- 16.88 The first method is conceptually preferable and from a practical point of view probably more feasible. However, it should be noted that the residual operating surplus could become negative. Whether this is plausible and realistic or a reflection of the estimation method may require further investigation. For industries such as agriculture, the levels of mixed income may be very volatile, with one year of low, or even negative, levels of mixed income followed by a year with very high levels of mixed income. It seems more reasonable to reflect this volatility in the resulting operating surplus.
- 16.89 Like the persons quadrant, remuneration of employees and (imputed) labour income for self-employed could also be provided by age, sex or gender and educational attainment. Some of these may be derived from surveys and other sources, or they may require some methods of apportionment and disaggregation.
- 16.90 The payments quadrant shows time-series estimates of labour income (per person and per hour); labour costs (per job and per hour); remuneration of employees; other costs less subsidies and other allowances to

employers; and (imputed) labour income of self-employed persons.

## **E. Other enhanced measures of labour inputs**

- 16.91 This section covers some additional labour market measures. These labour input measures can be adjusted to provide various degrees of sophistication and quality, to cover for example, full-time equivalents and quality-adjusted labour inputs for use in productivity measurement and other analyses. More details on the measurement of (labour) productivity can be found in chapter 18.

### **1. Labour input measured on a full-time equivalent basis**

- 16.92 Full-time equivalent labour input is the number of full-time equivalent jobs, defined as total hours actually worked by all employed persons divided by the average number of hours actually worked in full-time jobs.
- 16.93 The definition does not necessarily describe how the concept is estimated. Since the length of a full-time job has changed through time and differs between industries, lower quality crude estimation methods should be avoided and more sophisticated ones are to be preferred, such as one that establishes the average proportion and average working time of less than full week, full-time jobs in each job group separately.
- 16.94 The SNA does not recommend full-time equivalent labour input as the preferred measure of labour inputs but actual hours worked. However, if the data are good enough to permit an estimation of total hours actually worked, full-time equivalent labour input should also be estimated and published. One reason is that this facilitates international comparisons with countries which can only estimate full-time equivalent labour input. Since total hours actually worked is the preferred measure of total labour input, the use of full-time equivalents is likely to be gradually phased out.

### **2. Quality-adjusted labour input**

- 16.95 Using total hours actually worked as the input measure for calculating (labour) productivity changes over time implicitly assumes that each hour worked is of the same quality (that is, there are no differences in the qualifications and skill levels of the labour employed). In other words, each hour worked by a highly skilled person, such as a brain surgeon, is assumed to produce the same quantity and quality of output as each hour worked by an unskilled worker. It is possible to produce a quality-adjusted measure of the labour inputs that takes account of changes in the mix of workers over time by weighting together indicators of quality for different grades of workers. (The term quality-adjusted is used as being parallel to the idea of quality-adjusted price indices but it could also be seen as an adjustment for the change in the composition of the workers involved.)
- 16.96 The quality indicators used can relate to variables such as academic qualifications, trade qualifications, experience (typically based on ~~age of the worker~~<sup>s age</sup>), industry of employment and so on. The various populations are weighted together using average hourly wages for a worker falling into each category. The premise behind this approach is that workers are hired only until their marginal price (that is, their wages, including on-costs) is less than the marginal revenue expected to result from their production. The index formula used can be a fixed-weight (Laspeyres) formula or a more sophisticated formula such as the Tornqvist, which takes account of changing weights by using weights from each of the periods in the analysis.
- 16.97 Calculating a quality-adjusted labour input measure using this approach may seem to be very data intensive but does not require more detailed data than that needed for the labour market tables framework.

### **3. Labour input at constant remuneration**

- 16.98 Total hours actually worked and full-time equivalent labour input are both physical measures of labour input. Output too can usually be measured in physical terms such as tonnes or cubic metres. However, this is not done in the national accounts because the basic value per tonne or cubic metre varies so much between products that these physical measures lack general economic significance. Also, the remuneration per hour

or per full-time year of work varies enormously. Physical measures of labour input are only valid if the mix of different kinds of labour is much the same in the different countries or at the different times examined.

- 16.99 Since output is measured both at current prices and in volume terms using constant prices, it is natural to do the same with labour inputs using constant remuneration, as well as with intermediate inputs using constant prices. If, as recommended for the compilation of labour market tables, data on the (imputed) income for the labour input of self-employed persons are available, compensation for all labour input at constant remuneration could be estimated. If this is not the case, the labour input of employees only can be shown at constant remuneration. Whatever the case, both measures have their relevance for analysis.
- 16.100 The measurement of labour inputs at current prices and in volume terms is symmetrical with the measurement of output and subject to the following caveats:
- a. Market prices and market compensation are assumed to measure the relative economic importance of different goods, services and jobs. The advantages and disadvantages of this assumption are the same for inputs as for outputs.
  - b. Although the volume measure and constant remuneration concepts are defined as revaluations of quantities at base period prices or remuneration levels, they can be estimated in practice as the sum, over all groups, of values at current prices or remuneration levels, each divided by an appropriate wage index.
- These group indices are estimates, calculated for a representative sample of jobs or of goods or services, with weights reflecting the relative importance of each of the sub-groups represented by a selected and specified job, or by a selected and specified good or service. In other words, a remuneration index is constructed like a price index.
- 16.101 While the value of (employee) labour input at constant remuneration can be estimated by deflating current values, as mentioned above, the data may also permit the direct approach of multiplying the current number of jobs in each job group by the base-period average annual remuneration for jobs in that job group.

## **F. Specific issues**

### **1. Links to the Standard Occupational Classification**

- 16.102 The occupation refers to the type of work done in the main job by the person employed irrespective of the industry in which the person's job is classified or the status in employment. Given the diverse nature of work done in the various economic activities, it is also recommended to have breakdowns by occupational group according to the International Standard Classification of Occupations (ISCO) for labour input by industry.
- 16.103 Data by occupation also create the building-blocks necessary to provide information on occupational demands. It also allows to assist areas of the country that have clusters of low-paid skills which, in turn, could help to target policy interventions.
- 16.104 Data on labour input with details on occupations are also important inputs to determining the value of the labour input in estimating the own-account production of various intangible assets such as R&D, computer software and data.

### **2. Paid and unpaid household services, and production for own final use**

- 16.105 In contrast to the SNA production boundary, which is used for the integrated framework of the SNA and calculations of GDP/NDP, the general production boundary also includes own account production of unpaid services for own final use by households ([e.g., childcare, meal preparation, cleaning, etc.](#)). Including them in complementary measures to GDP/NDP and providing the number of hours worked on unpaid household work would complement the standard national accounts' measures with more inclusive measures of economic activity, material well-being and the labour inputs required.

- 16.106 The third-party criterion used when defining the scope of activities to be covered is broadly defined as unpaid work performed within the household sector, which could be contracted out to a market service provider under regular conditions. This corresponds to the concepts of “output for own final use – services” and “households providing (unpaid) services to other households” in the ICLS Resolution; see figure 16.2.
- 16.107 More details on extended accounts on unpaid household service work can be found in chapter 34.

### **3. Education, training and human capital**

- 16.108 From a measurement perspective, well-being encompasses data about several elements, including health, education, income, employment, care, consumption and leisure, that collectively support assessment of the progress of people and communities and the extent to which the needs of current generations are satisfied.
- 16.109 The idea of viewing human knowledge and abilities as an asset – as human capital – and to estimate its value is not new, but has gained prominence in recent years, especially in the context of measuring sustainable development. Policymakers are calling for ways to understand and quantify human capital, in order to better understand what drives economic growth and the functioning of labour markets, to assess the long-term sustainability of a country’s development path, and to measure the output and productivity performance of the education sector. The core connections and dependencies between human capital, education, labour and production are depicted in the figure 34.2.
- 16.110 From an SNA perspective, there has been a long-standing discussion on the potential to capitalise education and training expenditures within the integrated framework of economic accounts and recognise human capital as an economic asset on the balance sheet. Thus, although human capital has not been included in the integrated framework of economic accounts for the reasons mentioned in paragraphs 4.118 – 4.121, the discussion is of high relevance for extending and broadening the integrated framework of economic accounts. This has been done by way of recommending the compilation of extended accounts on human capital, education and training. These extended accounts are further elaborated in chapter 34.
- 16.111 The labour market tables provide important elements for monitoring human capital, education and training. Especially the breakdowns of labour input by educational attainment are relevant in this respect. They do not only show the impact of education and training on the labour market but also account for the developments in the demand for different types of labour. In addition, the data on remuneration of labour input by educational attainment would provide important building blocks for the measurement of human capital using an income-based approach, in which human capital is approximated by the net present value of future benefits from education in the form of remuneration of employees.

## Chapter 17: Capital services (chapter 20 in the 2008 SNA, moved upwards, revised title and revised content)

(OLD Chapter 20: Capital services and the national accounts)

### A. Introduction

- 17.1 This chapter differs in content and style from those describing the accounts of the SNA. Its aim is to show how a link can be made between the value of assets used in production and the gross operating surplus generated. This link has been elaborated over a period of about fifty years in a body of knowledge described as the theory of capital services. [In recent years](#), statistical offices have incorporated the ideas from the theory into the measurement of stocks of those assets used in production. Because there is evidence that this approach leads to improved measures of capital stock, it is [recommended](#) that a table supplementary to the standard accounts [is](#) prepared to display the implicit services provided by non-financial assets. The contribution of labour input to production is recognized in [remuneration](#) of employees. By also associating estimates of capital services with the standard breakdown of value added, the contributions of both labour and capital to production can be portrayed in a form ready for use in the analysis of productivity in a way entirely consistent with the accounts of the SNA. [The methods for measuring the contributions of labour and capital to the analysis of productivity are summarized in section F of chapter 18.](#)
- 17.2 The rest of the introduction gives a very general overview of the ideas involved in linking capital services with national accounts. Section B shows how the measurement of capital stock can be aligned with the notion of the efficiency of an asset as well as its price. This is followed by section C showing how to identify flows of capital services within existing entries in the accounts. Section D shows how consideration of the basic link between asset value and contribution to operating surplus can be exploited to determine the appropriate way to account for costs associated with acquiring and disposing of assets and to place a value on assets where limited market price information is available. Finally, section E [summarizes the fundamental methods of capital measurement and](#) discusses a table [on capital services](#).

### 1. The basic ideas of capital services

- 17.3 Non-financial assets give rise to benefits either from being used in production or simply from being held over a period of time. This chapter concerns those non-financial assets that contribute to production and how this contribution is recorded in the accounts. The assets concerned are [any produced fixed assets \(excluding natural capital\), non-produced fixed assets \(excluding natural capital\), or natural capital assets which are used in an on-going basis on](#) production. Valuables give rise to benefits derived from holding them as stores of value rather than using them and so are not covered by this chapter.
- 17.4 Assets appear on the balance sheet of their economic owner and the changes in value between one balance sheet and the next have to be identified and included in the appropriate account. Changes in the value of assets due to changes in absolute or relative prices appear in the revaluation account. Changes due to unexpected events not reflected in transactions appear in the other changes in the volume of assets [and liabilities](#) account. Every other change in value is treated as a transaction and must be recorded elsewhere in the SNA. If the user of the asset is not the legal owner, two sets of transactions are recorded, those giving rise to payments between the user and the owner and those that show the user receiving the benefits of using the asset. These latter are recorded as internal to the user. If the legal owner of the asset is also the user of the asset, only the internal transactions are recorded.
- 17.5 Assets used in production have to be paid for but the payment is not deducted from the value of production in the period the asset is acquired but is spread over the whole of the period the asset is in use in production. For fixed assets, this gradual payment for an asset is recorded as [depreciation](#), which is the decline in the value of the asset due to its use in production. However, assets are not just a charge on production, they also contribute to the profitability of an enterprise by being the source of operating surplus. It has long been commonplace to recognize that operating surplus is the return to capital used in production. [This chapter](#)

presents an articulation of how this surplus is generated and how it relates to the value of an asset and the way in which this value changes during a period. As noted, this articulation is known as the theory of capital services. This terminology sits a bit uncomfortably with national accountants since the services referred to are not the outputs of production in the way that transportation or education services, for example, are. Nevertheless, the terminology is well established and should not in itself give rise to problems as long as it is remembered that capital services are not produced services. Alternatively, capital services can be thought of as simply the term for the way in which the changes in the value of assets used in production are captured in the production account and the balance sheet.

- 17.6 Much of the impetus for identifying the entries associated with capital services in the national accounts has come from those interested in the analytical uses that can be made of the information, especially for productivity studies. Because much of this work has been undertaken by researchers, it is perhaps inevitable that the rationale and reasoning behind the proposals should have been expressed in a rather academic manner, in particular making extensive use of sometimes rather complex algebra. This chapter takes a different approach. It aims to show that, rather than introducing a new concept into the SNA, capital services can, in theory, be identified within the existing accounts. Further, recognizing this can lead to improvements in the estimates of depreciation, which are currently required in the production accounts, and of the values of capital stock, which are required in the balance sheets. The derivation of information analytically useful for productivity studies can thus be seen as a by-product of improved national accounts compilation practices and not an additional exercise. The explanation is done in terms of highly simplified numerical examples but still aims to demonstrate the connection between the concepts referred to in studies referring to capital services and the national accounts approach to the valuation of capital and the derivation of stock levels.
- 17.7 The explanation given here is to some extent superficial since it is intended to give an overview of the concepts and indicate in general terms why the theory of capital services is relevant to national accountants. For a deeper understanding of the subject, reference should be made to the two OECD manuals on the subject, *Measuring Capital* (2009) and *Measuring Productivity* (2001), and some of the practical and theoretical work referenced in those manuals.

## B. Valuing capital stock

- 17.8 Estimating the value of capital stock is not a straightforward process. Whereas it is possible to measure all new capital formation undertaken in a year directly and simply aggregate it, estimating the total value of a stock of assets, even of the same basic type, but with differing characteristics and of different ages, is not simple. In theory, if there were perfect second-hand markets for assets of every specification, these observed prices could be used to revalue each asset at the prices prevailing in a given year, but in practice, this sort of information is very seldom available. Even if information from a second-hand market is available, there are a number of potential problems with using it to revalue other assets: the market may be extremely thin, so that the assets offered for sale on second-hand markets may be unrepresentative of the assets that are not offered for re-sale; and the prices for second-hand assets may be close to their scrap value, thus not providing a good representation of the capital services that can be derived from them in the remainder of the service life. See the discussion of prices from second-hand markets in paragraphs 4.164 to 4.166 and 4.307. Thus measures of capital stock must be derived indirectly and this is conventionally done by making assumptions about how the price of an asset declines over time and incorporating this in a model based on the perpetual inventory model (PIM). Basically the PIM writes down the value of all assets existing at the beginning of the year in question by the reduction in their value during the year, eliminates those assets that reach the end of their useful lives in the year and adds the written-down value of assets acquired during the year. This routine is so well established that it is possible to overlook the assumptions it rests on but it is an investigation of these assumptions that reveals the dual benefits of deriving capital service values.
- 17.9 In the absence of observable prices, the value of an asset may be determined by the present value of its future earnings. Economic theory states that in a well functioning market (suitably defined) even when prices are observable, this identity will hold also. There are thus two sorts of questions that may be posed about the value of an asset; (i) how much would it fetch if sold, and (ii) how much will it contribute to production over its useful life. The first of these is the traditional question asked by national accountants; the second is basic to studies of productivity. However, these two questions are not independent.

## 1. Knowing the contribution to production

- 17.10 Suppose an asset will add values of 100, 80, 60, 40 and 20 to production over the next five years. For simplicity assume all products have the same prices and there is no inflation. Assume, further, that the real rate of interest is five per cent per annum for all five years.
- 17.11 The value of the asset in all five years can be derived using present value techniques as shown in table 17.1. (For simplicity, in this and all the following examples, the values shown are values at the start of the year so that, when discounting, the factor for the whole year is used. This simplification is made only to facilitate exposition; in practice mid-year figures should be used. It should also be noted that the figures in the tables are rounded and therefore may appear not to add exactly. However, a reader who follows the examples in a spreadsheet will achieve exactly the figures shown.)
- 17.12 The addition to the value of the asset in year 1 from the expected earnings of 80 in year 2 is 76, that is 80 divided by 1.05. (Alternatively, the addition to the value of the asset in year 1 can be viewed as 80 times a discount factor of 0.9524, the reciprocal of 1.05.) The addition to the value of the asset in year 2 from earnings in year 3 is 57 (60 divided by 1.05) and in year 1 is 54 (57 divided by 1.05) and so on. When the value of 100 for the earnings in the first year is added to 76, the value of the second year's earnings in the first year, and to 54, the value of the third year's earnings in the first year and to 35 and 16, representing the value of the earnings in years 4 and 5 in the first year, a value of the asset in year 1 of 282 is derived. When the table is complete, the value of the asset in each of the five years is seen to be 282, 191, 116, 59 and 20.
- 17.13 The decline in value of the asset from year to year can be calculated by deducting each succeeding year's value from the value of the present year. Thus a series of 91, 74, 57, 39 and 20 is derived, a series that sums to 282, the original value of the asset. If the decline in value of the asset (91 in the first year) is deducted from the contribution to production (100 in the first year), the value of income generated in a year results (9 for the first year). To see that this item represents income, consider that the sum of the elements in the first column for years 2 to 5 together (182) represents the value of the same capital stock existing in year 2 but valued in the first year. This value of 182 increases by 9 to 191 between year 1 and year 2. This amount satisfies the criterion for income that it is the amount that the owner of the capital can spend and still be as well off at the end of the period as at the beginning.

**Table 17.1: Example of deriving the value of capital stock from knowledge of its contribution to production**

Discount rate 5%						
	Year 1	Year 2	Year 3	Year 4	Year 5	Sum of 5 years
Contribution to asset value from earnings in :						
Year 1	100					
Year 2	76 ← 80					
Year 3	54 ← 57 ← 60					
Year 4	35 ← 36 ← 38 ← 40					
Year 5	16 ← 17 ← 18 ← 19 ← 20					
Value in year	282 → 191 → 116 → 59 → 20					
Value index (year on year)	1.00	0.68	0.61	0.51	0.34	
Decline in value	91	74	57	39	20	282
Income	9	6	3	1	0	18

- 17.14 Over the five-year period, the value of income is equal to the difference between the sum of the diagonal

elements (300) less the amount of the decline in value (282), or to put it another way, there is an identity between the value of income the asset yields and the discounting inherent in establishing its current value.

## 2. Knowing the value at any time

- 17.15 Now suppose nothing is known about the contribution of the asset to production but the decline in the value of the asset over the five years, due to ageing, is known. If this is postulated in terms of a value index relative to the preceding year's value, and the initial value is known to be 282, then the entries in table 17.2 can be calculated. By design, a value series consistent with the figures in table 17.1 is assumed. Applying the decline in value of 0.68 to the initial value of 282 gives a value of 191 for year 2; applying the value decline of 0.61 to 191 gives 116 for year 3 and so on. (Alternatively a time series of values could be postulated and applied to the initial value.) From this the declines in value of the asset from year to year can be deduced and seen to be identical with those in table 17.1.

Table 17.2: Example of deriving the value of capital stock from knowledge of its decline in price

Discount rate 5%						
	Year 1	Year 2	Year 3	Year 4	Year 5	Sum of 5 years
Contribution to asset value from earnings in :						
Year 1	100					
Year 2	76	80				
Year 3	54	57	60			
Year 4	35	36	38	40		
Year 5	16	17	18	19	20	
Value in year	282	191	116	59	20	
Value index (year on year)	1.00	0.68	0.61	0.51	0.34	
Decline in value	91	74	57	39	20	282
Income	9	6	3	1	0	18

- 17.16 In general this is as far as the PIM goes. Its twofold purpose is to calculate asset values for the balance sheet and the figures for depreciation and these requirements are satisfied at this point. But it is in fact possible to go further. The contribution of the asset to production in the final year (20) is the same as the final year's value. If this is discounted by five per cent, the addition to the value of the asset at the start of year 4 is determined to be 19. Given the value of the asset at the start of year 4 is 59, there must be a figure of 40 contributed to the production in that year. Extending this, for year 3 the value of 116 must consist of 18 representing the contribution to production in year 5 of 20 discounted twice, 38 representing the value contributed to production in year 4 of 40 discounted once and so by residual the value contributed to production in year 3 must be 60. In this way all the top, triangular, part of the table can be completed and the values of the amounts of income in a year be derived just as in table 17.1.

## 3. Age-efficiency and age-price profiles

- 17.17 Although tables 17.1 and 17.2 start from different assumptions, exactly the same complete table results even though they are filled in a different order in the two cases. Table 17.1 starts from assumptions about the declining contribution to production and derives stock values and the decline in value each year. Table 17.2 starts from assumptions about the decline in value of the stock and derives the contribution to production and the decline in value each year. Both techniques give values of stocks to include in the balance sheets and

figures of [depreciation](#). The assumptions made in the two cases must be consistent. In fact it can be shown that every pattern of decline in the contribution of an asset to production (usually called the age-efficiency profile) corresponds to one and only one pattern of decline in prices (usually called the age-price profile).

- 17.18 Given this, it would seem possible to take the information in a set of PIM assumptions and simply derive the contributions to production from these. While it is possible to do this, it is generally held to be preferable to start again by postulating a set of age-efficiency profiles. The reason for this can be illustrated by table [17.3](#).

**Table 17.3: Table 17.2 with a slightly different pattern of price decline**

Discount rate 5%						
	Year 1	Year 2	Year 3	Year 4	Year 5	Sum of 5 years
Contribution to asset value from earnings in :						
Year 1	80					
Year 2	96	101				
Year 3	75	79	83			
Year 4	24	26	27	28		
Year 5	6	6	6	7	7	
<b>Value in year</b>	<b>282</b>	<b>211</b>	<b>116</b>	<b>35</b>	<b>7</b>	
Value index (year on year)	1.00	0.75	0.55	0.30	0.20	
<b>Decline in value</b>	<b>70</b>	<b>95</b>	<b>81</b>	<b>28</b>	<b>7</b>	<b>282</b>
Income	10	6	2	0	0	18

- 17.19 Table [17.3](#) again starts from a series of relative price changes as in table [17.2](#) but these changes are somewhat different. Instead of a series of 1.00, 0.68, 0.61, 0.51 and 0.34, a series of 1.00, 0.75, 0.55, 0.30 and 0.20 is taken. These changes underestimate the rate of decline in value in the second year and assume a faster rate of decline in later years. At first sight they do not seem unreasonable. However, the effect on the contribution to production is considerable and the resulting series of 80, 101, 83, 28 and 7 is quite implausible. What sort of asset would be over twenty per cent more efficient in its second year than in its first and still more efficient in the third year than in the first before declining quickly thereafter? Yet this pattern of flows is still consistent with an initial value of 282, as in table [17.2](#) and with cumulative declines in value adding to this amount over five years.
- 17.20 These are the reasons why it is argued that making assumptions about efficiency decline is likely to lead to superior results for the value of stocks, their decline in value and the income they generate than making assumptions about the rate of price decline. As a further example of why this may also be easier, consider the case of an asset that contributes the same to production, let us say 100, for each of five years and then stops dead, like a light bulb. It is easy to postulate a constant age-efficiency profile but the corresponding age-price profile is much less intuitively obvious and varies according to the discount factor applied.
- 17.21 However, while there are good reasons for using age-efficiency profiles as the starting point, where actual information is available on age-price profiles, even partial information, it should be confirmed that the selected age-efficiency profile is consistent with the observed age-price movements.

