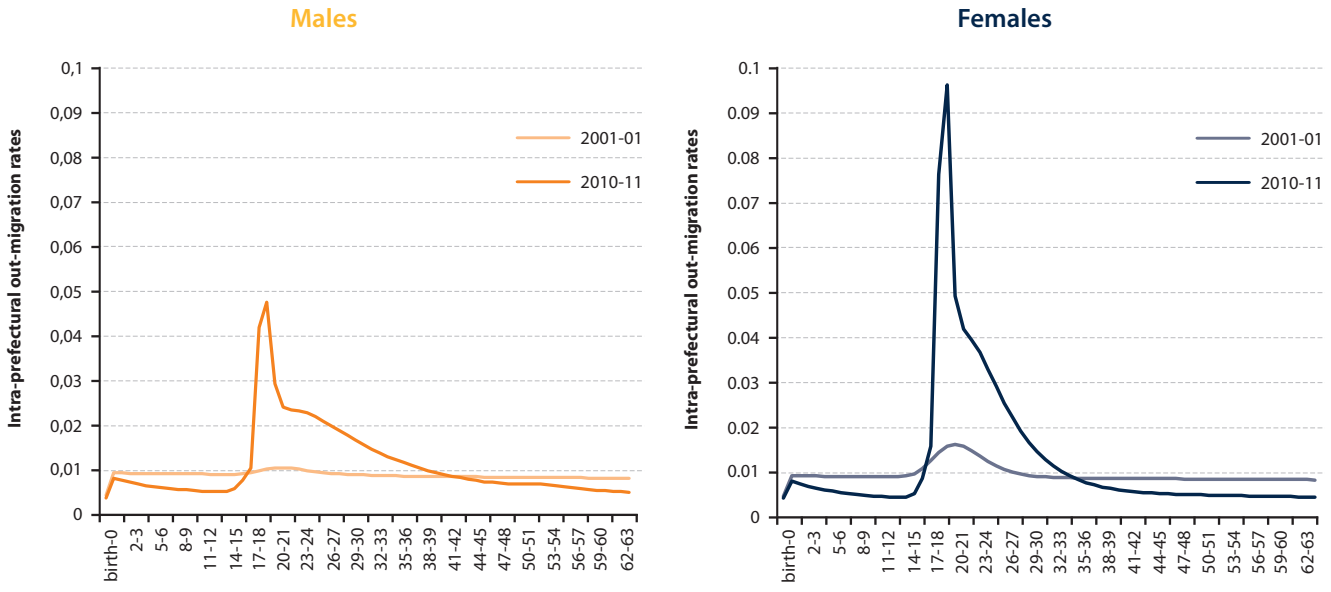
According to the last Census, recent returnees from abroad (2009-2011) mainly moved to more urbanized prefectures – such as Tirana (where 21% of male returnees settled), Durrës (8%), Elbasan (11%), Korçë (9%) –and to prefectures located along the Adriatic coast, mainly Vlorë (11%) and Fier (14%).

As with fertility, there has been a geographic convergence in the levels of internal out-migration, with most prefectures evincing a migraproduction rate between 0.4 and 0.8 in 2007-11. Dibër and Kukës evinced the highest rates of out-migration (with a GMR of at least 1.2) – although these levels were even higher in 2000-01. Moreover, out-migration was also high in Berat and Gjirokastër, which during the 1990s mainly experienced population losses to foreign destinations. Greek return migrants from these regions often resettle on the coast or in the Tirana-Durrës agglomeration. Thus, the depopulation of the North and South by internal and international migration during the 1990s is confirmed in the recent decade.

Unlike in the case of international migration, it is interesting to note that in all prefectures (except Dibër, Kukës and Tirana) internal migration is higher among women than men. This is mainly explained by the higher rates among women in the peak ages of migration. Up to 25% of women aged 15 to 19 in 2006 resided in another prefecture in 2011. Men presented a much flatter age-profile of out-migration, peaking at 5 to 10%. A comparison of interprefectural out-migration rates estimated at the national level for the twelve months preceding the 2001 and 2011 Census[5], respectively, confirms a strongly increasing demographic selection of internal migration – more than that of international emigration (Figure 21).

(5) The former Census does not report internal migration for a five-year period.

Figure 21. Sex and age-specific intra-prefectural out-migration rates (scaled), Albania 2000-01 and 2010-11



Sources: Census 2001, 2011.

Whereas in 2000-01 entire families left their regions of origin (i.e. the age-profile was flat), out-migration mainly concerned adults aged less than 30 and, particularly, women aged 18 to 22 (in 2010-11). Thus, internal migration increasingly occurs during life stages characterized by major transition, such as entering into a job, higher level education or, alternatively, marriage. As with international migration, we can therefore conclude that internal migration transformed from a crisis-driven to an opportunity- or amenity-seeking behaviour. Moreover, the strong demographic selection of mainly female migrants must impact on regional levels of reproduction. Internal return flows are rare.

The geographic concentration of internal in-migration did not change when compared to the 1990s. Its focus on Tirana and Durrës, where more than half and 15% of in-migrants headed respectively during the 2000s, is stronger when compared to the geography of immigration. Thus internal migration remains a predominantly rural-to-urban flow in the 2000s, even if many movers settled in rural areas of the cities' outskirts. Combined with return migration, this led to a fast catch-up of the process of urbanisation: More than 50% of the population resided in official urban areas in 2011, up from 36% in 1989. We can conclude that large scale international and internal migration was not only the major factor of population change in Albania since 1989, but also increased its spatial concentration in more urbanized prefectures. More specifically, the attractiveness of the Tirana-Durrës agglomeration is confirmed: 36% of the national population lived there in 2011 against 27% in 2001 and 22% in 1989.

NATIONAL-LEVEL POPULATION PROJECTIONS

LOW GROWTH SCENARIO

HIGH MORTALITY

LOW FERTILITY

HIGH MIGRATION

National-level population projections results: low growth scenario (high mortality, low fertility and high migration), by single age, Albania 2011-2031

Appendix Table 11. Population projections by age **(both sexes)**, low growth scenario (high mortality, low fertility and high migration), Albania 2011-2031

Age	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021

NATIONAL-LEVEL POPULATION PROJECTIONS

MEDIUM GROWTH SCENARIO

MEDIUM MORTALITY

MEDIUM FERTILITY

MEDIUM MIGRATION

National-level population projections results: medium growth scenario (medium mortality, medium fertility and medium migration), by single age, Albania 2011-2060

Appendix Table 14. Population projections by age **(both sexes)**, medium growth scenario (medium mortality, fertility and migration), Albania 2011-2060

Age	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021

NATIONAL-LEVEL POPULATION PROJECTIONS
HIGH GROWTH SCENARIO

LOW MORTALITY

HIGH FERTILITY

LOW MIGRATION

National-level projections results: high growth scenario (low mortality, high fertility and low migration), by single age, Albania 2011-2031

Appendix Table 17. Population projections by age **(both sexes)**, high growth scenario (low mortality, high fertility and low migration), Albania 2011-2031

Age	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021
0	35,750	34,909	35,443	36,036	36,661	37,293	37,900	38,453	38,934	39,335	39,653
1	34,558	35,058	34,277	34,845	35,471	36,130	36,796	37,439	38,029	38,548	38,988
2	35,390	33,880	34,410	33,695	34,293	34,949	35,639	36,339	37,018	37,647	38,208