#### 4. The special case of geometrically declining profiles

- 17.22 A number of patterns can be postulated for either the age-price or age-efficiency profile. These include straight line depreciation and various non-linear forms discussed in [Measuring Capital](#). One of particular interest is that where the price declines geometrically, that is each year the price (when adjusted for inflation) is a fixed proportion,  $f$ , of the

year before. Because such a series converges to, but never actually reaches, zero, it is difficult to portray it in a table such as those shown above but the interesting characteristic can be derived by means of a little very simple algebra. The SNA recommends that the geometric depreciation method be used as a default option; however, other depreciation profiles may be considered more suitable for certain types of assets (see paragraph 7.280).

Commented [ED1]: GN CM.4

- 17.23 It can be seen from the tables above that the value of an asset at the start of any year,  $V_t$ , is equal to the capital services to be rendered in that year,  $a$ , plus a discount factor,  $d$ , times the value of the asset at the start of the next year,  $V_{t+1}$ . Thus

$$V_t = a + d V_{t+1}.$$

In the case where  $V_{t+1} = f V_t$ ,  $V_t = a/(1-df)$ .

By analogy, if the value of the capital services rendered by the asset in year  $t=1$  is  $b$ ,  $V_{t+1} = b/(1-df)$ . But since  $V_{t+1} = f V_t$ , it follows that  $b$  must be equal to  $af$ . Thus we have the case that the shape of the age-price profile and the shape of the age-efficiency profile are exactly the same.

- 17.24 As noted above, there is one and only one age-price profile corresponding to one age-efficiency profile, so it follows that the geometrically declining profile is the only profile that is the same for both the decline in price and the decline in efficiency. One consequence is that figures for capital stock adjusted for the decline in value are equal to those for capital stock adjusted for the decline in efficiency. This property adds to the reasons that can be advanced for choosing this profile to determine the value of capital stock.

## 5. Practical considerations

- 17.25 As noted at the outset of this section, there are many simplifications built into the examples presented, made in order to facilitate the explanation of the basic theory behind the idea of capital services to those new to the idea. Measuring Capital should be consulted for a more rigorous discussion and for considerations such as the rationale for choosing one age-price (or age-efficiency) profile rather than another, how to estimate life lengths and retirement patterns of assets and the role of expectations in the calculations.
- 17.26 The manual also discusses the fact that the return to capital must be sufficient to cover taxes levied on the asset in question, a point that is ignored here also in the name of simplification.
- 17.27 To be precise, a distinction is made between the interest or discount rate,  $r$ , usually assumed to be five per cent in this chapter, and the discount factor which is the reciprocal of  $(1+r)$ . When  $r$  is 5 percent, the discount factor is 95.24 per cent. When the discount factor is 95.0 per cent, the discount rate is 5.26 per cent.

## C. Interpreting the flows

- 17.28 The tables above generate three time series of particular interest. One is the contribution to production of an asset over time, one is the decline in the value of the asset and one is the income generated by the asset. Obviously the middle term corresponds to depreciation as normally understood in the SNA. The contribution of capital to production is what is called gross operating surplus and so the third time series, income, corresponds fittingly to net operating surplus. However, these flows can be described by alternative names also. The diagonal element of the tables, showing the contribution to production, is also known as the value of capital services. The income element is the return to capital. The rate of return on capital is the ratio of income to the value of capital. For tables 17.1 and 17.2, the income flow as a proportion of the next year's capital stock value (that part not used in the current year) is also five per cent, the same as the discount rate. The alternative terminologies are illustrated in table 17.4.

## 1. Capital services and gross operating surplus

- 17.29 At this point, the national accountant asks how can gross operating surplus be estimated in this way when it is derived as a balancing item in the generation of income account? There are two possible answers to this question. The first answer is that there is not a complete identity with gross operating surplus but the value of capital services is implicitly within it so may be noted as an “of which” item relative to gross operating surplus. Suppose the discount rate chosen is the rate that can be obtained on a bank deposit, say. This determines the amount the user of the asset needs to generate as net operating surplus if the asset is to be cost effective. If the figures for capital services and gross operating surplus are both 100, then the producer has made a reasonable choice of asset; it is earning as much for him as leaving his money in the bank. If he earns a little more than 100, he has done better than leaving the money in the bank. If the national accounts show he has earned 150, say, it may be that the producer has been very lucky indeed, perhaps realizing some monopolistic profits. However, it is also possible that there is some sort of asset he is using that has not been identified in calculating capital services, one possibility being some form of intangible asset. Similarly if the value of gross operating surplus is much lower than the value of capital services estimated, there may be good reason to question the range and valuation of assets assumed to be used in production or the quality of the estimates of gross operating surplus. Thus deriving the value of capital services in this manner is also a valuable tool for checking data quality.
- 17.30 The alternative to treating capital services as an element of gross operating surplus is to equate gross operating surplus with capital services exactly and to do this by determining a rate of return (discount rate) that brings this about. Many traditional analyses of productivity have used this approach and some cross-country comparisons of productivity depend on this assumption. Other studies, used at the industry level, suggest that the variation in apparent rate of return obtained in this way needs to be used, if at all, with very great caution. There is still robust discussion in academic circles about the preferred way of determining the rate of return, exogenously as described in the preceding paragraph or endogenously as described here. One way of interpreting the difference is to say that using an exogenous rate of return simply confronts the cost of capital (capital services) with the benefits (gross operating surplus); the endogenous rate of return gives a single figure to be contrasted with the yardstick of a “normal” rate of return.

Table 17.4: Capital services and SNA terminology

Discount rate 5%						
	Year 1	Year 2	Year 3	Year 4	Year 5	Sum of 5 years
Contribution to asset value from earnings in :	<div>Value of capital services or gross operating surplus</div>					
Year 1						
Year 2						
Year 3						
Year 4						
Year 5						
Value in year	282	191	116	59	20	
Value index (year on year)	1.00	0.68	0.61	0.51	0.34	
Decline in value	91	74	57	39	20	282
	Consumption of fixed capital					
Income	9	6	3	1	0	18
	Return to capital or net operating surplus					

## 2. Prices and volumes

- 17.31 An examination of table 17.1, or indeed any of the others, shows that the value of an asset at a point in time,

such as the start of a year, can be expressed rather neatly as the sum of the capital services rendered in the year plus the discounted value of the asset at the end of the year. This is the starting point of much of the algebraic elaboration of capital services in the literature, but with one important difference. Whereas most national accountants tend to think first in terms of current price aggregates and later (possibly) a breakdown into a volume aggregate plus a corresponding price, most descriptions of capital services run in the other direction. They assume a volume and develop a theory of the corresponding price (the “user cost”). These could be multiplied together to give a current value but much analysis is done using volume or price information.

- 17.32 One reason for working this way is that the assumption underlying table 17.1, that the contributions to production over the life of the asset are known, is not often true in practice. What is known, estimated or simply assumed is an index of how the efficiency changes over time. Equally the value of the asset assumed known in table 17.2 is only known on an asset-by-asset basis when each is new; all other value figures are estimates for reasons explained above. It is possible to use the identity that the start-of-year value of an asset equals capital services rendered in the year plus the discounted end-of-year value, all expressed in index number form and assuming no inflation, into one that expresses the value of the capital services as dependent on the decline in the value of the asset due to ageing (the depreciation element) and the rate of return (the opportunity cost of money). If the impact of general inflation is now taken into account, the price of the capital services (usually called the user cost) can be expressed as depending on the increase in value of a new asset of the same type, the nominal cost of money and the relative year-on-year decline in value of the asset due to ageing.
- 17.33 It is also possible then to have different prices for different sorts of assets and look at differential movements between asset prices and the movements in the general level of inflation. (Table 17.1 was based on the very restrictive assumptions of there being neither absolute nor relative price inflation.)
- 17.34 Another important consideration passed over in the simple numeric tables is the following. For balance sheet data, values at the date the balance sheet is drawn up are needed. For estimates of capital services/gross operating surplus as well as for depreciation and income flows, values at average-year prices are needed. In practice, the mid-year observations are often assumed to be close approximations to the annual averages but this is not always so, especially in times of significant inflation.

## D. Applying the capital service model

- 17.35 Once a theoretical link between the content of gross operating surplus and the capital services embodied in an asset used in production is accepted, there are a number of other beneficial implications for the national accounts. These include the question of the use of land in production, the valuation of non-produced natural resources, the separation of mixed income into the labour and capital components, the measurement of assets with a residual value, the treatment of costs of ownership transfer on acquisition, the treatment of terminal costs, capital maintenance, the valuation of work in progress on long-term projects, an alternative approach to estimating the imputed rentals of owner-occupied dwellings and the separation of the payments under a financial lease into the element to be regarded as the repayment of principle from the element regarded as interest. Each of these will be explained a little further below.
- 17.36 Before discussing land and other non-produced natural resources, it is useful to recall the consequences of an asset being used by a unit not the legal owner of the asset. The important distinction is whether the user does or does not assume the risks associated with its use in production. When the user does not assume the risks, the asset is regarded as being subject to an operational lease. In such a case the payment to use the asset is a rental and forms part of intermediate consumption. The benefits from using the asset in production accrue to the owner in the operating surplus of the production account relating to his leasing activity. (See paragraphs 27.6 to 27.8.)
- 17.37 When the user does assume the risks associated with the use of the asset in production, the benefits from using the asset in production accrue to the user and appear in his operating surplus. This is true of both produced and non-produced assets. The difference between produced and non-produced assets concerns the type of lease existing between the legal owner and the user and the type of property income paid to the legal owner of the asset.

Formatted: Font: 10 pt, Highlight

Formatted: Font: 10 pt, English (United States), Not Expanded by / Condensed by , Highlight

- 17.38 In the case of a produced asset, the user of the asset who assumes all risks associated with the asset becomes the economic owner of the asset. The asset appears on the balance sheet of the economic owner. If the legal owner is different, any payment from the economic owner to the legal owner is recorded as property income payable under a financial lease. (See paragraphs 27.9 to 27.15.)
- 17.39 In the case of a non-produced asset, when the user of the resource and legal owner differ, three different sets of conditions may apply. First, the legal owner may permit the resource to be used to extinction and thus transfers economic ownership of the resource. Second, the legal owner can extend or withhold permission to continued use of the resource from one year to the next and thus retains economic ownership of the resource. In this case the asset remains on the balance sheet of the legal owner but a resource lease between the legal owner and user obliges the latter to pay the former property income in the form of rent. Under the third option the economic ownership of the resource is shared to the extent that both the user and the legal owner are entitled to future economic benefits from the use of the resource. (See paragraphs 27.19 to 27.24.)
- 17.40 For all non-financial assets used in production, the estimation of the value of the capital services associated with the asset allows this to be contrasted with the property income payable for its use to determine whether the use of the asset is cost-effective.

## 1. Land

- 17.41 The first and oldest recognized form of non-produced capital is land. Land is special in that, under good management, the value is assumed to remain constant from year to year except for the effects of inflation in land prices. That is to say, there is no depreciation of land and all the contribution to production can be regarded as income. To show how this can be related to the previous examples, Table 17.5 shows part of a corresponding table for land that contributes 20 to production in perpetuity. A full table would have an infinite number of rows and columns. Here only a few are shown and some very simple algebra (with explanation) is used to explain how the totals are reached.
- 17.42 The value of the first column is the sum of 20, 20 discounted once (the second year's contribution to production discounted once), 20 discounted twice for the third year and so on if not for ever, at least for very many years. With a discount rate of 5 per cent as before, the sum of this column is 420. To see that this is so, consider a simple geometric progression. What is required is the sum of a series that can be written as:

$$S_n = a + ad + ad^2 + ad^3 + ad^4 + ad^5 + \dots + ad^n$$

where  $a$  is the return to the asset in every period and  $d$  is the discount factor. (As noted earlier, for a discount rate of 5 per cent, the discount factor is 95.24 per cent.) If every term in the equation is multiplied by an extra factor  $d$  the result is:

$$dS_n = ad + ad^2 + ad^3 + ad^4 + ad^5 + \dots + ad^{n+1}$$

Subtracting the second expression from the first gives:

$$S_n(1-d) = a(1-d^{n+1})$$

If  $d$  is less than unity (as it will be in a discounting framework) and  $n$  is very large, that last term becomes insignificant and the sum of the series,  $S_n$ , can be determined as  $a/(1-d)$ . In table 17.5,  $a$  is 20 and  $d$  is 0.9524, so the sum of the series is 420.

Table 17.5: The case of land

	Discount rate 5%					
	Year 1	Year 2	Year 3	Year 4	Year 5	... Year 10 ...
Contribution to asset value from earnings in :						
Year 1	20					
Year 2	19	20				
Year 3	18	19	20			
Year 4	17	18	19	20		
Year 10	13	14	14	15	16	... 20 ...
Year 25	6	7	7	8	8	... 10 ...
Year 40	3	3	3	3	4	... 5 ...
Value in year	420	420	420	420	420	420
Value index (year on year)	1.00	1.00	1.00	1.00	1.00	... 1.00 ...
Decline in value	0	0	0	0	0	... 0 ...
Income	20	20	20	20	20	... 20 ...

- 17.43 However, since each of the columns of the table, though one term shorter than the previous one, is also an infinite series beginning in exactly the same way, the sum of each column is also 420. Thus the decline in value of the land from year to year is zero and the whole of the 20 is not just the contribution to production but also income. In national accounts parlance, the gross and net operating surplus are both 20 and there is no depreciation. Equally the value of the capital service and the return to capital are both 20.
- 17.44 As noted above, it may seem slightly odd to think of a non-produced asset contributing a “service” since in national accounts services are always produced. This is simply a reflection of the words chosen by economists to describe the contribution of capital to production without connecting the word “service” to the specific interpretation given to it in the SNA. Similarly one may hear [remuneration](#) of employees described as the cost of labour services.
- 17.45 Another term used for capital services is [resource rent](#) and this initially seems more applicable in the case of land but is also a pitfall. In table 17.5, the [resource rent](#) of land is the extent to which the farmer benefits from using the land for agricultural production (20). This rent accrues whether the farmer is farming his own land or is a tenant farmer. The amount that the tenant farmer is due to pay his landlord is what the national accounts show as rent under property income. In the days when a farmer paid his rent as a share of the crop yield, the link was more obvious. What he retained represented enough to cover his costs and the cost of his own (and any hired) labour. In a monetized economy, the rent payable to the landlord is often agreed a very long time in advance. Comparing the rent earned (as operating surplus) with the rent payable as property income shows whether the agreed rent is “fair” or perhaps excessive relative to the farming income.

## 2. Valuing [non-produced](#) natural resources

- 17.46 There is an increasing interest in placing a capital value on natural resources but, since these assets are seldom sold on the market, there has been doubt about how to do this. Looking at the [resource rent](#) to be earned by a mineral deposit, for example, is one way to solve the problem.
- 17.47 Suppose that a mining company knows the size of the deposit being mined, the average rate of extraction and the costs of extraction of one unit. After allowing for all intermediate costs, labour and the [capital services of all non-](#)

financial assets used in production including any rents paid on the use of non-produced non-financial assets, what is left must represent the resource rent of the natural resource. By applying this to the expected future extractions, a stream of future income can be estimated and from this, using the techniques already described, a figure for the value of the stock of the resource at any point in time.

- 17.48 In fact, the application of the capital service technique goes further than this. In the case of renewable non-produced natural resources such as fish in open waters, if the rate of regrowth is at least equal to the rate of extraction, then the value of the fish does not decline and the rate of extraction is sustainable. However, in the case of a mineral deposit with no natural renewable capability, then it is possible as before to separate the contribution to production into an element showing the depletion (the decline in value of the deposit) and a residual element. Because this residual amount is consistent with the idea of maintaining the level of wealth intact, it can be regarded as income.

Commented [ED3]: WS.6, WS.8, and WS.11 on depletion

### 3. Mixed income

- 17.49 When discussing land, above, it was pointed out that the resource rent of the land was the part that was not otherwise accounted for by intermediate consumption, the cost of hired labour and the capital services rendered by non-financial assets and the labour cost of the farmer. Very often, it is difficult to put a value on the labour of a self-employed person and so this may be merged with the resource rent on land and the capital services rendered by any non-financial assets used and described as mixed income. In principle, though, if a separate estimate of the capital services rendered by fixed assets can be made from information about the services rendered by similar assets in other parts of the economy, then mixed income can be split into its labour and capital components.
- 17.50 In practice this has often proved difficult since the residual amount for self-employed income may turn out to be very small or even negative. Among the possible causes of this are that the value of output may be volatile due to such things as fluctuations in output prices or the impact of weather. The estimates for the capital services may also be high because larger companies are able to make more efficient use of capital, for example using a high value piece of equipment continuously rather than intermittently, or because they actually have other, intangible, assets, which have not been taken into account. This means the capital services for these unmeasured assets are attributed to those that are recognized but this addition is not appropriate for the self-employed worker. Thus the acceptance of the capital services model is unlikely to provide a quick and accurate breakdown of mixed income but it does show the way to probe the data for both large and small enterprises to ensure that capital is being measured comprehensively and consistently.

### 4. Assets with a residual value

- 17.51 Very many assets are used by a single owner until they are worn out and worth nothing. However, this is not the case for all assets. Some are disposed of after a few years, perhaps because the cost of regular maintenance is deemed by the current owner to be too high relative to the value the asset contributes to production. Some airlines, for example, may wish to use the fact that they keep up-to-date fleets of aircraft as part of their advertising appeal. In other cases, for example with construction equipment, the original owner may simply have no further use for the asset.
- 17.52 Table 17.6 shows an example of an asset that is used for only four years and then disposed of for a value of 300. Again for simplicity it is assumed that the disposal value after four years is known when the asset is acquired. For example, the market in used assets may be sufficient to ensure that the value at any point is equal to the remaining services to be delivered by the asset. Inflation is still assumed to be zero.
- 17.53 The top, triangular, part of the table shows the normal calculation of the value of the capital services to be rendered in these four years, a value that at the outset is seen to be 1 107. To this the discounted value of the residual value of 300 must be added. This value is 247, making the total value of the asset 1 354. As in the case where an asset is held to exhaustion, the decline in the value of the asset including the residual value is lower year by year than the decline in the capital services to be rendered in these four years because there is an income element coming from the fact that the remaining value increases as the time for disposal of the asset gets closer. The total of the decline in the value of the asset, to be shown as depreciation, is 1 054. This value, together with the residual value of 300, is equal to the original value of 1 354. The total income (net operating surplus) is 121, the sum of the income arising from the use in production (68) plus the income arising from the unwinding of the discount factor on the terminal value (53).

Table 17.6: An asset with a residual value

Discount rate 5%					
	Year 1	Year 2	Year 3	Year 4	Residual value
Contribution to asset value from earnings in :					
Year 1	400				
Year 2	286	300			
Year 3	227	238	250		
Year 4	194	204	214	225	
<b>Value in year</b>	<b>1 107</b>	<b>742</b>	<b>464</b>	<b>225</b>	<b>0</b>
<b>Decline in value</b>	<b>365</b>	<b>278</b>	<b>239</b>	<b>225</b>	
Income	35	22	11	0	
<b>Residual value</b>	<b>247</b>	<b>259</b>	<b>272</b>	<b>286</b>	<b>300</b>
Income	12	13	14	14	
<b>Joint value</b>	<b>1 354</b>	<b>1 001</b>	<b>736</b>	<b>511</b>	<b>300</b>
<b>Decline in value</b>	<b>352</b>	<b>265</b>	<b>226</b>	<b>211</b>	
Income	48	35	24	14	

- 17.54 Table 17.6 illustrates that the cumulative value of the [depreciation](#) calculated in respect of an asset should be equal to the initial value of the asset, treated as fixed capital formation, less the value to the owner on disposal of the asset. This holds whether the asset passes into use as a fixed asset by another user, is used for another purpose in the same economy or is exported.

## 5. Costs of ownership transfer on acquisition

- 17.55 The costs of ownership transfer incurred on acquisition of an asset are treated as fixed capital formation. This assertion is equivalent to assuming that the services rendered by the asset must be sufficient to cover both the costs of the asset and the costs of ownership transfer. Table 17.7 shows an example where costs of 30 are incurred on the acquisition of the asset in table 17.6. In order for the asset to have exactly the same value as before on disposal, 300, the costs of ownership transfer have to be accounted for during the period in which the owner who incurred the costs uses the asset in production. The figures in the triangular part of table 17.7 are added to those in the corresponding part of table 17.6 giving increased value to the asset in each year until the end of year 4, increased [depreciation](#) and slightly increased income, because the costs of ownership transfer are also viewed as the present value of the extra services required to meet the costs.
- 17.56 If the costs of ownership transfer were to be attributed to the whole life of the asset and not just that part for which the unit that paid the costs owns the asset, there is a mismatch between the calculated value of the asset and the market value demonstrated in the sale at a value of 300. In such a case, the data have to be brought back into reconciliation by means of an entry in the other changes in the volume of assets [and liabilities](#) account but this means that not all of the costs incurred by the initial owner are shown as a charge against gross value added and so income is over-stated. This may be inevitable when assets are sold unexpectedly but in the case of many vehicles and large mobile construction equipment, the purchaser may well take account of the value to be realized on sale after a given period. When this is so, every effort should be made to take account not only of the residual value but also factor the expected life length into the calculations of the amount of [depreciation](#) to be attributed to the costs of ownership transfer so there is no residual value of these costs left on disposal.

Table 17.7: Example of costs of ownership transfer on the acquisition of the asset in table 17.6

## 6. Terminal costs

17.57 Table 17.6 considered the case where an asset had a residual value at the time the current owner disposed of it. It is also possible to have assets that have significantly large costs associated with disposal that the owner is obligated to incur. Examples include the decommissioning costs of nuclear power stations or oil rigs or the clean-up costs of landfill sites. The following discussion is not meant to downplay the practical difficulty of estimating terminal costs, simply to demonstrate why in principle the existence of terminal costs should reduce the value of the asset throughout its life.

17.58 Terminal costs are similar to capital formation in that they should be covered by income generated during the time the asset is used in production. To avoid a negative value of the asset at the end of its life, the expected terminal costs are added to the value of the asset at the time the asset enters the balance sheet, with a counterparty entry of provisions at the liability side, both to be recorded in the other changes in the volume of assets and liabilities account. At the end of the life of the asset, the actual investment expenditures on terminal costs, which lead to a positive change in the value of the asset, are counterbalanced with a reversal of the flows in the beginning of the period, i.e., a decline in the value of assets with a concomitant decline of the related provisions, again recorded as other changes in the volume of assets and liabilities.

Commented [ED4]: WS.9

17.59 Table 17.8 shows an example of how terminal costs should be recorded. The analysis of the data is similar to that for table 17.6 but also includes the recording of provision charges for the terminal cost (see paragraphs 11.223 to 11.225). The value of the capital services to be provided by the asset in use is still 1 107. The value of the asset must also account for the terminal cost of -300 which will be incurred when the asset is disposed of. Subtracting the present value of the anticipated terminal cost of -247 from the present value of the capital services implies that the initial value of the asset of 860 is lower than without the presence of terminal costs. The initial value of 860 is recorded as capital formation in year 1. The terminal cost will be recorded as capital formation at the time of disposal, but it is important that the depreciation associated with the terminal cost be charged against the income earned during the time that the asset is in service. Hence, two entries for provisions are made in the other changes of assets and liabilities account. The present value of the terminal cost (with a positive sign) is added to the value of the asset, allowing the terminal investment to be written off. To maintain the correct contribution of the asset to net worth, a contingent liability (a provision) of the same amount is also entered. The value of the asset shown on the balance sheet, 1 107 in year 1, is equal to the capital formation for the initial acquisition of the asset plus the discounted value of the capital formation associated with the terminal costs. When discounting is used, the carrying amount of a provision increases in each period to reflect the passage of time. These amounts (shown in the row "unwinding of the discount") also need to be recorded as positive and negative entries in the other changes in volume of assets and liability

account each year. The depreciation recorded should equal the change in the value of the asset plus the unwinding of the discount to ensure that the total value of the terminal costs are fully depreciated. If this combined amount is recorded as depreciation, then the cumulated value of depreciation, 1 160, is equal to the capital formation associated with the acquisition of the asset plus the capital formation associated with its disposal of the asset. At the time that the asset is decommissioned and the terminal costs are incurred, gross capital formation of 300 is recorded. In addition, the provisions are reversed, showing an entry -300 in other changes in volume of assets and 300 in other changes in volume of liabilities, bringing the cumulative value of the provision charges to zero.

~~17.59~~17.60 Anticipated costs on ownership transfer on disposal of an asset, including legal fees, commission, transport and disassembly, etc., should in principle be treated in the same way as terminal costs.

Table 17.8: An asset with a terminal cost

	Discount rate 5%					Sum of 4 years

## 7. Major repairs and renovations

~~17.60~~17.61 Major repairs and renovations that extend the life of an asset are treated as capital formation and the value of the repairs and renovations is added to the value of the asset before the work was undertaken. The example of costs of ownership transfer on acquisition of an asset can be applied directly in this case, excepting only that the costs are incurred in a year other than the year of acquisition. The value of the capital repairs is supposed to be equal to the discounted value of the increased services that the asset will yield, either by increasing the services in each of the remaining years of the initial life length, or extending the life length, or both.

~~17.61~~17.62 The value of the capital repairs can be analysed by merging the value with that of the asset in question and reworking all the calculations of the services to be rendered, the income generated and the

depreciation for the asset and the maintenance taken together. However, as table 17.7 shows, it is also possible to leave the calculations for the asset as they were and simply aggregate them with a separate analysis of the maintenance undertaken as if it related to a wholly new asset.

## 8. Work-in-progress for long term projects

17.6217.63 Table 17.9 relates to an asset with a final value of 200 that is to be constructed over a period of four years. One possibility is that, assuming no inflation, work in progress of 50 should be recorded in each of the four years. However, consistent with the notion of discounting future income, an alternative view is preferable. Suppose still that there is a discount rate of five per cent. In each year, the value of the completed asset in each of years 1 to 3 will be 172.8, 181.4 and 190.5, each of which will cumulate to a value of 200 after, respectively, three, two or one years accumulation in value of 5 per cent. Dividing each of these by four implies that even if equal amounts of work are put in place in each year, the values to be recorded should be 43.2, 45.4, 47.6 and 50.0. In addition, though, there will be income arising from a return to the work already put in place. This would give a time series for the work put in place and other income of 2.2, 4.5 and 7.1 in each of years two to four giving the value of the partially complete structure as 43.2, 90.7, 142.9 and 200.0. These are the values that a purchaser of the partially completed structure would be willing to pay, given that he would forgo the income from the finished structure for up to three years.

Table 17.9: Valuing work-in-progress spanning several years

	Discount rate 5%			
	Year 1	Year 2	Year 3	Year 4
Value of final product in each year	172.8	181.4	190.5	200.0
Value of construction activity (one quarter of final value)	43.2	45.4	47.6	50.0
Income accruing on work put in place				
In year 1		2.2	2.3	2.4
In year 2			2.3	2.4
In year 3				2.4
End year value	43.2	90.7	142.9	200.0

## 9. Owner-occupied dwellings

17.6317.64 The SNA specifies that an imputed rental on owner-occupied housing should be included in the production boundary and form part of household consumption. In a situation where there is either no rental market in such properties or only a very limited one, this is difficult to implement. Cross-country comparisons of the results (as in the International Comparison Program) show that the different techniques used produce highly variable results. Here too, the use of the techniques described in this chapter may be helpful.

17.6417.65 In the example for land, it is possible to deduce a value of 420 for the land that yielded resource rent of 20 every year in perpetuity. While modern houses do not last forever, if they are assumed to last for, say, fifty years the discount factor applied over this period gives contributions to the value of the asset that are negligible at the end and again it may be supposed that, if the value of the house is 420, then the imputed rental is 20. Given that the market for houses is much better established than for rented housing, this may also provide a source of useful and comparable data for a troublesome area of national accounts. However, this method should be used with caution since houses are often bought in the expectation of making significant real holding gains. It should also be recognized that the rental for a house usually includes land rent.

## 10. A financial lease

<sup>17.65</sup><sup>17.66</sup> The process of discounting future income streams to determine present value applies to financial assets as well as to non-financial assets. Consider an agreement with a bank to borrow 1 000 over a period of five years at five per cent interest. The total amount to be paid to the bank will be 1 100 at a rate of 220 per year. But, as table 17.10 shows, each year's payment does not consist of repayment of principal of 200 and interest of 20. Interest is payable on the remaining balance, so is highest in the first year and is zero in the last year. (This is a result of the simplifications used in the chapter. In practice, interest would be charged daily and so even in the last year some interest would be payable. However, the way in which the balance between interest and repayment of principal changes over time as the loan is repaid holds.)

<sup>17.66</sup><sup>17.67</sup> The arithmetic behind table 17.10 is indistinguishable from any of the other tables in this chapter demonstrating that the same principles hold for valuing financial assets as for non-financial assets. The same methodology that can be used to show how much of the contribution to production is [depreciation](#) and how much contributes to net operating surplus can also be used to show how much of the payment to the bank is a repayment of capital and how much is interest. Both [depreciation](#) and a repayment of capital feature in the accumulation accounts as changing the value of the stock of assets. The contributions to net operating surplus and interest are both income flows and are shown in the current accounts.

<sup>17.67</sup><sup>17.68</sup> This duality is especially important when an asset is acquired under a financial lease. In this case, table 17.10 can be used to show both the change in value of the asset and the change in the loan taken out to pay for it. Cost benefit analyses of the merits of borrowing to acquire assets also depend on this sort of calculation. Unless the asset can contribute at least as much to production as the interest due to the lender, it is not a good investment. Even if a producer has sufficient funds available to purchase an asset without borrowing, it makes sense to undertake such an analysis since the alternative to acquiring the asset is to convert the funds to an asset that will either earn income or appreciate and yield holding gains.

Table 17.10: The case of a financial [lease](#)

	Interest rate 5%					Sum of 5 years
	Year 1	Year 2	Year 3	Year 4	Year 5	
Contribution to loan value from payments due in :						
Year 1	220					
Year 2	210	220				
Year 3	200	210	220			
Year 4	190	200	210	220		
Year 5	181	190	200	210	220	
Loan value in year	1000	819	629	430	220	
Repayment of principal	181	190	200	210	220	1000
Interest	39	30	20	10	0	100

## E. Capital measurement

<sup>17.69</sup> Capital services is just one part of capital measurement in the SNA. This section provides an overview of a set of accounts that encompass all aspects of capital measurement, including wealth stocks, productive stocks, depreciation, revaluation, other changes in volume of assets and liabilities, and capital services. These measures are all closely associated with the PIM, and if they are compiled in an integrated manner, the quality of key measures such as net domestic product, net worth and productivity will be enhanced. These measures encompass at least fixed assets and natural resources, but more broadly could encompass other non-financial assets that might be compiled using the PIM including inventories, valuables and consumer durables (which are allowed as a supplementary item on the balance sheet).

**Commented [ED5]:** New section based on recommendation from GN CM.4 that chapter 17 "should provide an all-inclusive coverage of measuring capital: all stocks and flows of fixed assets, natural resources and land. The new chapter should cover and explain the differences between both wealth and productive capital stocks." The section also includes the content of the 2008 SNA section E, "A supplementary table on capital services", as its final subsection.

## 1. Basics of capital measurement

17.70 Because capital plays two basic roles in the SNA, as a contributor to wealth and income and as a contributor to the production process, the capital measures in the SNA fit in two broad categories. Wealth stocks represent the value of the capital stock and show how these add to the net worth of institutional sectors and the total economy. Associated with wealth stocks are flows such as capital formation, depreciation, and other changes in assets and liabilities that are related to the measurement of net value added from production, net income and the acquisition of wealth. These measures are associated with changes from period to period in the value of the wealth stock and contribute to the important net measures that appear in the national accounts, institutional sector accounts and balance sheets. The second category of measures is associated with the efficiency of the stock of assets in providing capital services. A measure of stock that is adjusted for current and past declines in efficiency is called the productive stock, and it is used in preparing aggregate measures of capital services. The set of measures that focus on capital services are used especially for estimating productivity and the contribution of the capital stock to economic growth. While both sets of measures are constructed from the same capital flows, it is important that compilers and users of the data should clearly distinguish between the two.

17.71 Before getting into the details of measurement, it is appropriate to recall briefly the various simplifying assumptions that underlie the numeric examples in the chapter, assumptions that would be totally inappropriate in serious estimation of capital service flows. The most important are:

- a. Somewhat different figures would emerge if any of the tables were to be calculated for the start of year, end of year or mid-year. Mid-year flows need to be discounted by half the annual discount rate to give start of year figures, for example.
- b. The assumption that there is no price inflation, either overall or between different assets, is clearly unrealistic. Changes due to price movements need to be separately identified and included in the revaluation account.
- c. The general preference for an age-efficiency approach to determine the value of capital stock should not be taken to mean that information on age-price decline, when such exists, is to be ignored. The solution is to find an age-efficiency pattern that matches the observed decline in prices. Where such a match can be made, this may inform the choice of age-efficiency declines where no matching price information is available. Use of geometric depreciation simplifies this choice by using a single depreciation rate to describe both the age-efficiency and age-price patterns.

17.72 There is a question about the appropriate level of detail to be used for assets. They are very diverse and even products that appear superficially similar, such as aircraft, may have quite different specifications. This is a problem that must be resolved whatever means of determining a stock figure for assets is used. The final choice may be a source of inaccuracies, or conversely, may lead to extra resource cost for little improvement in the results.

17.73 So far, this chapter has mostly focused on a single asset, for which it is assumed that the owner of the asset is able to calculate, at least approximately, its capital service—the contribution of the asset in the production process—over the anticipated life of the asset. Using this information, it is possible to derive the basic stocks and flows associated with the asset.

17.74 For national accounts compilers, the situation is different. There is a vast variety of assets, including non-produced natural resources and fixed assets of different ages. Information on capital services is not readily available and must be inferred from other information. Prices of fixed assets may only be observed when the asset is initially acquired. The assets can be organized by classifications, such as the SNA's classifications of fixed assets and of natural resources, and possibly by more detailed classifications such as the Central Product Classification, Version 2.1. The data on fixed assets recorded in company accounts may be of limited usefulness to compilers because it is recorded at historical cost.

17.75 In practice, the measurement of capital is usually based in part on estimates that may have been prepared as part of the compilation of GDP. These estimates need to be organized in time series to support a PIM. For fixed assets, including cultivated biological resources yielding repeat products, the basic information required for the PIM is:

- a. Time series of estimates of gross fixed capital formation (GFCF) by type of asset (according to the

**Commented [ED6]:** This paragraph and the next one are from 2008 SNA 20.69 to 20.70 with some editing.

SNA's classification of fixed assets) at current prices and in volume terms;

- b. Time series of price indices that can be used as deflators for each type of asset;
- c. An age-price profile (or an associated age-efficiency profile) for each type of asset. If geometric depreciation is used (as the SNA recommends as a default option—see paragraph 7.280), then the only information needed is a depreciation rate for each type of asset. In paragraphs 17.22 to 17.24, one can see that in the case of geometric depreciation, the age-price profile and the age-efficiency profile are the same. If geometric depreciation is not used, the age-price profile must be derived from the age-efficiency profile (or vice versa) to ensure that the two profiles are consistent (see Annex D of *Measuring Capital*).
- d. If other changes in the volume of assets are relevant for a type of asset, those other changes in volume should be added to the value of the assets.
- e. To support the calculation of net value added and net operating surplus by industry, as well as multifactor productivity estimates by industry, the PIM will need to be calculated by industry as well as by type of asset. Therefore, time series of fixed capital formation and other changes in volume of assets by type of asset need to be prepared for each industry.
- f. To support wealth and depreciation estimates for institutional sector accounts, the PIM will need to be calculated by institutional sector as well as by type of asset. Therefore, time series of fixed capital formation and other changes in volume of assets by type of asset need to be prepared for each institutional sector. Typically, price indices and depreciation rates differ across types of assets but are assumed not to differ between institutional sectors for each type of asset.

## 2. Calculating depreciation

- 17.76 Depreciation is defined as “the decline, during the course of the accounting period, in the current value of the stock of fixed assets owned and used by a producer as a result of physical deterioration, normal obsolescence or normal accidental damage” (see paragraph 7.264). A decline in value during the accounting period can be understood as the sum of two components. One component is the price change that reflects the price movement of the asset class under consideration, *given a particular age* (and measured, for example, by comparing the price of a new asset at the beginning of the period with the price of a new asset at the end of the period). Another component is the price change that reflects the ageing of the asset *given a particular price level for the asset class* (and measured, for example, by comparing the price of a new asset with the price of a one-year-old asset). Depreciation is measured as the price change due to ageing, thereby controlling for the overall movements in asset prices. This fits with the idea that “depreciation must be measured with reference to a given set of prices, i.e. the average prices of the period” (see paragraph 11.218).
- 17.77 The measurement of depreciation is directly associated with the age-price profile of an asset or of a cohort of assets. The rate of depreciation of a t-year-old asset is the difference in the price of a t-year-old asset and a t+1-year-old asset, expressed as a proportion of the t-year old asset. For geometric depreciation, this proportion is constant for all years t.
- 17.78 Careful consideration should be given to selecting the depreciation rates, or more generally, the age-price profiles. Some fixed assets (such as motor vehicles) have prices from sales of used, or second-hand assets that can be used to directly estimate the depreciation rate. In other cases, information on the typical service lives of the asset can be used. The selection of depreciation rates is discussed in more detail in *Measuring Capital*.

## 3. Calculating the net (“wealth”) stock

- 17.79 The stock of assets surviving from past periods and corrected for depreciation is the “net” or “wealth” capital stock. The net stock is valued as if the capital good (used or new) were acquired on the date to which a balance sheet relates. The net stock is designed to reflect the wealth of the owner of the asset at a particular point in time. Hence, the notion of “wealth” stock seems more descriptive than “net” stock because there are other types of “net” capital measures. The *wealth* stock is the measure that enters balance sheets of the

[national and of institutional sectors.](#)

#### **4. Calculating productive stock**

17.80 The stock of a particular type of asset surviving from past periods and corrected for its loss in productive efficiency is the productive capital stock. Productive stocks constitute an intermediate step towards the measurement of capital services. The flow of capital services is assumed to be proportional to the productive stock of an asset class. If the factor of proportionality is constant, the rate of change of capital services will equal the rate of change of the productive stock. The rate of change of the productive stock is assumed to be the volume component when it comes to splitting the change in the total value of capital services at current prices into a price and a volume component. The concept of a productive stock is only meaningful at the disaggregated level of a particular type of asset. Once each asset's productive stock is combined with the corresponding capital service price, the resulting value represents the flow of capital services, which is the relevant variable for aggregation across different types of assets.

#### **5. Perpetual inventory model for non-renewable mineral and energy resources**

17.81 For non-renewable mineral and energy resources, the PIM should be applied for each type of asset, with the resulting estimates then summed across asset types for wealth stocks or aggregated using chain indices for volume estimates. Data may be available on stocks and extraction in physical volume terms. The valuation of stocks is explained in paragraphs [14.56](#) to [14.57](#) and the measurement of depletion is explained in [11.232](#) to [11.234](#). A PIM for each type of asset can be calculated in physical terms or in constant prices. Compared with fixed assets, the PIM for a mineral resource is simpler in that depreciation does not need to be calculated. The opening stock for each year is carried forward from the closing stock of the previous year. There is no gross capital formation, so additions to the stock consist solely of other changes in the volume of assets (if any), which might include new discoveries, for example. Extraction of the resource is recorded as depletion and is subtracted in the calculation of the closing stock. The closing stock at the end of the year is equal to the opening stock plus other changes in the volume of assets less depletion.

#### **6. User costs**

17.82 Capital services are considered the appropriate measure of capital input in the production process, but to make them useful [one](#) needs to develop measures of value, price and volume of capital services. Depreciation does not represent the full cost of using a fixed asset, as [one](#) can see by imagining a case where the fixed asset is leased by its owner to another unit that uses it in production. The owner will charge a rental price that includes not only depreciation but also a net return on capital that reflects the financing costs of capital.

17.83 If there are rental markets, observed rentals could provide a first approximation to the user cost of capital for owner-users of the same assets. While rental markets may be common for some types of assets, such as dwellings, for most asset types rental prices are not available. Thus, various components of cost must be added up to approximate the cost of capital services. In the simplest case, three main cost elements are considered: (i) the cost of financing or the opportunity cost of the financial capital tied up through the purchase of the asset (which is used for calculating the return on non-financial assets used in producing non-market output) (ii) depreciation, i.e. the value loss due to ageing; (iii) revaluation, i.e. the expected price change of the class of assets under consideration. National accounts data on depreciation and prices can be used for estimating components (ii) and (iii), while component (i) might be based on gross operating surplus (along with a portion of gross mixed income) as part of the calculation of the net return to capital. Implementing the user cost methodology requires various assumptions that are discussed in [Measuring Capital](#).

#### **7. Aggregation**

17.84 The final step in the compilation of capital stock and capital service statistics is to aggregate across asset

types to calculate aggregate stocks for institutional sectors, industries or the total economy. In current prices, aggregation is taken as the simple summation of stocks or capital services across asset types. Balance sheets are generally compiled in the current prices of the beginning/end of the period.

17.85 For aggregation in volume terms, the calculations described in chapter 18 are typically applied. Because the wealth stock is presented in current prices in the balance sheet, it may not be necessary to calculate it in volume terms. But if desired, the volume measure of the wealth stock can be calculated.

## 8. A table on capital services

17.6817.86 This section describes a table that can be compiled to compare data coming from the standard national accounts tables for the elements of gross value added with those derived from applying the theory of capital services to the national accounts data on capital stock. The table can be prepared in current prices and in volume terms, with the capital service values in volume terms used for analysis of capital and multifactor productivity as described in section F of chapter 18.

17.6917.87 The first level of detail that might be examined is given in table 17.11. This assumes that information on value added by institutional sector is available. The figures for operating surplus for non-financial and financial corporations may be compared with capital services from fixed assets used by these sectors adjusted as necessary for non-produced natural resources, other non-produced non-financial assets and inventories. The figures for operating surplus of general government and NPISHs and those for capital services of those sectors must be equal except for possible adjustments for inventories and depletion. This is because by convention the net return to capital on assets used in non-market production is derived from an opportunity cost perspective when output is estimated as the sum of costs (see paragraphs 4.295 and 4.296). The capital services for household dwellings should match operating surplus for households and the figure for capital services for other household unincorporated enterprises is to be compared with the national accounts figure for mixed income (which should include a labour remuneration element also).

Commented [ED7]: Issue X.55

Table 17.11: The outline of a table on capital services

National accounts data	Total/Gross	<u>Depreciation</u>	<u>Depletion</u>	Net
Gross value added				
<u>Remuneration</u> of employees				
Mixed income				
Operating surplus				
Non-financial corporations				
Financial corporations				
General government				
NPISHs				
Households				
Taxes less subsidies on production				
<b>Capital services</b>		Capital services	Decline in value	Return to capital
<u>Total economy</u>				
Fixed assets				
Market producers (excluding households)				
Non-financial corporations				
Financial corporations				
Non-market producers				
General government				
NPISHs				
Households				
Dwellings				
Other unincorporated enterprises				
Natural resources				
Inventories				

**Commented [ED8]:** The line for the total was omitted from the 2008 SNA version of the table. If multifactor productivity is calculated for the total economy, the total (in volume terms) is needed.

## Chapter 18: Measuring prices, volumes and productivity

(revised title and revised content)  
(OLD Chapter 15: Price and volume measures)

### A. Introduction

- 18.1 Chapter 14-15 describes how the goods and services account may be compiled and elaborated within a supply and use table. The changes in the values of flows of goods and services can be directly factored into two components, one reflecting changes in the prices of the goods and services concerned and the other the changes in their volumes. One major advantage of compiling price and volume measures within an accounting framework, such as that provided by the supply and use tables, is that a check is provided on the numerical consistency and reliability of the set of measures as a whole. This is particularly important when every flow of goods and services in the economy has to be covered, including non-market goods and services whose valuation is even more difficult in volume terms than at current prices.
- 18.2 Another advantage of compiling price and volume measures within an accounting framework is that implicit price or volume measures can be derived for certain important balancing items. In particular, gross value added can be measured in real terms by subtracting intermediate consumption in volume terms from output in volume terms, the so-called “double deflation” method. Double deflation may be used at the level of an individual enterprise, industry or sector. However, the primary objective of the SNA is not simply to provide guidelines on measures of changes in prices and volumes for the main aggregates of the SNA but to assemble a set of interdependent measures that make it possible to carry out systematic and detailed analyses of inflation and economic growth.

### 1. Index number theory

- 18.3 Section B gives an overview of the theory of index numbers as applied in the SNA. [New manuals](#) have been published on the theory and practice of consumer price indices (CPIs) and on producer price indices (PPIs). These are *Consumer Price Index Manual: Theory and Practice* (Concepts and Methods), (International Monetary Fund, International Labour Organization, International Monetary Fund, Statistical Office of the European Union (Eurostat), United Nations Economic Commission for Europe, Organisation for Economic Co-operation and Development, Eurostat, United Nations Economic Commission for Europe and the World Bank (2004/2020)) and *Producer Price Index Manual: Theory and Practice*, (International Labour Organization, International Monetary Fund, Organisation for Economic Co-operation and Development, United Nations, Economic Commission for Europe and the World Bank (2004).) A further manual on export and import price indices (XMPIs), *Export and Import Price Index Manual: Theory and Practice* (International Labour Organization, International Monetary Fund, Organisation for Economic Co-operation and Development, United Nations Economic Commission for Europe and World Bank (2009)). In particular chapter 2 of the CPI manual, chapter 14 of the CPI and PPI manuals and chapter 15 of the XMPI manual outline how such indices fit into the framework of the SNA.
- 18.4 The first topic in section B concerns the choice of an appropriate methodology for compiling inter-temporal price and volume measures for flows of goods and services in a national accounting context. Section B also deals with the consequences of price variation due to price discrimination; that is, how to treat goods or services that are sold to different purchasers on the same market in the same period at different prices. Such differences need to be clearly distinguished from price differences attributable to differences in qualities. This section also discusses the treatment of changes in quality over time, including the appearance of new products and the disappearance of old products.

### 2. Inter-temporal price and volume series

- 18.5 Section C shows how the considerations in section B can be applied to the SNA and time series of volumes and prices

**Commented [ED1]:** References to several manuals or handbooks have been updated to reflect new editions published since 2008.

be derived. It discusses not only the elements of the goods and services account but also how stocks of non-financial assets can be decomposed into price and volume elements. Further, the section addresses the question of expressing key aggregates of the SNA that do not themselves have price and volume components in real terms, allowing an analysis of the impact of terms of trade on national income, for instance.

- 18.6 Like section B, section C does not aim to be exhaustive in its coverage but draws on, and refers to, other manuals, specifically the *Handbook on Prices and Volume Measures in National Accounts* (Eurostat, 20042016) and chapter IX of *Quarterly National Accounts Manual* (International Monetary Fund (IMF), 2017).

### **3. Real income**

- 18.7 Section D addresses the question of expressing key aggregates of the SNA that do not themselves have price and volume components in real terms, allowing an analysis of the impact of terms of trade on national income, for instance.

### **4. Volume measures for particular products**

- 18.8 The methods discussed in Section C of this chapter can be used to appropriately derive volume and price measures for most products. For a few products that have unusual characteristics, this general guidance may not be sufficient, and Section E provides more specific guidance for those cases. The specific guidance in this section draws from handbooks such as Eurostat, *Handbook on Prices and Volume Measures in National Accounts*, 2016 edition and other handbooks that are cited in the section.

### **5. Productivity**

- 18.9 Section F describes measures of productivity, which measure changes in the volume of output relative to changes in the volume of inputs. These measures are ratios in which the numerator is a volume measure of output or value added and the denominator is a volume measure of one or more inputs, especially of labour, capital or the combined contributions of labour and capital. This section draws on the handbooks, *Measuring Capital* (Organisation for Economic Co-operation and Development (OECD), 2009) and *Measuring Productivity* (OECD, 2001).

### **3.6. International price comparisons**

- 18.718.10 Although most price and volume index numbers were developed to measure changes in prices and volumes over time, they can also be adapted to compare levels of prices and volumes between different regions or countries in the same period of time. Such comparisons are needed in order to be able to compare standards of living, levels of economic development or levels of productivity in different countries.

- 18.818.11 These topics are addressed in section DG, first in theoretical terms and then in terms of the implications for national accountants. *Measuring the Real Size of the World Economy: The Framework, Methodology, and Results of the International Comparison Program—ICP* (World Bank, 2013) describes the methodology underlying the International Comparison Program (ICP).

### **4.7. Further information**

- 18.918.12 This chapter aims to do no more than introduce the most important concepts and considerations of the application of index number theory to the derivations of volume series within the SNA. Further information should be sought from the other manuals cited.

## **B. An overview of index number theory**

### **1. Quantities, prices and values**

~~18.10~~18.13 For each individual type of good or service it is necessary to specify an appropriate quantity unit in which that good or service can be measured. Goods or services may be supplied in units that are either discrete or continuously variable. Automobiles, aircraft, microcomputers, haircuts and appendectomies are examples of goods or services provided in discrete or integral units. The quantities of such goods and services are obtained simply by counting the number of units. Oil, electricity, sugar and transportation are examples of goods or services provided in units that vary continuously in respect of characteristics such as weight, volume, power, duration and distance. The choice of physical unit, and its price in relation to the unit selected, is therefore a matter of convenience. For example, the price quoted per tonne is one thousand times greater than one quoted per kilo. As long as the price is expressed in a manner consistent with the unit of volume, the value ( $v$ ) at the level of a single, homogeneous good or service is equal to the price per unit of quantity ( $p$ ) multiplied by the number of quantity units ( $q$ ), that is:  $v = p \times q$ .

### Additivity of quantities, prices and values

~~18.11~~18.14 Certain important properties in relation to the additivity of quantities, prices and values may be briefly noted:

- a. Quantities are additive only for a single homogeneous product. For example, it is not economically meaningful to add 10 tonnes of coal to 20 tonnes of sugar. Less obviously, the addition of 10 automobiles of one type to 20 automobiles of another type would not be economically meaningful either if they differ in quality.
- b. **The price of a good or service is defined as the value of one unit of that good or service.** It varies directly with the size of the unit of quantity selected and in many cases can be made to vary arbitrarily by changing the unit of quantity, for example, by choosing to measure in tonnes instead of in kilograms. Prices, like quantities, are not additive across different goods or services. An average of the prices of different goods or services has no economic significance and cannot be used to measure price changes over time.
- c. Values are expressed in terms of a common unit of currency and are additive across different products. Values are invariant to the choice of quantity unit.

~~18.12~~18.15 In a market system, the relative prices of different goods and services should reflect both their relative costs of production and their relative utilities to purchasers, whether the latter intend to use them for production or consumption. Relative costs and relative utilities influence the rates at which sellers and buyers are prepared to exchange goods and services on markets. An aggregation of the values of different goods and services necessarily reflects the choices of which goods and services have been produced and consumed at the currently prevailing prices.

### Volume, quantity, price and unit value indices

~~18.13~~18.16 **A volume index is an average of the proportionate changes in the quantities of a specified set of goods or services between two periods of time.** The quantities compared over time must be those for homogeneous items and the resulting quantity changes for different goods and services must be weighted by their economic importance, as measured by their relative values in one or other, or both, periods. For this reason volume is a more correct and appropriate term than quantity in order to emphasize that quantities must be adjusted to reflect changes in quality.

~~18.14~~18.17 Unfortunately, it may sometimes happen, especially in the field of foreign trade statistics based on customs documentation, that the data from which price and volume indices have to be calculated are not sufficiently detailed or are otherwise inadequate for the purpose. For example, the basic information available may be limited to the total number of units of some group of products imported or exported, or their total weight, for example, the total number of pairs of shoes, or total weight of equipment of a certain type. Indices built up from information of this kind are not volume indices when the numbers, or weights, cover different items selling at different prices. They are sometimes described as “quantity indices” for this

reason. The “price” indices associated with such indices are usually described as average or “unit value” indices. Unit value indices measure the change in the average value of units that are not necessarily homogeneous and may be affected by changes in the mix of items as well as by changes in their prices. Unit value indices cannot therefore be expected to provide good measures of average price changes over time for groups of non-homogeneous items.

## 2. Inter-temporal index numbers of prices and volumes

~~18.15~~18.18 The index numbers of interest within the SNA are designed to decompose changes in value aggregates into their overall change in price and volume components. A price index can be written and calculated as a weighted average of the proportionate changes in the prices of a specified set of goods and services between two periods of time, say a reference period 0 and current period  $t$ . Similarly, a volume index can be written and calculated as a weighted average of the proportionate changes in the volumes of a specified set of goods and services between two periods of time, say a reference period 0 and current period  $t$ . There are many index number formulae differing from each other mainly in the weights which they attach to the individual price or quantity relatives and the particular form of average used, whether it is arithmetic, geometric, harmonic, etc. These alternative formulae, their properties and relative merits, are outlined in detail in the CPI and PPI manuals.

### Laspeyres and Paasche indices

~~18.16~~18.19 The two most commonly used index formulae are the Laspeyres and Paasche indices. The Laspeyres price index ( $L_p$ ) is defined as a weighted arithmetic average of the price relatives using the value shares of the reference period 0 as weights:

$$L_p = \sum_{i=1}^n \left( \frac{p_i^t}{p_i^0} \right) S_i^0 = \frac{\sum_{i=1}^n \left( \frac{p_i^t}{p_i^0} \right) p_i^0 q_i^0}{\sum_{i=1}^n p_i^0 q_i^0} \equiv \frac{\sum_{i=1}^n p_i^t q_i^0}{\sum_{i=1}^n p_i^0 q_i^0} \quad (1)$$

That is, where  $p_i^0$ ,  $q_i^0$  and  $v_i^0 = p_i^0 \times q_i^0$  are the prices, quantities and values in period 0 of  $i = 1, \dots, n$  products and  $S_i^0 = v_i^0 / \sum_{i=1}^n v_i^0$  the value shares in period 0. Similar expressions with superscripts  $t$  refer to period  $t$ .

~~18.17~~18.20 Note from (1) that the Laspeyres price index can be defined as the change in value of a basket of products whose composition is kept fixed as it was in the reference period 0. The Laspeyres volume index ( $L_Q$ ) can be similarly defined as the change in the value of a basket whose composition every period is updated but the prices of the reference period 0 are applied to the new quantities (or volumes), that is:

$$L_Q = \sum_{i=1}^n \left( \frac{q_i^t}{q_i^0} \right) S_i^0 \equiv \frac{\sum_{i=1}^n p_i^0 q_i^t}{\sum_{i=1}^n p_i^0 q_i^0} \quad (2)$$

~~18.18~~18.21 Paasche indices also exist in both price and volume forms. The Paasche index differs from the Laspeyres index in two respects. It uses a harmonic mean instead of an arithmetic average and the fixed period volumes or prices are those of the current period  $t$ . The Paasche price index is given by:

$$P_p = \left[ \sum_{i=1}^n \left( \frac{p_i^t}{p_i^0} \right)^{-1} S_i^t \right]^{-1} \equiv \frac{\sum_{i=1}^n p_i^t q_i^t}{\sum_{i=1}^n p_i^0 q_i^t} \quad (3)$$

and a Paasche volume index, with fixed current period weights or prices, by:

$$P_Q = \left[ \sum_{i=1}^n \left( \frac{q_i^t}{q_i^0} \right)^{-1} S_i^t \right]^{-1} \equiv \frac{\sum_{i=1}^n p_i^t q_i^t}{\sum_{i=1}^n p_i^0 q_i^t} \quad (4)$$

#### Deflation and volume series using Laspeyres and Paasche formulae

**18.19** **18.22** The index of the change in monetary values between two periods,  $I_v = \sum_{i=1}^n v_i^t / \sum_{i=1}^n v_i^{t-1}$ , reflects the combined effects of both price and quantity changes. When Laspeyres and Paasche indices are used, the value change will exactly decompose into a price index times a volume index only if the Laspeyres price index is matched with the Paasche volume index, that is:  $L_p \times P_Q = I_v$  or the Laspeyres volume index is matched with the Paasche price index. For example, a price index, 1.05 representing a 5 per cent change multiplied by a volume index of 1.08, an 8 per cent change, yields a value change index of 1.134, a 13.4 per cent change.

#### Laspeyres and Paasche indices reflects the combined effects

**18.20** **18.23** This relationship can be exploited whenever the total current values for both periods are known and either of a price or volume index. Suppose, for example, compilers want to derive a volume index. Laspeyres and Paasche volume indices are derived by dividing (deflating) the value change by appropriate price indices:  $L_Q = I_v / P_p$  and  $P_Q = I_v / L_p$  respectively. Note that  $L_Q$  from the right-hand side of equation (2) generates a time series of Laspeyres volume indices, for periods  $t = 1, \dots, T$  of:

$$\frac{\sum_{i=1}^n p_i^0 q_i^1}{\sum_{i=1}^n p_i^0 q_i^0}, \frac{\sum_{i=1}^n p_i^0 q_i^2}{\sum_{i=1}^n p_i^0 q_i^0}, \dots, \dots, \frac{\sum_{i=1}^n p_i^0 q_i^T}{\sum_{i=1}^n p_i^0 q_i^0} \quad (5)$$

Multiplying through the series by the common denominator  $\sum_{i=1}^n p_i^0 q_i^0$  yields the volume series:

$$\sum_{i=1}^n p_i^0 q_i^1, \sum_{i=1}^n p_i^0 q_i^2, \dots, \dots, \sum_{i=1}^n p_i^0 q_i^T \quad (6)$$

The relative movements from period to period for this series are identical with those of the associated Laspeyres volume indices given by (5), the two series differing only by a scalar that is the value in period 0.

**18.21** **18.24** Series using the prices of a base year throughout, as illustrated by (6), are easy to understand but are not best practice in national accounts if the time period T is a lengthy one over which there are changes in the structure of the economy. For example, if volume changes are measured over a 10 year period, say 2010 to 2020, at constant 2010 prices, then the volume movements in later years are based on a price configuration that is likely to have changed. A better practice is to change the weights of (rebase) the Paasche deflator in 2015 and link the resulting index to the 2014 one. The resulting volume series over the 10 year

**Formatted:** Font: (Default) +Headings CS (Times New Roman), 10 pt, Font color: Auto, Complex Script Font: +Headings CS (Times New Roman), 10 pt, Don't snap to grid, Not Highlight

period will no longer be at constant 2010 prices, but be a more representative volume index. Even better practice, resources permitting, is to form a series of annual bilateral links of constant price comparisons (see paragraphs 18.39 to 18.64). It is preferable to use the term volume series to describe such series rather than “in” or “at constant prices”.

#### *The relationship between Laspeyres and Paasche indices*

18.2218.25 Before considering other possible formulae, it is useful to establish the behaviour of Laspeyres and Paasche indices vis-à-vis each other. In general, a Laspeyres index tends to register a larger increase over the base year than a Paasche index, that is, in general:

$$\text{both } L_P > P_P \text{ and } L_Q > P_Q \quad (7)$$

It can be shown that relationship (7) holds whenever the price and quantity relatives (weighted by values) are negatively correlated, that is, as prices go up the quantities purchased go down or vice versa. Such negative correlation is to be expected for price takers, including consumers and firms purchasing intermediate inputs, who react to changes in relative prices by substituting goods and services that have become relatively less expensive for those that have become relatively more expensive. A positive correlation would be expected for price setting firms that substitute output towards goods and services that have become relatively more expensive. In such circumstances the inequalities in equation (7) would be reversed.

18.2318.26 Consumers are assumed to maximize utility, which in turn is related to combinations of goods and services purchased. Theoretical cost of living indices (COLIs) are defined as the ratio of the minimum expenditures required to enable a consumer to attain a fixed level of utility under the two sets of prices. The COLI increases if it becomes more expensive to maintain the same level of utility. A Laspeyres COLI would hold the preferences and utility fixed in the reference period and a Paasche COLI would hold them fixed in the current period.

18.2418.27 The Laspeyres price index provides an upper bound to the theoretical Laspeyres COLI. Under the COLI, consumers can substitute products that have become relatively less expensive for ones that have become relatively more expensive to obtain the same level of utility, whereas the fixed basket Laspeyres index does not allow such substitution. Similarly, the Paasche index can be shown to provide a lower bound to the theoretical Paasche COLI.

#### **Other index number formulae**

18.2518.28 Because different formulae give different results, a consideration of alternative approaches to choosing among them is needed and this in turn gives rise to a consideration of further index number formulae.

18.2618.29 It is apparent from the Laspeyres and Paasche price indices in equations (1) and (3) that both indices hold the basket of quantities fixed. The formulae differ in that Laspeyres holds the basket fixed in the reference period and Paasche in the current period. If the objective is simply to measure the price change between the two periods considered in isolation, there is no reason to prefer the basket of the earlier period to that of the later period, or vice versa. Both baskets are equally justifiable from a conceptual point of view. Thus, although they yield different results, neither formula can be judged superior to the other.

18.2718.30 A compromise solution for the price index is to use a formula that makes symmetric use of the base and current period information on quantities. The Fisher index can be shown to be the most suitable in this regard. (For an explanation of why this is so, see chapter 15 of the PPI manual.) The Fisher index (F) is defined as the geometric mean of the Laspeyres and Paasche indices, that is, for price and quantity indices respectively:

$$F_P = \{L_P \cdot P_P\}^{1/2} \text{ and } F_Q = \{L_Q \cdot P_Q\}^{1/2} \quad (8)$$

**Formatted:** Font: (Default) +Headings CS (Times New Roman), 10 pt, Font color: Auto, Complex Script Font: +Headings CS (Times New Roman), 10 pt, Don't snap to grid, Highlight

**Formatted:** Font: (Default) +Headings CS (Times New Roman), 10 pt, Font color: Auto, Complex Script Font: +Headings CS (Times New Roman), 10 pt, Don't snap to grid, Highlight

~~18.28~~18.31 Economic theory postulates indifference curves that show how consumers would alter their expenditure patterns in response to changes in prices. Unless the utility functions the indifference curves represent are similar in periods 0 and t, a Laspeyres and a Paasche index for this period will each refer to a differently shaped utility function. In general, the Laspeyres index will provide an upper bound to its underlying utility function while the Paasche index will give a lower bound to its underlying utility function but the two utility functions will be different.

~~18.29~~18.32 In order to resolve this dilemma, a series of indices called superlative indices have been derived that relate to utility functions that adapt over time to the changes in quantities brought about by changes in prices. The Fisher index is one example of a superlative index; a Törnqvist index is another example. A Törnqvist index is the geometric average of the price relatives weighted by average expenditure shares in two periods. Thus the Törnqvist price and volume indices are defined as:

$$T_P = \prod_{i=1}^n \left( \frac{p_i^t}{p_i^0} \right)^{\frac{(s_i^0 + s_i^t)/2}{2}} \text{ and } T_Q = \prod_{i=1}^n \left( \frac{q_i^t}{q_i^0} \right)^{\frac{(s_i^0 + s_i^t)/2}{2}} \quad (9)$$

Both Fisher and Törnqvist indices utilize and attach equal importance to information on the value shares in both periods for weighting purposes. For this reason they may be expected to lie between the bounds of Laspeyres and Paasche indices, as is desired. The difference between the numerical values of the Törnqvist and Fisher indices and other such symmetric indices is likely to be very small. Neither Törnqvist or Fisher volume indices use the prices of a specific single period. The term “at constant prices” is a misnomer for such series; the correct term is a series in volume terms.

~~18.30~~18.33 The above analysis has been from the consumer’s or purchaser’s perspective. Economic theory also defines Laspeyres and Paasche bounds from the producer’s perspective. Revenue maximizing producers are expected to increase the relative quantities they produce in response to increases in relative prices. The resulting Laspeyres/Paasche bounds are the reverse of those described above, as quantities produced are substituted towards commodities with above average changes in prices. But the implication for removing substitution bias by the use of Törnqvist and Fisher indices still holds.

### Desirable index number characteristics

~~18.34~~18.34 There are two frequently quoted characteristics that it is felt index numbers for deflating national accounts should satisfy. These are the “time reversal” and “factor reversal” tests. The time reversal test requires that the index for period t compared with period 0 should be the reciprocal of that for period 0 compared with t. The factor reversal test requires that the product of the price index and the volume index should be equal to the proportionate change in the current values. It follows from the discussion in the preceding section that Laspeyres and Paasche indices on their own do not pass either of these tests. However, it follows from the definitions of Fisher indices in (8) that the Fisher index does pass these tests.

~~18.32~~18.35 The Fisher index therefore has a number of attractions that have led it to be extensively used in general economic statistics. Indeed, Fisher described his index as “ideal”. However, the Fisher index requires both reference and current period information for weights, which may affect the timeliness of the index, nor is it as easy to understand as Laspeyres or Paasche indices.

~~18.33~~18.36 The PPI manual provides in chapters 15, 16 and 17 an extensive account of the various approaches to choosing among index numbers. Also included in chapter 16 is the stochastic approach that favours the Törnqvist index. What is apparent from this extensive body of work is that all three approaches favour the Fisher index; that superlative indices such as the Fisher and Törnqvist indices produce very similar results and can all be justified from the economic theoretical approach and that the difference between superlative indices and the Laspeyres or Paasche indices, or their spread, is due to substitution bias.

### Index numbers in practice

~~18.34~~18.37 The Laspeyres price index in equation (1) has the same price and weight reference period 0. In practice, especially for CPIs where timeliness is of the essence, the price reference period 0 differs from the earlier weight reference period, say  $b$ , since it takes time to compile the results from the survey of households, establishments and other sources for the weights to use in the index. The Laspeyres index given by the first expression in equation (1) may have as its weights  $S_i^b$  instead of  $S_i^0$ . This index is a Young index and, like the Laspeyres index, has the undesirable property of failing the time reversal test.

~~18.35~~18.38 Statistical offices often try to overcome this by adjusting the value shares used as weights by the changes in prices between  $b$  and 0 to form a Lowe index given by:

$$L_{oweP} = \frac{\sum_{i=1}^n \left( \frac{p_i^t}{p_i^0} \right) \left( \frac{p_i^0}{p_i^b} \right) v_i^b}{\sum_{i=0}^n v_i^b \left( \frac{p_i^0}{p_i^b} \right)} \equiv \frac{\sum_{i=1}^n p_i^t q_i^b}{\sum_{i=1}^n p_i^0 q_i^b} \quad (10)$$

### 3. Chain indices

#### The rebasing and linking of indices

~~18.36~~18.39 As noted in the previous section, over time the pattern of relative prices in the base period tends to become progressively less relevant to the economic situations of later periods to the point where it becomes unacceptable to continue using them to measure volume changes from one period to the next. It is then necessary to update the weights. With long time series, it is as inappropriate to use the most current weights for a date long in the past as it is to use the weights from a long time in the past for the current period. It is therefore necessary to link the old series to the new reweighted series by multiplication. This is a simple numerical operation requiring estimates for an overlapping period of the index or series calculated using both the old and new weights.

~~18.37~~18.40 The linking calculation can be undertaken in a number of ways. The current index on the new weights can be multiplied by a linking coefficient of the old to new index to convert the new index to the old index reference period. Alternatively, the index may have its reference period changed at the time of the introduction of new weights and the old index may be revised by dividing it by the linking coefficient. The process of linking an old series and a new one by means of a link for an overlap period is referred to as chaining. [Numerical examples of linking and other chain index calculations are available in chapter 8 of Quarterly National Accounts Manual.](#)

~~18.38~~18.41 Whether the chaining is done so as to preserve the earlier reference period in the new series or to change the reference period of the old series to the new one, the calculations have to be undertaken at each level of aggregation. Each component as well as each aggregate has to be linked individually because of non-additivity.

#### Chaining each period

~~18.39~~18.42 The more frequently weights are updated the more representative will the resulting price or volume series be. Annual chain indices result from compiling annual indices over two consecutive years each with updated weights. These “links” are combined by successive multiplication to form a series. In order to understand the properties and behaviour of chain indices in general, it is necessary to establish first how chain Laspeyres and Paasche indices behave in comparison with fixed base indices.

#### Chain Laspeyres and Paasche indices

~~18.40~~18.43 A chain Laspeyres volume index,  $L_Q$ , connecting periods 0 and  $t$ , is an index of the following form:

$$L_Q = \frac{\sum_{i=1}^n p_i^0 q_i^1}{\sum_{i=1}^n p_i^0 q_i^0} \times \frac{\sum_{i=1}^n p_i^1 q_i^2}{\sum_{i=1}^n p_i^1 q_i^1} \times \dots \times \frac{\sum_{i=1}^n p_i^{t-1} q_i^t}{\sum_{i=1}^n p_i^{t-1} q_i^{t-1}} \quad (11a)$$

The corresponding chain Paasche volume index, PQ, has the following form:

$$P_Q = \frac{\sum_{i=1}^n p_i^1 q_i^1}{\sum_{i=1}^n p_i^0 q_i^0} \times \frac{\sum_{i=1}^n p_i^2 q_i^2}{\sum_{i=1}^n p_i^1 q_i^1} \times \dots \times \frac{\sum_{i=1}^n p_i^t q_i^t}{\sum_{i=1}^n p_i^{t-1} q_i^{t-1}} \quad (11b)$$

Laspeyres and Paasche price indices are obtained by interchanging the p's and q's in the expressions for the volume indices.

~~18.44~~18.44 In general, if fixed base indices are replaced by chain indices, the index number spread between Laspeyres and Paasche is likely to be greatly reduced. Chain indices thus have an advantage over fixed base ones. The relationship between a fixed base index and the corresponding chain index is not always the same, however, as it depends upon the paths followed by individual prices and quantities over time.

~~18.42~~18.45 If individual prices and quantities tend to increase or decrease steadily over time it can be shown that chaining will significantly reduce the index number spread, possibly almost eliminating it. Chapters 9 and 19 of the PPI manual provides illustrative examples and chapter 15 explains the theory underlying these findings

~~18.43~~18.46 On the other hand, if individual prices and quantities fluctuate so that the relative price and quantity changes occurring in earlier periods are reversed in later periods, chaining will produce worse results ([in comparison with the Fisher index](#)) than a simple index.

~~18.44~~18.47 On balance, situations favourable to the use of chain Laspeyres and Paasche indices over time seem more likely than those that are unfavourable. The underlying economic forces that are responsible for the observed long-term changes in relative prices and quantities, such as technological progress and increasing incomes, do not often go into reverse. Hence, it is generally recommended that annual indices be chained. The price and volume components of monthly and quarterly data are usually subject to much greater variation than their annual counterparts due to seasonality and short-term irregularities. Therefore, the advantages of chaining at these higher frequencies are less and chaining should definitely not be applied to seasonal data that are not adjusted for seasonal fluctuations.

#### *Annually chained quarterly Laspeyres-type indices*

~~18.45~~18.48 Quarterly chain indices can be constructed that use annual weights rather than quarterly weights. Consider a quarterly Laspeyres-type volume index that measures the volume change from the average of year  $y-1$  to quarter  $c$  in year  $y$ .

$$L_Q^{(y-1) \rightarrow (c,y)} = \frac{\sum_i P_i^{y-1} q_i^{c,y}}{\sum_i P_i^{y-1} Q_i^{y-1}} = \sum_i \frac{q_i^{c,y}}{Q_i^{y-1}} s_i^{y-1} \quad (12a)$$

The upper case letters  $P$  and  $Q$  denote average quarterly values over a year, while  $p$  and  $q$  denote specific quarterly values. The superscripts denote the year ( $y$ ) and quarter ( $c$ ).  $P^{y-1}$  denotes the average price of item  $i$  in year  $y-1$

and  $p_{c,y-1}$  denotes the price of item  $i$  in quarter  $c$  of year  $y-1$

and  $s^{y-1}$  is the base period value share, that is the share of item  $i$  in the total value in year  $y-1$ .

Thus:

$$P_i^{y-1} = \frac{\sum_c p_i^{c,y-1} q_i^{c,y-1}}{\sum_c q_i^{c,y-1}}; \quad Q_i^{y-1} = \frac{\sum_c q_i^{c,y-1}}{4}; \text{ and}$$

$$S_i^{y-1} = \frac{P_i^{y-1} Q_i^{y-1}}{\sum_c p_i^{c,y-1} q_i^{c,y-1}} = \frac{\sum_c p_i^{c,y-1} q_i^{c,y-1}}{\sum_c \sum_c p_i^{c,y-1} q_i^{c,y-1}} \quad (12b)$$

**18.4618.49** The quarterly Laspeyres-type volume indices can then be chained together with annual links. One of two alternative techniques for the annual chaining of quarterly data is usually applied, annual overlaps and one-quarter overlaps. In addition to these two conventional chaining techniques, a third technique sometimes is used based on changes from the same period in the previous year (the “over-the-year technique”). While in many cases all three techniques give similar results, in situations with strong changes in relative quantities and relative prices, the over-the-year technique can result in distorted seasonal patterns in the chained series. While standard price statistics compilation exclusively uses the one-quarter overlap technique, the annual overlap technique may be more practical for Laspeyres-type volume measures in the national accounts because it results in data that aggregate exactly to the corresponding direct annual index. In contrast, the one quarter overlap technique and the over-the-year technique do not result in data that aggregate exactly to the corresponding direct annual index. The one-quarter overlap provides the smoothest transition between each link in contrast to the annual overlap technique, which often introduces a step between each link, that is, between the fourth quarter of one year and the first quarter of the following year.

**18.4718.50** The technique of using annual overlaps implies compiling estimates for each quarter at the weighted annual average prices of the previous year, with subsequent linking using the corresponding annual data to provide linking factors to scale the quarterly data upward or downward. The technique of one-quarter overlaps requires compiling estimates for the overlap quarter at the weighted annual average prices of the current year in addition to estimates at the average prices of the previous year. The ratio between the estimates for the linking quarter at the average prices of the current year and at the average prices of the previous year then provides the linking factor to scale the quarterly data up or down. The over-the-year technique requires compiling estimates for each quarter at the weighted annual average prices of the current year in addition to estimates at the average prices of the previous year. The year-on-year changes in these volume series are then used to extrapolate the quarterly volume series of the chosen reference period.

**18.4818.51** Discrepancies between an annual chain volume series and the sum of the four quarters of an annually chained quarterly volume series derived using the one-quarter overlap technique can accumulate over time. Hence, quarterly chain volume series derived this way are usually benchmarked to the corresponding annual chain volume series using a procedure that minimizes the disturbance to the quarterly volume series whilst achieving consistency with the annual chain volume series. There is discussion on this in chapter 6 of Quarterly National Accounts [Manual](#).

**18.4918.52** If annual volume series are derived from data balanced in a supply and use table expressed in the prices of the previous year as recommended in section C, then it is standard practice to benchmark quarterly data to the corresponding annual balanced estimates. The benchmarking eliminates all discrepancies between the quarterly and annual chain volume series, including those arising from the use of the one-quarter overlap technique.

**18.5018.53** To conclude, chaining using the one-quarter overlap technique combined with benchmarking to remove any resulting discrepancies between the quarterly and annual data gives the best result. In many circumstances, however, the annual overlap technique may give similar results. The over-the-year technique should be avoided.

#### *Chain Laspeyres or chain superlative indices?*

**18.5118.54** As explained earlier, the index number spread between Laspeyres and Paasche indices may be greatly reduced by chaining when prices and quantities move smoothly over time. In such circumstances the choice of index number formula assumes less significance as all relevant index numbers lie within the bounds of the Laspeyres and Paasche indices. Nevertheless, there may still be some advantages to be gained by choosing an index for chaining, such as the Fisher or Törnqvist, that treats both periods being compared

symmetrically.

**18.55** Such indices are likely to approximate more closely the theoretical indices based on underlying utility or production functions even though chaining may reduce the extent of their advantages over their Laspeyres or Paasche counterparts in this respect. A chain symmetric index, such as Fisher or Törnqvist, is also likely to perform better when there are fluctuations in prices and quantities. Chain Laspeyres indices, however, do not require current period data for weights and thus may lead to more timely estimates. Retrospective studies of the difference in national accounts estimates from using chain Laspeyres as against chain Fisher or Törnqvist can help in determining the advantage of using the latter formulae.

#### *Annually chained quarterly Fisher-type indices*

**18.56** Just as it is possible to derive annually chained Laspeyres-type quarterly indices, so it is possible to derive annually chained Fisher-type quarterly indices. For each pair of consecutive years Laspeyres-type and Paasche-type quarterly indices are constructed for the last two quarters of the first year, year  $y-1$  and the first two quarters of the second year, year  $y$ . The Paasche-type quarterly indices are constructed as backward-looking Laspeyres-type quarterly indices and then inverted. This is done to ensure that the Fisher-type quarterly indices are derived symmetrically. In the forward-looking Laspeyres-type indices the annual value shares relate to the first of the two years, whereas in the backward-looking Laspeyres-type indices the annual value shares relate to the second of the two years.

$$L_q^{(\overline{y-1}) \rightarrow c} = \frac{\sum_i p_i^{y-1} q_i^c}{\sum_i p_i^{y-1} q_i^{y-1}} = \sum_i \frac{q_i^c}{q_i^{y-1}} S_i^{y-1} \quad (13)$$

$$P_q^{\overline{y} \rightarrow c} = \left[ L_q^{\overline{y} \rightarrow c} \right]^{-1} \quad (14a)$$

$$L_q^{\overline{y} \rightarrow c} = \frac{\sum_i p_i^y q_i^c}{\sum_i p_i^y q_i^y} = \sum_i \frac{q_i^c}{q_i^y} S_i^y \quad (14b)$$

and  $q_i^c$  is the quantity of item  $i$  in quarter  $c$  in the second two quarters of year  $y-1$  or the first two quarters of year  $y$ .

**18.57** For each of the four quarters a Fisher-type index is derived as the geometric mean of the corresponding Laspeyres-type and Paasche-type indices. Consecutive spans of four quarters can then be linked using the one-quarter overlap technique. The resulting annually chained Fisher-type quarterly indices need to be benchmarked to annual chain Fisher indices to achieve consistency with the annual estimates.

**18.58** A difficulty arises at the end of the series because it is not possible to construct Paasche-type quarterly indices that use annual weights for the current year, at least using actual observed data. One solution is to construct "true" quarterly chain Fisher indices for the latest year or two and use these to extrapolate the annually chained Fisher-type indices. But this should only be done using seasonally adjusted data. As long as the irregular variation in quarterly price and volume relativities is not very great, quarterly chain Fisher indices of seasonally adjusted data can be expected to produce satisfactory results in most circumstances.

#### *Chaining and data coverage*

**18.59** One major practical problem in the construction of index numbers is the fact that products are continually disappearing from markets to be replaced by new products as a result of technological progress, new discoveries, changes in tastes and fashions, and catastrophes of one kind or another. Price and volume indices are compiled by comparing the prices or quantities of goods of the same characteristics or quality

**Formatted:** Font: (Default) +Headings CS (Times New Roman), 10 pt, Font color: Auto, Complex Script Font: +Headings CS (Times New Roman), 10 pt, Don't snap to grid, Not Highlight

(that is, homogenous goods) over time. This is not easy in product areas such as personal computers where quality changes rapidly.

~~18.57~~18.60 Chaining helps ameliorate the problems of such constant quality comparisons since the likelihood of an overlap of a product in two consecutive price periods is almost bound to be greatest and the chain indices can accommodate the changes in weight that accompany a new and a disappearing product.

### *Additivity and chaining*

~~18.58~~18.61 An aggregate is defined as the sum of its components. Additivity in a national accounts context requires this identity to be preserved for a volume series. Although desirable from an accounting viewpoint, additivity is actually a very restrictive property. Laspeyres volume indices are the only index number formulae considered here that are additive.

~~18.59~~18.62 A single link in a chain index is sufficient to destroy additivity even when additive indices, such as Laspeyres volume indices, are linked together. Consequently, if chain volume indices are converted into time series of values by using the indices to extrapolate the values of the base period, the index components may fail to add to aggregates in later periods. A perverse form of non-additivity can occur when the chain index for the aggregate lies outside the range spanned by the chain indices for its components, a result that may be regarded as intuitively unacceptable by many users. Whether published in monetary terms or indices, it is advisable to inform users via a footnote or other meta-data that chain volume series are not additive.

~~18.60~~18.63 There is a general tendency for the discrepancies from chaining to become larger the further a period is away from the reference year. If the reference year is chosen to be near the end of the series then the discrepancies will be relatively small for the latest quarters. Indeed, if the chain Laspeyres formula is used and if the reference year is chosen to coincide with the latest base year then the quarters following the reference year are additive. Another advantage of having the reference year near the end of chain volume series is that when they are expressed as monetary values their magnitudes do not differ greatly from the current values for the latest periods if price change is occurring at a modest rate. Maintaining this situation requires rereferencing the series every year when a new link is added to the chain and this entails revising the chain volume series for their entire lengths. Note that rereferencing entails revising levels but not growth rates.

~~18.61~~18.64 Although additivity may be preserved by never undertaking a weight change this advantage is significantly outweighed by the disadvantage of increasing irrelevance of the weights in use. Rates of change for subperiods of a series, including annual rates, can be usefully phrased in terms of contributions to change, as explained below.

### **Variables that change sign**

~~18.62~~18.65 Index number formulae are generally not applicable to time series that can take positive, negative and zero values. Nevertheless, there are ways of deriving pseudo chain volume series expressed in terms of monetary values in such cases. The most commonly used approach is to identify two associated time series that take only positive values and are such that when differenced yield the target series. An example is the stock of inventories at the start and end of the period as opposed to the change during the period. Chain volume series are not additive and so it is evident that this is an imperfect method since by construction an additive relationship is produced. It follows that the series to be differenced should be as closely aligned in terms of price and volume composition as possible with the target series. Hence, a chain volume series of changes in inventories is derived as a chain volume series of closing inventories less a chain volume series of opening inventories. Sometimes public gross fixed capital formation can take negative values as a result of the sale of assets to the private sector, in which case the chain volume series of acquisitions and sales could be differenced.

### **Contributions to growth**

**18.63** **18.66** When the Laspeyres formula is used and the base year and reference year coincide, the resulting volumes are additive in subsequent periods and the contribution by a component  $I_i$  to the growth of an aggregate, such as GDP, between two periods  $(t-n)$  and  $t$  can be obtained readily as follows:

$$\% \Delta_i^{(t-n) \rightarrow t} = \frac{100(I_i^t - I_i^{t-n})}{\sum_i I_i^{t-n}} \quad (15)$$

When chain volume series are derived using either the Laspeyres formula for annual indices or the annual chaining of Laspeyres-type quarterly indices, then year-to-year or quarter-to-quarter contributions to growth can be derived easily using data expressed in the prices of the previous year prior to chaining. Such data are additive and so equation (15) can be used with  $n=1$ . If contributions to growth are not published by the national statistical office, the user can estimate them. Assuming the one-quarter overlap technique has been used, the formula for calculating the contribution to the percentage change from period  $t-1$  to period  $t$  is:

$$\% \Delta_i^{(t-1) \rightarrow t} = \frac{100(I_i^t - I_i^{t-1})S_i^{t-1}}{\sum_i I_i^{t-1}S_i^{t-1}} \quad (16)$$

where the  $s$  are the shares of the items in the total as in equations (12).

#### 4. Causes of price variation

##### Price variation due to quality differences

**18.64** **18.67** In general, most types of goods or services, whether simple food products such as potatoes or high technology products such as computers, are available on the market in many different qualities whose physical characteristics differ from each other. For example, potatoes may be old or new, red or white, washed or unwashed, loose or pre-packed, graded or ungraded. Consumers recognize and appreciate the differences and are prepared to pay different prices. For some goods and services, such as personal computers and telecommunication services, there is a rapid turnover in the highly differentiated varieties and this, as considered below, creates severe problems for the measurement of price changes.

**18.65** **18.68** The same generic term, such as potato, computer or transportation is used to describe goods and services that differ from each other in their price-determining characteristics. The price or quantity of a good or service of one quality cannot be directly compared to that of a different quality. Different qualities have to be treated in exactly the same way as different kinds of goods or services.

**18.66** **18.69** Differences in quality may be attributable to differences in the physical characteristics of the goods or services concerned and be easily recognized, but not all differences in quality are of this kind. Goods or services delivered in different locations, or at different times, such as seasonal fruits and vegetables, must be treated as different qualities even if they are otherwise physically identical. The conditions of sale, or circumstances or environment in which the goods or services are supplied or delivered can make an important contribution to differences in quality. For example, a durable good sold with a guarantee, or free after-sales service is higher quality than the same good sold without guarantee or service. The same goods or services sold by different kinds of retailers, such as local shops, specialist shops, department stores or supermarkets may have to be treated as different qualities.

**18.67** **18.70** It is generally assumed in economic analysis that whenever a difference in price is found between two goods and services that appear to be physically identical there must be some other factor, such as location, timing or conditions of sale, that is introducing a difference in quality. Otherwise, it can be argued that the difference could not persist, as rational purchasers would always buy lower priced items and no sales would take place at higher prices.

**18.68** **18.71** When there is price variation for the same quality of good or service, the price relatives used for index number calculation should be defined as the ratio of the weighted average price of that good or service in the two periods, the weights being the relative quantities sold at each price. Suppose, for example, that a

certain quantity of a particular good or service is sold at a lower price to a particular category of purchaser without any difference whatsoever in the nature of the good or service offered, location, timing or conditions of sale, or other factors. A subsequent decrease in the proportion sold at the lower price raises the average price paid by purchasers for quantities of a good or service whose quality is the same and remains unchanged, by assumption. It also raises the average price received by the seller without any change in quality. This must be recorded as a price and not a volume increase.

### Price variation without quality differences

~~18.69~~18.72 Nevertheless, it must be questioned whether the existence of observed price differences always implies corresponding differences in quality. There are strong assumptions underlying the standard argument which are seldom made explicit and are often not satisfied in practice: for example, that purchasers are well informed and that they are free to choose between goods and services offered at different prices.

~~18.70~~18.73 In the first place, purchasers may not be properly informed about existing price differences and may therefore inadvertently buy at higher prices. While they may be expected to search for the lowest prices, costs are incurred in the process. Given the uncertainty and lack of information, the potential costs incurred by searching for outlets in which there is only a possibility that the same goods and services may be sold at lower prices may be greater than the potential savings, so that a rational purchaser may be prepared to accept the risk that he or she may not be buying at the lowest price. Situations in which the individual buyers or sellers negotiate, or bargain over prices, provide further examples in which purchasers may inadvertently buy at a higher price than may be found elsewhere. On the other hand, the difference between the average price of a good purchased in a market or bazaar in which individual purchasers bargain over the price and the price of the same good sold in a different type of retail outlet, such as a department store, should normally be treated as reflecting differences in quality attributable to the differing conditions under which the goods are sold.

### Price discrimination

~~18.71~~18.74 Secondly, purchasers may not be free to choose the price at which they purchase because the seller may be in a position to charge different prices to different categories of purchasers for identical goods and services sold under exactly the same circumstances, in other words, to practise price discrimination. Economic theory shows that sellers have an incentive to practise price discrimination as it enables them to increase their revenues and profits. However, it is difficult to discriminate when purchasers can retrade amongst themselves, that is, when purchasers buying at the lowest prices can resell the goods to other purchasers. While most goods can be retraded, it is usually impossible to retrade services, and for this reason price discrimination is extensively practised in industries such as transportation, finance, business services, health, education, etc., in most countries. Lower prices are typically charged to purchasers with low incomes, or low average incomes, such as pensioners or students. When governments practise or encourage the practice of price discrimination it is usually justified on welfare grounds, but market producers also have reasons to discriminate in favour of households with low incomes as this may enable them to increase their profits. Thus, when different prices are charged to different consumers it is essential to establish whether or not there are in fact any quality differences associated with the lower prices. For example, if senior citizens, students or schoolchildren are charged lower fares for travelling on planes, trains or buses, at whatever time they choose to travel, this must be treated as pure price discrimination. However, if they are charged lower fares on condition that they travel only at certain times, typically off-peak times, they are being offered lower quality transportation.

### The existence of parallel markets

~~18.72~~18.75 Thirdly, buyers may be unable to buy as much as they would like at a lower price because there is insufficient supply available at that price. This situation typically occurs when there are two parallel markets. There may be a primary, or official, market in which the quantities sold, and the prices at which they are sold, are subject to government or official control, while there may be a secondary market, either a free

market or unofficial market, whose existence may or may not be recognized officially. If the quantities available at the price set in the official market are limited there may be excess demand so that supplies have to be allocated by rationing or some form of queuing. As a result, the price on the secondary or unofficial market will tend to be higher. It is also possible, but less likely, that lower prices are charged on the secondary or unofficial market, perhaps because the payment of taxes on products can be evaded in such a market.

~~18.73~~18.76 \_\_\_\_\_ For the three reasons just given, lack of information, price discrimination or the existence of parallel markets, identical goods or services may sometimes be sold to different purchasers at different prices. Thus, the existence of different prices does not always reflect corresponding differences in the qualities of the goods or services sold.

~~18.74~~18.77 \_\_\_\_\_ When there is price variation for the same quality of good or service, the price relatives used for index number calculation should be defined as the ratio of the weighted average price of that good or service in the two periods, the weights being the relative quantities sold at each price. Suppose, for example, that a certain quantity of a particular good or service is sold at a lower price to a particular category of purchaser without any difference whatsoever in the nature of the good or service offered, location, timing or conditions of sale, or other factors. A subsequent decrease in the proportion sold at the lower price raises the average price paid by purchasers for quantities of a good or service whose quality is the same and remains unchanged, by assumption. It also raises the average price received by the seller without any change in quality. This must be recorded as a price and not a volume increase.

~~18.75~~18.78 \_\_\_\_\_ It may be difficult to distinguish genuine price discrimination from situations in which the different prices reflect differences in quality. Nevertheless, there may be situations in which large producers (especially large service producers in fields such as transportation, education or health) are able to make the distinction and provide the necessary information. If there is doubt as to whether the price differences constitute price discrimination, it seems preferable to assume that they reflect quality differences, as they have always been assumed to do so in the past.

## 5. The measurement of changes in quality over time

~~18.76~~18.79 \_\_\_\_\_ Goods and services and the conditions under which they are marketed are continually changing over time, with some goods or services disappearing from the market and new qualities or new goods or services replacing them. National accountants use disaggregated price indices to deflate changes in consumption, production and investment values as the principle means of determining volume changes in such aggregates. Deficiencies in price indices carry over to estimates of volume changes. For example, estimates of price indices for computers that do not fully incorporate the increases in quality over time will overstate price changes and understate volume changes. National accountants need to be aware of the extent and nature of methods used by price compilers to take account of such quality changes, if they are to use them properly as deflators. This in turn requires that price compilers keep explanatory notes on such methods used, a policy advocated by [chapter 7 of the CPI manual](#) and chapter 8 of the PPI manual.

~~18.77~~18.80 \_\_\_\_\_ There are, of course, costs associated with implementing quality adjustment procedures tailored to the specific product groups. What is important for national accountants and price index compilers to appreciate is that quality change is an increasing feature of product markets. The default procedures of dealing with quality change, specifically by treating all replacements as comparable, or dropping varieties from the sample if missing, implicitly incorporate valuations of quality differences. Such valuations are unlikely to be appropriate and improvements can and should be made.

~~18.78~~18.81 \_\_\_\_\_ An unfortunate common procedure to deal with missing values is to carry forward the price from the previous period into the current period. This may well bias the index and is strongly discouraged.

~~18.79~~18.82 \_\_\_\_\_ A brief overview of some of the more common techniques follows. More extensive discussion can be found in all the three price manuals, those for CPI, PPI and XMPI. The techniques can be divided into those that are direct or explicit methods and those that are indirect or implicit.

### Direct methods

~~18.80~~18.83 In principle, the price relatives that enter into the calculation of inter-temporal price indices should measure pure price changes by comparing the prices of a representative sample of identical goods and services in different time periods. This is called the matched-models method. Price index compilers maintain detailed product descriptions of the items being priced in successive periods to ensure proper matching. When a model is missing because it is obsolete, a problem of quality adjustment arises. A number of methods can be used to take account of the quality change in order to continue the series.

~~18.84~~18.84 One possibility is to use the estimated relative costs of production as the basis for estimates of their relative prices and hence their relative qualities. It may often be feasible for producers to provide such estimates. If, however, the new quality feature was available as an option in the previous period, but now is a standard feature, the estimate of the valuation of the quality change may be based on the (relative) price of this option.

~~18.82~~18.85 An extension of the costs of production approach is known as model pricing. It is often applied to products made to order. A particular case in point is measuring building costs. The characteristics of buildings and other structures are so variable that it may be almost impossible to find identical buildings and structures being produced in successive periods of time. In these circumstances, a small number of hypothetical and relatively simple standard buildings and structures may be specified and their prices estimated in each of the periods. The specifications of these standard buildings or structures are chosen on the advice of construction experts who are also asked to estimate what their prices would be in each of the periods. Model pricing for services is described in Methodological Guide for Developing Producer Price Indices for Services. (Eurostat and the Organisation for Economic Co-operation and Development, 2005)

### Hedonics

~~18.83~~18.86 A more general and powerful method of dealing with changes in quality is to make use of estimates from hedonic regression equations. Hedonic regression equations relate the observed market prices of different models to ~~certain~~ measurable price-determining characteristics. Provided sufficiently many differentiated models are on sale at the same time, the estimated regression equation can be used to determine by how much prices vary in relation to each of the characteristics or to predict the prices of models with different mixes of characteristics that are not actually on sale in the period in question.

~~18.84~~18.87 Hedonic regression equations have been estimated for high technology goods such as computers and electronic goods and for services such as air transportation. The technique has also been used for housing by regressing house prices (or rents) on characteristics such as area of floor space, number of rooms or location. The method has been used not only for inter-temporal price measurements ~~for goods~~ but also for services in the index. ~~The assumptions behind such imputations are less soundly based than those behind the more targeted imputation. In either case, items subject to quality change tend to be atypical and unrepresentative, so that assuming that their prices change at the same rate as for goods or services whose characteristics do not change is questionable.~~

~~18.85~~18.88 The hedonic approach is most useful when the market does not directly reveal the price and quality characteristics, but they can be inferred from prices of many varieties with different characteristics. To implement the hedonic approach, one needs to compile a data set consisting of prices and characteristics for many varieties. A sufficiently large data set with substantial variability in the mix of characteristics allows the hedonic regression to produce estimates of the implicit prices of the characteristics. For example, extensive data on the prices and characteristics of varieties of consumer goods can often be collected from the websites of retailers with relative ease.

~~18.86~~18.89 The hedonic regression is usually conducted using a semilogarithmic form. That is, the logarithm of the price of a variety in the sample is regressed against a standard set of characteristics given by

$$\ln p = \beta_0 + z_1 \beta_1 + z_2 \beta_2 + z_3 \beta_3 + \dots + z_n \beta_n + \varepsilon$$

where  $\varepsilon$  is an error term that is assumed to satisfy the standard set of assumptions used in regression analysis. For the semilogarithmic form, logarithms are taken only of the left-hand side variable (that is, *Price*). Each of the characteristics,  $z$ , enters the equation without taking logarithm (though it is possible for the analyst to take logarithms if it would provide a better fit). The semilogarithmic form allows the use of indicator variables (or dummy variables) that take a value of one if the variety has a feature and zero if it does not.

**Commented [ED2]:** This subsection has been slightly expanded to provide a better introduction to this topic which is of growing importance. The main source of new material is *Consumer Price Index Manual: Concepts and Methods* (2020 edition), paras. 6.136-6.223.

The coefficients,  $\beta$ , can be interpreted as the percentage or proportional change in the price associated with a one-unit change in the characteristic.

18.8718.90 There are two ways in which hedonic quality adjustments can be applied to the estimation of price indexes. The first way is described as “patching” and is a way of dealing with noncomparable product substitutions in the matched-model method. It involves making an explicit quality adjustment to the price of an old variety that has dropped out of a sample to make it comparable to the new variety that has replaced it. The second way is a more comprehensive process that is used for rapidly changing products that are experiencing substantial changes in quality within relatively short periods. That process, known as hedonic price indices, requires a sample to be drawn in each period and controls for quality differences in the hedonic regression. Hedonic price indices are discussed in the *Consumer Price Index Manual: Concepts and Methods*, 2020 edition, 6.136–6.223.

Table 18.1 Hedonic Regression Imputation of New Variety's Price

Variety/ Period	$t$	$t + 1$	$t + 2$	$t + 3$	$t + 4$
$l$	$p_l^t$	$p_l^{t+1}$	$p_l^{t+2}$	$p_l^{t+3}$	$p_l^{t+4}$
$m$	$p_m^t$	$p_m^{t+1}$	$p_m^{t+2}$		
$n$			$\tilde{p}_n^{t+2}$	$p_n^{t+3}$	$p_n^{t+4}$

18.8818.91 Consider the sample for a matched model index in Table 18.1 where variety  $l$  is available in all periods, the “old” variety  $m$  is only available in periods  $t$ ,  $t + 1$ , and  $t + 2$ , and the replacement variety  $n$  is only available in periods  $t + 3$  and  $t + 4$ . Variety  $m$ 's replacement  $n$  is noncomparable, so  $p_m^{t+2}$  cannot be directly compared with  $p_n^{t+3}$ . The hedonic imputation approach would predict the price of variety  $n$  in period  $t + 2$  using a hedonic regression estimated in period  $t + 2$  and the characteristics of the new variety  $n$  from period  $t + 3$ . Alternatively, if data are not available to support estimation of regression coefficients each period, an alternative approach would be the hedonic quality-adjustment method.

18.8918.92 The compilers of price indices should consider the limitations and challenges of implementing the hedonic approach:

- The hedonic approach requires staff to possess sufficient expertise and understanding of regression methodology to interpret the results and diagnostic statistics of the models.
- The estimated coefficients require regular updating, which entails updating of the data sets used to prepare estimates and updating of the estimates themselves.
- The sample of prices and characteristics used for the hedonic adjustments need to be representative of markets during the period that the adjustments are applied.
- The functional form and choice of variables to include in the model need to be carefully considered.
- The resources required for gathering and maintaining the data for estimating the hedonic regressions should be considered.
- The staff resources required for devising the specification, estimation and validation of the hedonic model and its regular updating should be considered.

## Indirect methods

18.9018.93 When the two qualities are not produced and sold on the market at the same time it becomes necessary to resort to indirect methods of quantifying the change in quality between the old and new

qualities. In such cases it is necessary to estimate what would be the relative prices of the old and new models, or qualities, if they were produced and sold on the market at the same time and to use the estimated relative prices to determine measures of the relative qualities.

~~18.94~~18.94 When a model is missing a replacement of a comparable quality may be found and the price comparisons continued. If there is no comparable replacement, the price in the missing period may be imputed using the measured price changes of a product group expected to experience similar price changes. Dropping the product from the calculation is equivalent to an imputation that assumes the price change for the missing model would follow those of all goods and services in the index. The assumptions behind such imputations are less soundly based than those behind the more targeted imputation. In either case, items subject to quality change tend to be atypical and unrepresentative, so that assuming that their prices change at the same rate as for goods or services whose characteristics do not change is questionable.

~~18.92~~18.95 If the replacement model is not directly comparable in quality, then the price change of the new model may be readily linked to the price series of the old one if the two models are for sale in the market at the same time, in an overlap period. The implicit assumption is that the difference in prices at the time of the overlap link is a good valuation of the difference in quality, an assumption that will not be valid if the overlap period is at an unusual point in time in the model's life cycle, for example when it is about to become obsolete and discontinued or has just been introduced at an unusually high price to obtain temporary monopoly profits in a segmented market.

### Rapidly changing differentiated product markets

~~18.93~~18.96 Problems of adjusting price changes for changes in quality in product markets with a rapid turnover of differentiated varieties require special consideration. The matched model method breaks down. Models of like quality can only be compared over relatively short periods and are not representative of the overall market. The summation in index number formulae such as the Laspeyres price index in equation (1) is misleading since in period  $t$  the  $n$  items produced or consumed may be quite different from those on the market in period 0.

~~18.94~~18.97 Price index number compilers use a short-run formulation to ameliorate the difficulties of comparing the prices of like with like when there is a rapid turnover in differentiated goods and services. A Laspeyres price index, for example, comparing prices in period 0 and  $t$ , is given as:

$$L_P = \frac{\sum_{i=1}^n p_i^0 q_i^0 \left( \frac{p_i^{t-1}}{p_i^0} \right) \left( \frac{p_i^t}{p_i^{t-1}} \right)}{\sum_{i=1}^n p_i^0 q_i^0} \quad (17)$$

~~18.95~~18.98 If a new type of good, for example a digital camera, is introduced in period  $t-1$  to replace a non-digital one, then the compiler has only to wait for the good to be on the market for two successive periods before it can be included in the index. This provides a mechanism for changing the representative items to include the new, higher quality, item within a product category that has an assigned weight. Additional weighting information may be required to augment the weighting given to cameras within the wider group. However, a chain formulation in which weights are regularly updated would be a better mechanism to achieve this.

~~18.96~~18.99 While a chain index with a short-run formulation such as in equation (17) will ameliorate the measurement problem in markets with a rapid turnover of differentiated varieties, it cannot take account of the effect on the overall price change from period  $t-1$  to period  $t$  of the new variety introduced in period  $t$  and of the old model that was dropped in period  $t-1$ . Two successive price quotes are required to implement the formula in (17) and a chain index. Hedonic indices are a means of incorporating such affects. They can take a number of forms, but essentially the prices and values of price-determining quality characteristics, say the speed, RAM, etc. of different varieties of personal computers are collected in each period. A Paasche-type hedonic imputation (or characteristics) price index would be derived by first estimating a

hedonic regression of price on quality variables based on period  $t-1$  data and then using the estimated coefficients to impute for  $t-1$  the prices of the varieties available in period  $t$ , including those not available in  $t-1$ . Prices for period  $t$  characteristics valued at period  $t$  prices can be directly compared with the estimated period  $t-1$  valuation of period  $t$  characteristics to yield a Paasche-type price index. A Laspeyres-type hedonic index can be similarly defined using an estimated period  $t$  regression and constant period  $t-1$  characteristics set, as can a Fisher-type hedonic index as a geometric mean of the two. An alternative formulation is to pool the two sets of observations in periods  $0$  and  $t$  and include a dummy variable in the hedonic regression equation to distinguish observations in one period from those in the other. The coefficient on the dummy variable would be an estimate of the price change between the two periods having controlled for the effect of quality changes.

#### Further elaboration

~~18.97~~18.100 A detailed account of all the methods referred to above is available in chapters 6 and 7 of the CPI manual and chapters 7 and 8 of the PPI manual. These chapters include the use of imputations, overlap prices, comparable replacements, non-comparable replacements using estimates from production costs, option costs and hedonic regressions, as well as methods for markets with a rapid turnover of differentiated varieties including short-run relatives, chaining, product augmentation and hedonic indices.

~~18.98~~18.101 Further discussion of this topic can also be found in Handbook on Hedonic Indices and Quality Adjustments in Price Indexes: Special Application to Information Technology Products (Organisation for Economic Cooperation and Development, 2004).

### 6. Practical advantages of compiling chain indices

~~18.99~~18.102 It has been shown on theoretical grounds that long time series of volume and price indices are best derived by being chained. The question is how often in the time series should a link occur. It has been argued that annual chaining is generally best on theoretical grounds, but what of the practicalities? There are a number of matters to consider, including data requirements, computing requirements, human resource requirements, loss of additivity, revisions and informing users.

- a. If annual current values and corresponding volume or price data are available, then annual chaining is possible. No other data are required.
- b. The computing requirements of deriving annual chain indices are greater than those for fixed-weighted Laspeyres-type indices and should not be attempted without adequate, tailored software, ~~though improvements in the computational capacity of software used for compilation have made this objection less important. The complexity of the software needed depends on the formula used and the method of linking. For instance, it is quite simple to develop software to derive annually chained Laspeyres-type quarterly volume measures using the annual overlap method.~~
- c. Experience has shown that if the benefits of chain volume measures, along with the loss of additivity, are carefully explained to users via documentation and seminars before their introduction, chain volume measures are generally accepted. Particular attention should be given to informing the key users, including economic journalists, well beforehand.
- d. When volume estimates are rebased, say every five or ten years, ~~without chaining annually~~ then it is typically the case that the growth rates are revised. If price and volume relativities have been changing rapidly, then the changes in the growth rates can be dramatic. Such is usually the case for any aggregate in which computers have a significant share. With annual chaining history is only "rewritten" a little each year, not in one large jump every five or ten years. Not surprisingly, the sort of big revisions associated with chaining only every five or ten years can have a detrimental effect on user confidence in the national accounts, not least because users learn they can expect similar revisions in the future. Annual chaining not only measures changes better, it is likely to increase confidence in the resulting national accounts volume indices.

### C. Derivation of volume measures in the national accounts

## 1. Introduction

~~18.100~~18.103 This section is concerned with the application of the theory described in section B to the practice of deriving volume measures of parts of the SNA. The parts concerned are primarily the components of the goods and services account. Ideally this should be done within the context of supply and use tables, as explained below. Just as flows of capital formation can be expressed in volume terms, so can stocks of non-produced assets. It is not considered possible to separate all income flows into price and volume components but some limited measures of real income are possible, as also explained below.

~~18.101~~18.104 The ideal way of producing volume estimates of macroeconomic aggregates is to work at a very detailed level, deflating each component by a strictly appropriate price index. There are cases, though, where this approach is not possible; either appropriate price indices do not exist, or there may be inconsistencies in the current value data or the price indices, that make the results of deflation questionable. In such cases, alternative approaches must be considered including the possibility of projecting (or extrapolating) forward estimates for earlier years or using alternative indicators of the volume growth in a particular case.

~~18.102~~18.105 Once a set of volume measures is available for a given period, it needs to be presented with data for other periods in time series form. This is when chaining should be introduced for data derived by deflation of individual components. As recommended in section B, this should ideally be done annually using price indices of the previous year but if this is not possible, chaining over a longer period should be adopted. Major changes in economic structure, such as the impact of rapid fluctuations in oil prices on an oil exporting economy indicate that using the same base year before and after the change is likely to give quite misleading indications of the evolution of the economy. Chaining becomes essential rather than just desirable in such cases.

### Terminology for volume estimates

~~18.103~~18.106 When time series are constructed by dividing the current values for each year at the most detailed level possible by fixed base year Laspeyres price indices, it is appropriate to describe the resulting series as being at the constant prices of the base year. (This is because as long as the work is done at a sufficiently detailed level, the result approximates using a Paasche price index.) However, when each year's value is deflated by a price index with a different base year, it is no longer strictly correct to describe the resulting time series in this way. More accurate terms are "chain volume series", "chain volume measure" or "chain volume index" if the series is expressed in index number form. If it is desirable to specify the reference year in the term, then "chain volume series in reference year [currency units]" may be used.

~~18.104~~18.107 The use of the term "at constant prices" is also inappropriate for series that are linked less frequently than annually and to volume series based on the use of Fisher or Törnqvist formulae, whose price configurations are not constant over the duration of the series. For such series the terms "volume series" or "volume index" are appropriate to describe a series or index.

~~18.105~~18.108 The change of terminology also reflects the loss of additivity of the resulting time series since only series expressed in the same set of prices throughout, for example by using Laspeyres indices, are additive.

## 2. Price deflation vs. quantity revaluation

~~18.106~~18.109 Volume and price indices can only be derived for variables that have price and quantity elements. All transactions involving the exchange of goods and services and the levels of stocks of non-financial assets have this characteristic but income flows and financial assets and liabilities do not. Some balancing items have the characteristic but others do not and so they need to be considered individually.

~~18.107~~18.110 While both volume and price measures are of major importance in the national accounts, the principal focus of users is on the growth rates of volume measures, rather than prices. The compilation of the national accounts in volume and current value terms reflects this priority, with the price aggregates being derived implicitly, by dividing the current values by the corresponding volumes.

~~18.108~~18.111 When independent, reliable and comprehensive data are available at current values it is generally

not necessary to construct volume measures by aggregating quantity relatives. In most cases it is preferable and more practicable to use price indices to deflate current value data. Even for cases like electricity where the volume measure seems to be easily available, a direct volume measure is inappropriate because of the treatment of prices applying in different markets as explained in paragraphs 18.69 to 18.75. A change in the composition of the type of user leads to a change in the price and volume of electricity in the SNA even though the physical measure of electricity distributed may not have changed.

18.109 18.112 As explained in section B, price information is easier to collect and aggregate than volume information because all prices are expressed in a common unit whereas volumes come in a multitude of units. Further, price relatives for a representative sample of goods and services can be used as typical for all goods and services in the same group in a way that volume measures would not be representative. More importantly, the volume changes associated with new and disappearing products can be properly reflected when current values are deflated by price indices as described in section B.

18.110 18.113 For some products, for example closely specified agricultural products or minerals, it may be that the current value data have been constructed by multiplying a volume measure by an appropriate price. These are instances when there is no aggregation problem across the group of products and adjustments for quality differences are more easily and more satisfactorily made to the volume measures directly. While some such products may be of significant value in some countries, it will be a small number of the total number of products that can best be treated in this way.

18.111 18.114 To obtain a Laspeyres volume measure the appropriate price index used to deflate the current value is a Paasche index and vice versa. However, the available price indices are nearly always constructed using the Laspeyres or Lowe formulae, because construction of a Paasche price index has exactly the same data requirements as the direct derivation of a Laspeyres volume index and faces the same problems. If robust current value data and Laspeyres price indices are available at a sufficiently detailed level then Paasche volume indices, at the detailed level, can be aggregated using the Laspeyres formula to obtain an approximation of a true Laspeyres volume measure of the aggregate.

18.112 18.115 A Fisher volume index can be obtained either by taking the geometric mean of Laspeyres and Paasche volume indices or by deflating an index of the current values by a Fisher price index.

### 3. Available price indices

18.113 18.116 There are four major types of price index available to derive volume measures in the national accounts: consumer price indices (CPIs), producer price indices (PPIs), export price indices (XPIs) and import price indices (MPIs). CPIs are measures of purchasers' prices and PPIs are measures of basic prices. XPIs are measures of FOB prices; MPIs may measure FOB or CIF prices.

18.114 18.117 There are two defining aspects of recording transactions: timing and valuation. It is therefore critical that the price indices and the current values they are used to deflate correspond in both these aspects, as well as scope. The four types of price indices are usually available monthly and so quarterly and annual deflators can be obtained for flow and stock variables by averaging the monthly indices appropriately to centre the average at the desired valuation point. For flow variables this is usually the mid-point of the period, while for stock variables it is usually, but not always, the end of the period. For flow variables, the average price of the period should reflect known variations within the period. This is particularly important when there is a strong seasonal pattern, large irregular movements in certain months or hyperinflation. When none of these factors is present, the average price will be close to the observed price at the middle of the time period. The fact that this is frequently the case does not imply that the midperiod price is always the conceptually correct one to take, however.

### 4. The supply and use tables as the basis for volume measures of GDP

18.115 18.118 Chapter 14-15 describes the supply and use tables. It explains how the supply table itemizes the products each industry produces which are then identified in the use table where the allocation of each product between intermediate consumption and final demand is spelled out. Compiling supply and use tables at current values ensures consistency in the different measures of GDP. More powerfully, compiling supply

and use tables in volume terms ensures that both the volumes and prices in the SNA are consistent. In principle, tables at current values and in volume terms should be compiled at the same time in order to make the best use of all the information available to the compiler.

~~18.116~~18.119 It is often the case that not all the detailed data required for compiling supply and use tables are available each period and estimates have to be made to fill the empty cells. For example, detailed data for intermediate consumption by product by industry are often collected infrequently. It is generally better to make an initial assumption of a constant composition of intermediate inputs over time in volume terms than in current values. Furthermore, adjustments to the raw and estimated data can be greatly assisted by evaluating growth rates in prices and volumes from the previous or following period. For these reasons it is recommended that supply and use tables should be compiled at current values and in volume terms at the same time and balanced simultaneously.

~~18.117~~18.120 In order to derive a set of supply and use tables in volume terms that are additive, the appropriate way to proceed is first to express the table in the prices of the previous year, that is, as Laspeyres volume indices linking the previous year to the current year, referenced to the values in the previous year. In order to obtain annual chain Fisher volume measures, it is also necessary to derive supply and use tables of the previous year in the prices of the current year. Such values are in effect backward-looking Laspeyres indices referenced to the prices of the current year. Paasche volume indices are obtained by taking the inverse of the backward-looking Laspeyres indices. Fisher volume indices can then be derived as the geometric mean of the Laspeyres and Paasche volume indices between two adjacent years.

## 5. Volume measures of the output estimate of GDP

### Market output

~~18.118~~18.121 In principle, PPIs can be compiled for all market output and then they can be used to deflate current values to obtain volume estimates.

~~18.119~~18.122 In practice, there are some products for which it is very difficult to derive price indices and special steps must be taken to derive the corresponding volume measures. A particular case is those of margin industries including financial services. Output of a margin industry is usually calculated as the margin rate times the value of a transaction. To determine a volume figure the base year rate is applied to the value of the transaction suitably deflated to base year values. [As explained in section E.7 of this chapter](#), in the case of [implicit financial services on loans and deposits](#), the reference rate and the rates of bank interest are used in conjunction with figures of loans and deposits deflated by the general price increase since the base year.

~~18.120~~18.123 In other cases where there is no suitable deflator to apply to a current value, volume indices may be derived by extrapolating the current values in the base period by suitable indicators.

### Non-market output of government and NPISHs

~~18.121~~18.124 The current value of the output of non-market goods and services produced by government units or NPISHs is estimated on the basis of the sum of costs incurred in their production, as explained in chapter [67](#). This output consists of individual goods and services delivered to households and collective services provided to the community as a whole. The fact that such output is valued on the basis of the value of inputs needed to produce them does not mean that it cannot be distinguished from the inputs used to produce it. In particular, the change in the volume of output can be different from the change in the volume of inputs. Changes in productivity may occur in all fields of production, including the production of non-market services.

~~18.122~~18.125 In practice, there are three possible methods of compiling volume estimates of the output of non-market goods and services. The first is to derive a pseudo output price index such that when it is compared to the aggregate input price index the difference reflects the productivity growth thought to be occurring in the production process. Pseudo output price indices can be derived in various ways, such as by adjusting the input price index according to the observed productivity growth of a related production process or by basing the growth of the pseudo output price index on the observed output price indices of similar products.

However, such data are rarely available for the goods and services produced by government and NPISHs.

~~18.123~~18.126 The second approach, the “output volume method,” is recommended for individual services, in particular, health and education. It is based on the calculation of a volume indicator of output using adequately weighted measures of output of the various categories of non-market goods and services produced. These measures of output should fully reflect changes in both quantity and quality.

~~18.124~~18.127 The third approach, called the “input method”, may be used for collective services such as defence for which the “output volume method” is hardly applicable because there are, in general, no adequate quality-adjusted quantity measures of output. The “input method” consists of measuring changes in output by changes in the weighted sum of volume measures of all the inputs. The latter should fully reflect both changes in quantity and quality. They are generally best derived by deflating the various input costs by corresponding constant-quality price indices, or when such price indices are unavailable, using volume indicators that reflect input volume change (for example, number of hours worked by employees).

~~18.125~~18.128 It is useful at this stage to define the terms input, activity, output and outcome. Taking health services as an example, input is defined as the labour input of medical and non- medical staff, the drugs, the electricity and other inputs purchased and the depreciation of the equipment and buildings used. These resources are used in the activity of primary care and in hospital activities, such as a general practitioner making an examination, the carrying out of a heart operation and other activities designed to benefit the individual patient. The benefits to the patient constitute the output associated with these input activities. Finally there is the health outcome, which may depend on a number of factors apart from the output of health care, such as whether or not the person gives up smoking.

~~18.126~~18.129 The measurement of the volume of output of non-market individual services should avoid two pitfalls. The first of these is that it should not be restricted to reflect the inputs or the activity of the unit producing the services. Inputs are not an appropriate measure and while activities may be the only available indicator and hence have to be used, they too are an intermediate variable. What should be measured is the service rendered to the customer. The second risk is that if outcome is defined in terms of the welfare objectives of the non-market service (for example, changes in the quality of health for the measurement of the health service, or changes in the quality of education for the measurement of the education service) the change in the volume of the output of the non-market unit cannot be reflected by the change in the indicators of outcome. This is because indicators of outcome can be affected by other aspects that are not directly related to the activity of the non-market services. For example, in the case of health, it is well- known that there are many factors other than the output of the non-market health units, such as sanitation, housing, nutrition, education, consumption of tobacco, alcohol and drugs, pollution, whose collective impact on the health of the community may be far greater than that of the provision of health services. Similarly, the output of education services is quite different from the level of knowledge or skills possessed by members of the community. Education services consist principally of teaching provided by schools, colleges, universities to the pupils and students who consume such services. The level of knowledge or skills in the community depends in addition on other factors, such as the amount of study or effort made by consumers of education services and their attitudes and motivation.

~~18.127~~18.130 In the light of these observations, the “output volume method” is the recommended method for compiling indicators of volume change of non-market services. The method is based on quantity indicators, adequately quality- adjusted, weighted together using average cost weights. Two criteria should be respected to compile adequate indicators of volume change. In the first place, the quantities and costs used should reflect the full range of services for the functional area under review and cost weights should be updated regularly. If part of the costs of the functional area is not covered by the quantity indicator, it should not be assumed that the uncovered part follows the changes of the part that is covered. If no direct output volume method is applicable for this part, an input method should be used for it. Secondly, quantity indicators should be adjusted for quality change. For example, services should be sufficiently differentiated with the aim of arriving at categories that can be regarded as homogeneous. An aspect of quality change is then captured by changes in the proportions of different categories if the weights assigned to each category are frequently updated. In addition, the quantity indicator of each category can be augmented by an explicit quality adjustment factor. One way of identifying explicit quality adjustment factors is by reviewing the effects that the service has on measures of outcome. When feasible, direct volume measures should be preferred for individual non-market services as described in the Handbook on prices and volume measures in national

[accounts \(Eurostat, 2016\) or the handbook \*Towards measuring the volume of health and education and services\* \(Organisation for Economic Co-operation and Development, 2009\). Compilers should take account that quite some progress has been made to derive volume estimates of output, especially for education and health, that take account of changes in the quality as well as the quantity of the services provided.](#)

~~18.128~~[18.131](#) It is recommended these volume indicators be tested for a substantial period of time with the aid of experts in the domain prior to their incorporation in the national accounts. Expert advice is particularly relevant in the areas of health and education, which usually dominate the provision of individual services. Further, the consequences of the estimates including the implications for productivity measures should be fully assessed before adoption. Unless and until the results of such investigations are satisfactory, it might be advisable to use the second best method, the “input method”.

~~18.129~~[18.132](#) Measuring changes in the volume of collective services is generally more difficult than measuring the volume changes in individual services because the former are hard to define and to observe. One reason is that many collective services are preventative in nature, protecting households or other institutional units from acts of violence including acts of war, or protecting them from other hazards, such as road accidents, pollution, fire, theft or avoidable diseases are concepts that are difficult to translate into quantitative measures. This is an area in which further research is needed.

~~18.130~~[18.133](#) When it is not possible to avoid using an input measure as a proxy for an output measure, the input measure should be a comprehensive one, it should not be confined to labour inputs but cover all inputs. In addition, explanatory information should accompany the national estimates that draw users’ attention to the methods of measurement.

### **Output for own final use**

~~18.131~~[18.134](#) Output for own final use falls into two categories, goods produced and consumed by households and fixed assets produced for own use. Included in the above are changes in inventories of finished goods and work-in-progress.

~~18.132~~[18.135](#) For most output for own final use the use of pseudo output price indices is an effective, low-cost option. For goods produced and consumed by households, CPIs are likely to be available for similar goods. (However, for agricultural output grown and consumed by households, the price index used should not include any margins or taxes not actually incurred.) Similarly, there are likely to be output price indices available for fixed assets such as equipment, buildings and structures produced for own use as capital formation. For some types of fixed asset produced on own account there may be no output price indices available for similar products and different strategies may need to be considered. This is discussed further in the section on gross fixed capital formation.

### **Intermediate consumption**

~~18.133~~[18.136](#) As noted earlier, the most robust way of estimating intermediate consumption in volume terms is within the framework of a supply and use table in volume terms where information on volume growth rates as well as price information may be used.

~~18.134~~[18.137](#) Countries that compile PPIs generally do so for outputs, though countries with developed statistical systems may also compile input PPIs. Such input PPIs are directly applicable to the deflation of intermediate consumption.

~~18.135~~[18.138](#) If input PPIs are not compiled, output PPIs, MPIs and, to a limited extent, CPIs may be used instead. Intermediate consumption is valued at purchasers’ prices, while output PPIs are valued at basic prices. There is thus a margin between the valuation of goods used as intermediate consumption at purchasers’ prices and output PPIs, which is accounted for by transportation costs (unless the producer provides these services without a separate invoice), possible insurance costs, wholesale and retail trade margins and taxes less subsidies on products. The size of this margin will depend on circumstances. Often trade margins on goods for intermediate consumption are much smaller than for final consumption and the taxes may be smaller under a VAT system. For services used as intermediate consumption, the difference

in valuation usually consists of only taxes less subsidies on products.

~~18.136~~18.139 Chapter 44-15 describes how the intermediate consumption part of the use matrix can be partitioned to show the domestic inputs at basic prices, imports, margins and taxes separately. If this information is available, the quality of the resulting deflation exercise will be improved since it will not be necessary to use the assumption that import, tax and margin proportions apply uniformly across the elements of the rows of the use matrix.

### Gross domestic product and gross value added

~~18.137~~18.140 When gross domestic product (GDP) is derived by summing final domestic expenditures and exports and subtracting imports, or by subtracting intermediate consumption from output and adding taxes less subsidies on products, volume measures of GDP can be obtained provided that the volumes being aggregated are additive, (that is, are based on the Laspeyres formula).

~~18.138~~18.141 Central to the production measure of GDP is value added, the balancing item in the production account. The most common practice is to deflate the values of output and intermediate consumption independently, industry by industry, and then derive the difference as value added for each industry. (This is known as the double deflation method.) Different price indices are necessary for two reasons. The first is because the goods and services included in intermediate consumption for any industry are not the same as the output of that industry. The second reason is that intermediate inputs are always measured at purchasers' prices whereas output is measured at either basic prices or producers' prices.

**Commented [ED3]:** Paragraph drawn from para. 18.27 of 2008 SNA.

~~18.139~~18.142 The gross value added of an establishment, enterprise, industry or sector is measured by the amount by which the value of the outputs produced by that establishment, enterprise, industry or sector exceeds the value of the intermediate inputs consumed. This may be written as:

$$\sum PQ - \sum pq \quad (18a)$$

where the Q's refer to outputs, P's their basic prices, q's to intermediate inputs and p's their purchasers' prices. Value added in year t at prices of year t is given by:

$$\sum P^t Q^t - \sum p^t q^t \quad (18b)$$

while value added in year t at the prices of the base year, 0, is given by:

$$\sum P^0 Q^t - \sum p^0 q^t \quad (18c)$$

This measure of value added is generally described as being obtained by "double deflation" as it can be obtained by deflating the current value of output by an appropriate (Paasche-type) price index and by similarly deflating the current value of intermediate consumption.

~~18.140~~18.143 While the double deflation method is theoretically sound, the resulting estimates are subject to the errors of measurement in the volume estimates of both output and intermediate consumption. This may be especially true if output PPIs are applied to inputs, many of which are imported. Because value added is the relatively small difference between two much larger figures, it is extremely sensitive to error. It is therefore advisable to compare the growth rates of the price and volume measures of value added over recent years with the corresponding growth rates of output and intermediate inputs and, if possible, with volume estimates of inputs of labour and capital services to check for plausibility.

~~18.141~~18.144 Because of the possible problems in trying to estimate value added using the double deflation approach, it is also common to estimate the volume movements of value added directly using only one time series, that is a "single indicator" method instead of double deflation. One such single indicator method is to extrapolate value added in proportion to the volume changes in the corresponding levels of output.

~~18.142~~18.145 The choice to be made between the use of a single indicator method (which may yield biased

results) or a double deflation method (which may yield volatile results) must be based on judgement. The same choice need not be made for all industry groups. Further, the single indicator method may be used for quarterly figures until the year is complete and better double deflation estimates are available.

~~18.143~~18.146 In certain non-market service industries, it may be necessary to estimate movements in the volume of value added on the basis of the estimated volume changes of the inputs into the industries. The inputs may be total inputs, labour inputs on their own or intermediate inputs on their own. For example, it is not uncommon to find the movement of the implicit volume of value added estimated by means of changes in [remuneration of employees](#) at constant wage rates, or even simply by changes in numbers employed, in both market and non-market service industries. (There is extensive work being carried out to improve these working assumptions by trying to measure the outputs of government-provided health and education more objectively.)

~~18.144~~18.147 Compilers of data may be forced to adopt such expedients, even when there is no good reason to assume that labour productivity remains unchanged in the short- or long-term. Sometimes, volume changes for intermediate inputs may be used, for example, short-term movements in value added in real terms for the construction industry may be estimated from changes in the volume of building materials consumed such as cement, bricks, timber, etc. The use of indicators of this kind may be the only way in which to estimate short-term movements in output or value added, but they are not acceptable over long time periods.

~~18.145~~18.148 [There is also interest in trying to associate movements in value added, after price effects have been eliminated, with changes in labour and capital inputs. These measures of multifactor productivity are discussed in Section F.3 of this chapter.](#)

**Commented [ED4]:** This paragraph is an abbreviated version of para. 18.28 of 2008 SNA.

## 6. Volume measures of the expenditure estimate of GDP

~~18.146~~18.149 [The measure of GDP easiest to express in volume terms is that of expenditure. As long as appropriate price indices exist, the estimates of final consumption expenditure of households, general government and NPISH, capital formation, exports and imports can be deflated without much conceptual difficulty. It is desirable to work at as great a degree of detail as possible using the product detail available for each aggregate. Care must be taken, as explained in section B.5 of this chapter, to ensure that differences in quality are properly accounted for in the price deflators. This is especially important in the case of capital formation where many items such as computers are subject to rapid technological change and many items are customized, for example large construction projects or pieces of heavy machinery built to individual specifications.](#)

**Commented [ED5]:** This paragraph was moved from para. 18.25 of 2008 SNA.

~~18.147~~18.150 Each of the components of the expenditure estimate of GDP should be expressed in volume terms. The main approaches to deriving these estimates are described in turn below.

### Household final consumption expenditure

~~18.148~~18.151 Household consumption expenditure should be deflated at as detailed a degree as possible. In general this will involve making use of CPIs though care is needed to ensure that the coverage of the CPI being used matches the category of consumption expenditure being deflated. Even where detailed estimates of consumption expenditure are not compiled from household surveys and other primary sources, having an estimate of household consumption expenditure by type of product from a supply and use table for deflation will significantly improve the estimate of consumption expenditure in volume terms as compared with the single deflation of a total figure only.

~~18.149~~18.152 A major component where CPIs are unlikely to be available is the measure of the rental services of owner-occupied dwellings. Three alternative approaches are outlined in chapter 11 of the CPI manual, but only the use-based approach is recommended for measuring the consumption of housing services in the national accounts. This approach can take either a user-cost formulation that attempts to measure the changes in the cost to owner-occupiers of using the dwelling, or a rental-equivalence formulation based on how much owner-occupiers would have to pay to rent their dwellings. The latter method is more generally adopted for CPIs.

## Final consumption expenditure by government and NPISHs

~~18.150~~18.153 The final consumption expenditure of general government and NPISHs consists of their non-market output less any revenue from incidental sales plus the value of goods and services purchased from market producers for onwards transmission to individual households at prices that are not economically significant less any partial payments. (The derivation of this identity is discussed in chapter 910.)

~~18.151~~18.154 Each of these items should be expressed in volume terms separately. The problem of measuring non-market output in volume terms is discussed above. For goods and services transferred to households, the price indices used should be those paid for the goods less the proportion that households pay. If the proportion of the price paid by government (or NPISHs) alters from one year to another, this is seen as a volume change in expenditure on the part of both general government (or NPISHs) and households.

~~18.152~~18.155 Price indices for services are more difficult to compile than for goods and this is especially so for non-market services. Because the current values of non-market services are usually determined as the sum of costs, the obvious approach is to deflate each of these (including calculating remuneration of employees at constant remuneration rates). However, this does not allow for any change in the quality of services provided and in particular for the impact of any productivity changes that may have been achieved. When feasible, direct volume measures should be preferred for individual non-market services as described in Handbook on prices and volume measures in national accounts and Towards measuring the volume of health and education and services.

**Commented [ED6]:** Paragraph based on para. 18.26 of 2008 SNA.

## Gross fixed capital formation

~~18.153~~18.156 The availability of appropriate price indices for gross fixed capital formation varies considerably between different types of asset.

~~18.154~~18.157 There are often CPIs-house price indices for new dwellings and PPIs for new buildings and structures. The costs of ownership transfer should be deflated separately. The current value and volume estimates are usually derived from separate estimates of the constituent parts, legal fees, transport and installation costs etc.

~~18.155~~18.158 For standard products used as capital formation, PPIs are likely to be available but much capital formation is specific to the purchaser and appropriate indices may have to be developed using the best information available.

~~18.156~~18.159 Price indices for equipment vary considerably in their growth rates. For example, price indices for computer equipment have fallen rapidly year after year while price indices for transport equipment have tended to increase. It is important in such cases that the different types of equipment are deflated separately using the matching price indices (or, equivalently, an appropriately weighted Paasche price index is used to deflate the aggregate).

~~18.157~~18.160 Intellectual property products are generally not well covered by available price indices. There are several reasons for this. One is that many intellectual products are produced for own use and there may be no observed market prices. Another is that intellectual property products are very heterogeneous. However, these are not insurmountable difficulties and there are strategies for addressing them. As examples, the two major items in this category, software and databases and research and experimental development, are considered. Techniques for deriving volume measures of software and databases are described in section E of this chapter, with additional guidance on measuring the prices and volumes of software and data provided in section E of chapter 22. For research and experimental development (R&D), although it is often undertaken on own account, given its heterogeneous nature the choice for deflation lies between deriving pseudo output price indices and using input price indices.

~~Research and experimental development (R&D) is another activity that is often undertaken on own account. However, given the heterogeneous nature of R&D, the choice for deflation lies between deriving pseudo output price indices and using input price indices.~~

### Changes in inventories

~~18.158~~18.161 Although changes in inventories may be small relative to other components of GDP, the fact that their relative size might change quite significantly from one period to the next means that they can make a significant contribution to changes in ~~the size of~~ GDP particularly in the quarterly national accounts. For this reason, the calculation of changes in inventories in volume terms is particularly important. However, it is also a challenging task. As noted in paragraph ~~15.62~~, ~~18.62~~, because changes in inventories can take positive, negative or zero values, a chain index should not be derived directly. Chain volume estimates of changes in inventories should be derived by first deriving chain volume estimates of the opening and closing stocks of inventories and then differencing them.

~~18.159~~18.162 Volume estimation should be undertaken at a detailed level for different types of inventories, (work-in-progress, finished goods, materials and supplies, goods for resale). Deflation of stocks of inventories must be related to the composition of those inventories in terms of products rather than to the industry holding those inventories. PPIs, MPIs, CPIs and labour cost indices are all commonly used in deriving deflators, with adjustments to the appropriate valuation basis. It is important to understand how enterprises value their inventories as this can provide information on not only the type of products but also the average length of time over which goods are kept in inventories.

~~18.160~~18.163 When goods are sent abroad for processing without a change of ownership, it must be remembered that some inventories may be held outside the national territory but national prices should be applied to them to derive their corresponding volumes.

### Acquisition less disposal of valuables

~~18.161~~18.164 National statistical offices generally do not compile specific price indices for valuables. The major constituents should be deflated using the most suitable price indices available.

### Exports and imports

~~18.162~~18.165 Exports and imports consist of both goods and services. For both exports and imports, goods and services are expressed in volume terms using quite different deflators because of the very different sources available for goods and services. Improvements have been made to price indices for external trade in services that have led to improved data in this area.

~~18.163~~18.166 The valuation of imports and exports of goods is discussed in chapter ~~14~~15. In principle, they should be valued when change of ownership between a resident unit and a non-resident owner takes place and include or exclude transportation costs according to whether the supplier does not or does include transportation to the purchaser in the price charged. In practice, however, many countries are dependent for data on imports and exports of goods on customs declarations that value imports on a CIF basis but exports on a FOB basis. This assumes that change of ownership always takes place at the border of the exporting country. For balance of payments purposes, imports of goods should be converted to a FOB basis also but this is usually done at an aggregate level and may only be disaggregated in the supply and use context if at all.

~~18.164~~18.167 Given the existence of detailed XPI and MPI for goods, it should be a simple matter to deflate the current value estimates of exports and imports of goods at as detailed a level as practical in order to approximate the use of Laspeyres volume or Paasche price indices. In order to compile detailed volume estimates of imports of goods in the supply and use tables either the CIF estimates should be put onto a FOB basis or the MPIs need to be adjusted to a CIF basis. The usual working assumption is that CIF and FOB approximate purchasers' and basic prices respectively but as explained in chapter ~~14~~15, the adequacy of the approximation depends on circumstances surrounding transport margins.

~~18.165~~18.168 XPIs and MPIs are compiled by three general methods the nature of which is largely dependent on the source data used. The first and predominant method, at least in terms of the number of countries using it, is unit value indices compiled from detailed import and export merchandise trade data derived from administrative customs documents. As pointed out in section B, unit value indices are not price indices since

their changes may be due to price and (compositional) quantity changes. However, they are used by many countries as surrogates for price indices. The second method is to compile price indices using data from surveyed establishments on the prices of representative items exported and imported. The surveyed prices will be of items that are defined according to detailed specifications so that the change in price of the same item specification can be measured over time. The third method is a hybrid approach that involves compiling establishment survey-based price indices for some product groups and customs-based unit value indices for others.

~~18.166~~18.169 The case for unit value indices derived from merchandise trade figures is based on the relatively low cost of such data. Their use as deflators requires some caution as they have been shown to be subject to bias when compared with price indices. The bias in unit value indices is mainly due to changes in the mix of the heterogeneous items recorded in customs documents, but also to the often poor quality of recorded data on quantities. The former is particularly important in modern product markets given the increasing differentiation of products. Unit value indices may suffer further in recent times due to an increasing lack of comprehensiveness of the source data with increasing proportions of trade being in services and by e-commerce and hence not covered by merchandise trade data. Further, countries in customs and monetary unions are unlikely to have intra-union trade data as a by-product of customs documentation. Finally, some trade may not be covered by customs controls, such as electricity, gas and water, or be of “unique” goods, such as ships and large machinery, with profound measurement problems for unit values.

~~18.167~~18.170 As noted above, current data sources for price indices for international trade in services are less comprehensive than in other areas. If MPIS and XPIs are available for exports and imports of services they can be readily used to derive the required volume estimates. If they are not, volume estimates of exports of services can be mostly derived using an assortment of PPIs and CPIs. For example, volume estimates of freight transport services could be derived using PPIs according to the form of transport, while volume estimates of accommodation services could be derived using the appropriate CPIs. If MPIS are not available for imports of services then price indices of the countries exporting the services, adjusted for changes in the exchange rate, may have to be used.

~~18.168~~18.171 It must be remembered that if imports of goods are valued including transport services, then these transport services should be excluded from total imports of services.

## 7. Volumes and prices for stocks of fixed assets and ~~consumption of fixed capital~~depreciation

~~18.169~~18.172 Derivation of Deriving volume estimates of depreciationstocks requires estimates of capital stock excluding the effects of price changes. The levels of capital stock are typically derived by cumulating capital formation in successive periods and deducting the amount that has been exhausted. It clearly makes no sense to aggregate estimates of capital formation at the prices actually paid since the effect of rising prices (even prices rising only moderately) will be to overstate the amount of “new” capital relative to “old”.

~~18.170~~18.173 The preferred technique is to estimate all capital still in stock at the price of a single year and then revalue this to the price prevailing when the balance sheet is to be drawn up, typically the first and last day of the accounting period. This should be done at the most detailed level practicable. More on this can also be found in chapter 17.

~~18.171~~18.174 Consider first a single type of fixed asset. The stock of this type of asset consists of a number of items, typically of different vintages, that are valued and aggregated with a consistent set of prices. “Consistent” is to be understood here meaning the prices relate to the same period or point in time and being based on the same price concept, such as purchasers’ prices. Measuring stocks at historical prices, that is, by adding up quantities that have been valued with prices of different periods is therefore an inconsistent valuation. It is sometimes found in enterprise accounts but does not constitute an economically meaningful measure in the context of the SNA.

~~18.172~~18.175 The price vector used to value the quantities of fixed assets has to refer to a point in time (beginning or end of period) when the values of stocks are compiled for the opening or closing balance sheets. For other purposes, quantities of assets may be valued with a price vector that refers to the average of an accounting period. For example, measures of depreciation may be derived by subtracting the closing stock of assets

**Commented [ED7]:** These two paragraphs are based on paras. 18.31-18.32 of 2008 SNA.

from the opening stock plus gross capital formation as long as average-period prices are used for each component in order to eliminate holding gains and losses (and assuming no other volume changes in assets).

~~18.173~~18.176 The process by which many capital stock measures are constructed is the perpetual inventory method (PIM). For a given type of fixed asset, time series of gross fixed capital formation are deflated by means of the purchasers' price index of the same asset type, so that the quantities of assets are expressed in volume terms of a particular reference period. These time series in volume terms are then aggregated to yield a stock measure, where account is taken of retirement, efficiency losses or depreciation, depending on the nature of the stock measure constructed. The resulting stock measure is thus expressed in volume terms of the reference period chosen. This reference period may be the current period and stock measures valued in this way have often been labelled "current price capital stocks". However, this is not entirely accurate; as the description of the PIM showed, deflation is needed to arrive at these measures. Thus, they constitute a special case of a constant price valuation, namely valuation at the price vector of the current period.

~~18.174~~18.177 Even when the PIM is not applied, for example in the case of direct surveys of assets, the valuation of different vintages of a particular asset should not use book values that reflect historical prices. Consistent valuation requires that older vintages are valued by the prices of assets of specified ages at the point in time to which the survey refers.

~~18.175~~18.178 The next step is to aggregate the movements in capital stocks of individual asset types in volume terms. The use of linked or chain indices, as discussed earlier, is appropriate when building up a series that extends to the distant past since the current period price configuration will not remain representative.

~~18.176~~18.179 Further details on the PIM, on the different types of capital stocks and their measurement are provided in chapter 17 and in Measuring Capital.

## 8. Volume measures for stocks of non-produced natural resources and depletion

~~18.177~~18.180 For natural resources, estimates of the physical stocks of particular types of assets may be available, whereas observed market prices may not be available. As discussed in chapters 11 and 14, in this situation the net present value of future benefits may be used to estimate the values in monetary terms to be recorded in the SNA balance sheets. For a single, homogeneous natural resource, the volume estimates will be proportional to the physical stocks, but for aggregating different types of natural resources, index numbers are used to derive volume estimates.

~~18.178~~18.181 Depletion of non-produced natural resources reflects the decline in the quantity of a stock that is not offset by regeneration of the stock. In physical terms, depletion is the decrease in the quantity or value of the stock of a non-produced natural resource over an accounting period that is due to extraction of the natural resource by economic units occurring at a level greater than that of regeneration. In monetary terms, it corresponds with the decline in future income, due to extraction, that can be earned from a resource, the value of which is based on the physical flows of depletion using the price of the natural resource in situ. For measuring depletion in volume terms, the valuation of the physical flows of depletion uses the price of the natural resource in situ in effect in the reference period. If price indices need to be calculated, they can be derived as the ratio of the value expressed in current prices to the volume measure.

18.182 The change in volume of the stock during any period of any individual non-produced natural resource asset can be decomposed into the change in volume due to depletion, the change in volume due to capital formation (in the case of biological resources), and the change in volume due to other changes in assets (e.g., new additions to the stocks). The change in value of the stock in monetary terms is decomposed into depletion, other changes in assets, and revaluation. The depletion of non-produced natural resources in monetary terms is the change in physical stocks due to depletion multiplied by an average price in situ (i.e., the discounted unit resource rent) during the accounting period. The other changes in assets is the change in physical stocks due to other changes in assets times an average price in situ during the accounting period. The revaluation is the change in the price in situ multiplied by the average stock during the accounting period, though in practice it may be derived as a residual.

~~18.179~~18.183 For non-cultivated biological resources yielding once-only products, similar methodologies can be applied, albeit that the resource can also regenerate, thus giving rise to negative depletion. In the case of

**Commented [ED8]:** This is a new subsection largely drawn from Guidance Note WS.6

**Commented [ED9]:** The treatment of the change in volume of biological resources is under discussion. This paragraph will be edited to reflect the outcome of that decision.

cultivated natural resources yielding once-only products, the decrease in regenerative potential is recorded as depreciation, while an increase is recorded as fixed capital formation. For cultivated biological resources yielding repeat products, monetary values and volume estimates are typically compiled using the PIM methods as explained in the previous subsection, where the aggregation of volume estimates for individual asset types uses chain indices.

## 9. Components of value added

~~18.180~~18.184 The price and volume measures considered up to this point relate mainly to flows of goods and services produced as outputs from processes of production. However, it is possible to decompose some other flows directly into their own price and volume components.

### ~~Compensation of employees~~Remuneration of employees

~~18.181~~18.185 The quantity unit for remuneration of employees may be considered to be an hour's work of a given type and level of skill (see paragraphs 16.70 to 16.82 for more details). As with goods and services, different qualities of work must be recognized and quantity relatives calculated for each separate type of work. The price associated with each type of work is the compensation paid per hour which may vary considerably between different types of work. A volume measure of work done may be calculated as an average of the quantity relatives for different kinds of work weighted by the relative values of remuneration of employees in the previous year or a fixed base year. Alternatively, a "price" index may be calculated for work by calculating a weighted average of the proportionate changes in hourly rates of compensation for different types of work, again using relative remuneration of employees as weights. If a Laspeyres-type volume measure is calculated indirectly by deflating the remuneration of employees at current values by an index of hourly rates of compensation, the latter should be a Paasche-type index.

### Taxes and subsidies on products

~~18.182~~18.186 Taxes on products are of two kinds, specific taxes linked to the volume of the product and ad valorem taxes levied on the value of the product. A measure of the tax volume of the former can be derived by applying the base year rate of the specific taxes to suitably deflated current value figures of the items bearing the specific tax and for the latter by applying the base year ad valorem rates to current values of items subject to ad valorem taxes deflated by appropriate prices. It is possible to derive a ratio of the tax data in current values and in volume terms but it is difficult to interpret this as a price index since it reflects changing tax rates and changing composition of the purchases of items subject to tax. The calculation for subsidies is carried out in an analogous manner.

~~18.183~~18.187 There is more discussion on this in paragraphs 14.148 to 14.152.

### Net operating surplus and net mixed income

~~18.184~~18.188 When GDP is determined as the difference between output and intermediate consumption plus taxes less subsidies on production, gross value added is derived as an accounting residual. This is so in both current values and volume terms. In order for there to be an identity between different estimates of GDP in volume terms, it is not possible to give a price and volume dimension to gross value added. Rather the residual item is described as being "in real terms". If volume estimates of depreciation and depletion and remuneration of employees are available, net operating surplus and net mixed income can be derived but only in real terms and without a volume and price dimension. Thus it is not possible to derive an independent measure of GDP from the income approach since one item is always derived residually.

~~18.185~~18.189 The limit to a set of integrated price and volume measures within the accounting framework of the SNA is effectively reached with net operating surplus. It is conceptually impossible to factor all the flows in the income accounts of the SNA, including current transfers, into their own price and volume components. However, any income flow can be deflated by a price index for a numeraire set of goods and services to

measure the increase or decrease of the purchasing power of the income over the numeraire but this is quite different from decomposing a flow into its own price and volume components. A particular instance where this is common is in the calculation of the terms of trade effect on real income as described in section D.

## 10. Quarterly and annual estimates

~~18.186~~18.190 In principle, the same methods used to derive annual volume estimates should be used to derive quarterly volume estimates. Guidelines on data sources and methods for compiling price and volume quarterly estimates are given in chapters 3 and 8 of the Quarterly National Accounts Manual. The main considerations are those described in paragraphs ~~18.45 to 18.50~~. In practice, annual data are generally more comprehensive and accurate than quarterly data. Although there are important exceptions, such as exports and imports of goods, the overall situation is one of a much richer and more accurate, albeit less timely, set of annual data than quarterly data. For this reason, a sound approach is to compile balanced annual supply and use tables expressed in current values and in the prices of the previous year and to derive quarterly estimates that are consistent with them. This approach lends itself to the compilation of annually chained quarterly Laspeyres volume measures, although it can be adapted to the compilation of annually chained quarterly Fisher measures, too.

**Formatted:** Font: (Default) +Headings CS (Times New Roman), 10 pt, Complex Script Font: +Headings CS (Times New Roman), 10 pt, Don't snap to grid, Highlight

## 11. Supply and use tables in volume terms

~~18.187~~18.191 The rows of a use table show the way in which the total supply of a product is used for intermediate consumption, final consumption, capital formation and exports. This identity must hold in value terms. If the product in question is one where there is an unambiguous measure of quantity, the identity must also hold in volume terms. If the volume figures are derived by deflating the current values, the identity will only hold with certainty if each use category is deflated using a price index that is strictly appropriate to it.

**Commented [ED10]:** Subsection moved from 2008 SNA, 18.29–18.30.

~~18.188~~18.192 It is a good practice to compile supply and use tables in both current values and in volume terms at the same time so that the consistency of all the input data, including price indices, can be investigated together.

## 12. Summary recommendations

~~18.189~~18.193 The recommendations reached above on expressing national accounts in volume terms may be summarized as follows:

- a. Volume estimates of transactions in goods and services are best compiled in a supply and use framework, preferably in conjunction with, and at the same time as, the current value estimates. This implies working at as detailed a level of products as resources permit.
- b. In general, but not always, it is best to derive volume estimates by deflating the current value with an appropriate price index, rather than constructing the volume estimates directly. It is therefore very important to have a comprehensive suite of price indices available.
- c. The price indices used as deflators should match the values being deflated as closely as possible in terms of scope, valuation and timing.
- d. If it is not practical to derive estimates of value added in real terms from a supply and use framework and either the volume estimates of output and intermediate consumption are not robust or the latter are not available then satisfactory estimates can often be obtained using an indicator of output, at least in the short term. For quarterly data this is the preferred approach, albeit with the estimates benchmarked to annual data. An output indicator derived by deflation is generally preferred to one derived by quantity extrapolation.
- e. Estimates of output and value added in volume and real terms should only be derived using inputs as a last resort since they do not reflect any productivity change.
- f. The preferred measure of year-to-year movements of GDP volume is a Fisher volume index;

changes over longer periods being obtained by chaining, that is, by cumulating the year-to-year movements.

- g. The preferred measure of year-to-year inflation for GDP and other aggregates is, therefore, a Fisher price index; price changes over long periods being obtained by chaining the year-to-year price movements, or implicitly by dividing the Fisher chain volume index into an index of the current value series.
- h. Chain indices that use Laspeyres volume indices to measure year-to-year movements in the volume of GDP and the associated implicit Paasche price indices to measure year-to-year inflation provide acceptable alternatives to Fisher indices.
- i. Chain indices for aggregates cannot be additively consistent with their components whichever formula is used, but this need not prevent time series of values being compiled by extrapolating base year values by the appropriate chain indices.
- j. A sound approach to deriving quarterly current value and volume estimates is to benchmark them to annual estimates compiled in a supply and use framework. This approach lends itself to the construction of annually chained quarterly volume measures using either the Fisher or Laspeyres formulae.

## **D. Measures of real income for the total economy**

### **1. The concept of real income**

~~18.190~~18.194 Many flows in the SNA, such as cash transfers, do not have price and quantity dimensions of their own and cannot, therefore, be decomposed in the same way as flows related to goods and services. While such flows cannot be measured in volume terms they can nevertheless be measured “in real terms” by deflating their values with price indices in order to measure their real purchasing power over some selected basket of goods and services that serves as the numeraire.

~~18.191~~18.195 It is possible by use of a numeraire to deflate any income flow in the accounts and even a balancing item such as saving may be deflated by a price index in order to measure the purchasing power of the item in question over a designated numeraire set of goods and services. By comparing the deflated value of the income with the actual value of the income in the base year, it is possible to determine by how much the purchasing power of the income has increased or decreased. Income deflated in this way is generally described as “real income”.

~~18.192~~18.196 Despite the terminology used, “real” incomes are artificial constructs that are dependent on two points of reference.

- a. Real incomes are measured with reference to the price level in some selected reference year; they vary depending upon the choice of reference year.
- b. Real incomes measure changes in purchasing power over some selected numeraire; they vary according to the choice of numeraire

~~18.193~~18.197 As there may often be no obvious or uncontroversial choice of numeraire there has always been some reluctance to show real incomes in national accounts on the grounds that the choice of numeraire should be left to the user of the statistics and not the compiler. However, when major changes in prices occur, it can be argued that compilers of statistics are under an obligation to present at least some measures of real income. Not all users of the accounts have the opportunity, inclination or expertise to calculate the real incomes which may be most suited to their needs. Moreover, there is a demand from many users for multipurpose measures of real income, at least at the level of the economy as a whole and the purpose of this section is to indicate how such measures may be compiled.

### **2. Trading gains and losses from changes in the terms of trade**

~~18.194~~18.198 In a closed economy without exports or imports, GDP is equal to the sum of final consumption plus capital formation. This sum is described as domestic final expenditures. GDP is also a measure of the income generated in the economy by production. Although income cannot be expressed as the product of prices and volumes, if GDP can be deflated, then in effect this must also be a measure of income in real terms. However, with the inclusion of imports and exports, GDP is no longer identical to domestic final expenditure and deflation of GDP must allow for the deflation of imports and exports as well as of domestic final expenditures. Even if imports and exports are equal in current values, they usually have different prices so there is an impact on real income measures of import and export prices. This is generally done by considering the terms of trade and calculating what is known as the trading gains and losses from changes in the terms of trade.

~~18.195~~18.199 Further, the total real income that residents derive from domestic production depends also on the rate at which exports may be traded against imports from the rest of the world.

~~18.196~~18.200 *The terms of trade are defined as the ratio of the price of exports to the price of imports.* If the prices of a country's exports rise faster (or fall more slowly) than the prices of its imports (that is, if its terms of trade improve) fewer exports are needed to pay for a given volume of imports so that at a given level of domestic production goods and services can be reallocated from exports to consumption or capital formation. Thus, an improvement in the terms of trade makes it possible for an increased volume of goods and services to be purchased by residents out of the incomes generated by a given level of domestic production.

~~18.197~~18.201 *Real gross domestic income (real GDI) measures the purchasing power of the total incomes generated by domestic production.* It is a concept that exists in real terms only. When the terms of trade change there may be a significant divergence between the movements of GDP in volume terms and real GDI. The difference between the change in GDP in volume terms and real GDI is generally described as the "trading gain" (or loss) or, to turn this round, *the trading gain or loss from changes in the terms of trade is the difference between real GDI and GDP in volume terms.* The differences between movements in GDP in volume terms and real GDI are not always small. If imports and exports are large relative to GDP and if the commodity composition of the goods and services that make up imports and exports is very different, the scope for potential trading gains and losses may be large. This may happen, for example, when the exports of a country consist mainly of a small number of primary products, such as cocoa, sugar or oil, while its imports consist mainly of manufactured products. Trading gains or losses, T, are usually measured by the following expression:

$$T = \frac{X-M}{P} - \left\{ \frac{X}{P_x} - \frac{M}{P_m} \right\} \quad (19)$$

where

$X$  = exports at current values

$M$  = imports at current values

$P_x$  = the price index for exports

$P_m$  = the price index for imports

$P$  = a price index based on some selected numeraire.

$P_x$ ,  $P_m$  and  $P$  all equal 1 in the base year. The term in brackets measures the trade balance calculated at the export and import prices of the reference year whereas the first term measures the actual current trade balance deflated by the numeraire price index. It is perfectly possible for one to have a different sign from the other.

~~18.198~~18.202 In addition to changes in the terms of trade, another factor that may affect real income measures is changes in the relative price of traded goods and services (measured as the average of import prices and export prices) with respect to the price of nontraded goods and services. This factor is known as the real exchange rate effect. The effects of changes in the real exchange rate depend on the position of the trade

**Commented [ED11]:** This new paragraph acknowledges a point raised in an article in Review of Income and Wealth (2022) that real income measures are affected by real exchange rate effects as well as terms of trade effects.

account. For given terms of trade, if imports exceed exports, then a depreciation of the domestic currency (that is, an increase in the price of traded goods and services relative to nontraded goods and services) results in a decline in real income. On the other hand, if exports exceed imports, then these effects go in the opposite direction.

~~18.199~~18.203 There is one important choice to be made in the measurement of trading gains or losses, the selection of the price index  $P$  with which to deflate the current trade balance. There is a large but inconclusive literature on this topic, but one point on which there is general agreement is that the choice of  $P$  can sometimes make a substantial difference to the results. Thus, the measurement of real GDI can sometimes be sensitive to the choice of  $P$  and this has prevented a consensus being reached on this issue.

~~18.200~~18.204 It is not necessary to try to summarize here all the various arguments in favour of one deflator rather than another, but it is useful to indicate the main alternatives that have been advocated for  $P$ . They can be grouped into three classes, as follows.

- a. One possibility is to deflate the current balance,  $X-M$ , either by the import price index (which has been strongly advocated) or by the export price index, with some authorities arguing that the choice between  $P_m$  and  $P_x$  should depend on whether the current trade balance is negative or positive.
- b. The second possibility is to deflate the current balance by an average of  $P_m$  and  $P_x$  various different kinds of averages have been suggested, simple arithmetic or harmonic averages, or more complex trade weighted averages.
- c. The third possibility is to deflate the current balance by some general price index not derived from foreign trade; for example, the price index for gross domestic final expenditure, or the consumer price index. An advantage of a general price index not derived from foreign trade (such as the price index for gross domestic final expenditure) is that it incorporates real exchange rate gains and losses in addition to terms-of-trade gains and losses.

~~18.201~~18.205 The failure to agree on a single deflator reflects the fact that no one deflator is optimal in all circumstances. The choice of deflator may depend on factors such as whether the current balance of trade is in surplus or deficit, the size of imports and exports in relation to GDP, etc. On the other hand, there is general agreement that it is highly desirable and, for some countries vitally important, to calculate the trading gains and losses resulting from changes in the terms of trade. In order to resolve this deadlock it is recommended to proceed as follows:

- a. Trading gains or losses, as defined above, should be treated as an integral part of the SNA;
- b. The choice of appropriate deflator for the current trade balances should be left to the statistical authorities in a country, taking account of the particular circumstances of that country;
- c. If the statistical authorities within a country are uncertain what is the most appropriate general deflator  $P$  to be used, some average of the import and export price indices should be used, the simplest and most transparent average being an unweighted arithmetic average of the import and export price indices. (This is referred to in the specialist literature on the subject as the Geary method.)

~~18.202~~18.206 These proposals are intended to ensure that the failure to agree on a common deflator does not prevent aggregate real income measures from being calculated. Some measure of the trading gain should always be calculated even if the same type of deflator is not employed by all countries. When there is uncertainty about the choice of deflator, an average of the import and the export price indices is likely to be suitable.

### **3. The interrelationship between volume measures of GDP and real income aggregates**

~~18.203~~18.207 The usual way to calculate real income figures is to start from real GDI and then follow the normal sequence of income aggregates, but with every intervening adjustment deflated to real terms. This is

illustrated as follows:

- a. Gross domestic product in volume terms;  
*plus* the trading gain or loss resulting from changes in the terms of trade;
- b. *equals* real gross domestic income;  
*plus* real [earned incomes](#) receivable from abroad;  
*minus* real [earned incomes](#) payable abroad;
- c. *equals* real gross national income;  
*plus* real current transfers receivable from abroad;  
*minus* real current transfers payable abroad;
- d. *equals* real gross national disposable income;  
*minus* [depreciation and depletion](#) in volume terms;
- e. *equals* real net national disposable income.

~~18.204~~[18.208](#) The transition from (a) to (b) is the trading gain from changes in the terms of trade explained immediately above. The steps needed in order to move from (b) to (d) above involve the deflation of flows between resident and non- resident institutional units, namely, [earned incomes](#) and current transfers receivable from abroad and payable to abroad. There may be no automatic choice of price deflator, but it is recommended that the purchasing power of these flows should be expressed in terms of a broadly based numeraire, specifically the set of goods and services that make up gross domestic final expenditure. This price index should, of course, be defined consistently with the volume and price indices for GDP.

~~18.205~~[18.209](#) Each step in the process should first be calculated for adjacent years in additive volume terms and longer series derived as chain indices.

~~18.206~~[18.210](#) A possible alternative approach is to move from GDP in volume terms to net domestic final expenditure in volume terms and then make a single adjustment for the impact on purchasing power of the current external balance using the deflator for net final domestic expenditure to reduce the current external balance to real terms. The advantage of this alternative is a single numeraire, the set of goods and services making up net domestic final expenditures being used throughout. It may be easier, therefore, to grasp the significance of real net national disposable income as this deflator is explicit.

~~18.207~~[18.211](#) However, the alternative framework measures the trading gain or loss by using the deflator for net domestic final expenditures as the general deflator P, for the trading gain or loss from changes in the terms of trade whereas it can be argued that P ought always to be based on flows which enter into foreign trade. On balance, therefore, the original framework presented above is to be preferred.

## E. [Volume and price measures for particular products or industries](#)

~~18.208~~[18.212](#) For most products and industries, the methods discussed in Section C of this chapter can be used [to derive volume and price measures that are appropriate for national accounts. There are, however, several products that have somewhat unusual characteristics for which more specific guidance may be helpful. For a few particular products, this section provides a brief discussion of some of the challenges that arise for these products and explains some methods that some countries use to address these challenges. For further guidance on volume and price measurement for particular products or industries, please refer to handbooks on this topic, such as Eurostat, \*Handbook on Prices and Volume Measures in National Accounts\*, 2016 edition and the other references cited in this section.](#)

### 1. [Agricultural output](#)

**Commented [ED12]:** New section - Issue X.22 - Recommends adding new section on measuring prices, volumes for specific products.

**Commented [ED13]:** New subsection based on section 5.3.1 of Eurostat, *Handbook on Prices and Volume Measures in National Accounts*, 2016 edition.

~~18.209~~18.213 As discussed in paragraphs [7.148–7.150](#), the output of agriculture, forestry, and fishing is complicated by the fact that the process of production may extend over many months, or even years. For many crops the growing season will span three quarters of the year, with the harvest taking place in the third quarter, and preparation of the fields taking place in the last quarter of the preceding year.

~~18.210~~18.214 To derive volume measures of crop output, it is recommended that for each type of crop, the compilers distribute forecasts of the value of harvest output across the quarters in proportion to the input costs in each quarter. An alternative method is to assume that output in those quarters with no production of finished goods is equivalent to input costs. The alternative method avoids the necessity of deriving forecasts of the value of harvest output but could distort the quarterly pattern of output by assuming that the net operating surplus or net mixed income is entirely attributable to the quarter when the crop is harvested.

~~18.211~~18.215 When calculating the volume of quarterly agricultural output, the main difficulty is to decide which price index to use. Theoretically, the price to be applied should be the price prevailing during the period of production, but in practice the prices prevailing during quarters out of the harvest season might be rather unsuitable due to the scarcity of the crop outside of the harvest season. In such circumstances, it may be better to substitute prices related to the basic price forecast for final harvest output in place of the price prevailing in other quarters. If the alternative method discussed in the [previous paragraph](#) is used, it is important that one should continue to use a forecast of the product price as a deflator, since deflation by a price index for inputs would only generate the volume of inputs.

## 2. **Large construction projects**

~~18.212~~18.216 For construction, compilers are encouraged to avoid input cost methods and endeavor to develop output price indices that can be used for deflation. Compiling output price indices can be challenging, though, because each construction project tends to be unique in certain respects, so repricing identical models each period is challenging. For smaller projects, such as houses, small apartment buildings and small office buildings, it may be possible to collect information from construction enterprises on prices over time for a standardized “model” product, such as a typical family house with specified characteristics. For larger projects, such as large factories, highways, and reservoirs, the model pricing approach is not likely to be feasible and other methods must be considered.

~~18.213~~18.217 Specification pricing may be another possibility if it is possible to break down the attributes of the construction project into identifiable elements. This approach requires that the elements should be separately identifiable, their qualities and impact on the performance of the structure should be quantifiable, and prices for each element should be available in different periods. This approach has the advantage that it allows more flexibility than a standardized model, but in practice it may be difficult to identify the key elements of a project and to collect prices for each of those elements. A related method is the hedonic method, which also requires identifying characteristics that are thought to determine the price of the project, but uses regression methods rather than direct data collection to determine the price for each element.

~~18.214~~18.218 Although generally not the preferred method, the use of input prices may be acceptable when projects are so unique that it is not possible to use either specification pricing or the hedonic method to derive a price index.

## 3. **Digital goods and services**

~~18.215~~18.219 As discussed in chapter 22, digital products include assets that exist only in digital form and services that are supplied over a computer network. Examples of digital assets include crypto assets, data and software. Examples of digital services include wholesale and retail e-commerce distribution services, priced and free services of online platforms, audio and video streaming, and digital financial and payment services such as mobile money services. Their production and consumption are enabled by ICT equipment, software, and data and databases along with ICT consumer durable goods, and mobile and fixed line digital communication services. As an example, this section considers the volume and price measurement of software and databases.

~~18.216~~18.220 Volume and price measurement challenges are common for products affected by digitalization

**Commented [ED14]:** New subsection based on sections 2.5 and 4.6 of Eurostat, *Handbook on Prices and Volume Measures in National Accounts*, 2016 edition.

**Commented [ED15]:** New section per DZ.1, DZ.3, DZ.8. These topics are covered in detail in chapter 22.

because innovation leads to rapid changes in the characteristics and sources of supply of digital products. New digital products regularly disrupt existing ones, new models or service contracts frequently embody quality improvements, digital intellectual property products and services with no physical units of measurement are growing in importance, and free products often appear or cease to be free.

~~18.217~~18.221 To deal with these rapid changes, the samples used to calculate the price indexes for digital products subject to frequent quality improvements need to be regularly refreshed to keep them representative of current consumption patterns. In addition, the appearance of new models and the exit of obsolete models must be handled in a way that reflects the value of the quality changes. In some cases, the prices of new characteristics may be observable from the price differences associated with various options that the seller offers to consumers. Another way of handling these quality changes is through explicit estimation of quality changes through hedonic methods.

~~18.218~~18.222 These general issues and specific examples of volume and price measurement of digital products, including cloud computing and free products, are discussed in detail in section E of chapter 22. The example of software and databases is considered here.

~~18.219~~18.223 When deriving volume estimates of the capital formation of software and databases it is advisable to decompose software into three components: packaged (or off-the- shelf), custom-made and own account and to deflate them and databases separately. There are several reasons for doing this.

- a. The three components of software and databases vary in the extent to which price data are available to compile price indices.
- b. It is likely that their prices and volumes grow at different rates, particularly between packaged software, the other two software components and databases.
- c. Despite the previous point, price indices for packaged software may be used to construct price indices for the other two software components if more appropriate price indices are unavailable.
- d. Volume estimates of the items are useful indicators in their own right.

~~18.220~~18.224 Packaged software is purchased on a very large scale, generally via licences-to-use and there is an abundance of price data available. The challenge is to construct price indices free of the effects of changing specifications and any other aspects of quality change.

~~18.221~~18.225 Custom-made software is also sold on the market, but each custom-made software product is a one-off, which presents an obvious problem for compiling price indices. Although each custom-made product is different, different products may share common components, or a strategy used to develop one product may be able to be used for another. This not only suggests a possible way of compiling a price index, but also suggests means by which productivity gains could be made that would put downward pressure on prices. In sections B and E the use of model pricing is outlined for measuring price changes of custom-made buildings. A similar approach may be applied to custom-made software, or hedonic methods might be applied.

~~18.222~~18.226 Methods for compiling price indices for heterogeneous groups of products and products whose specifications are changing rapidly are described in the *Handbook on Hedonic Indices and Quality Adjustments* and in *Producer Price Index Manual: Theory and Practice*, (the International Labour Organization, International Monetary Fund, Organisation for Economic Co-operation and Development, United Nations, Economic Commission for Europe and the World Bank, 2004).

~~18.223~~18.227 A substantial proportion of software in gross fixed capital formation is undertaken on own account. Hence, it is not possible to derive a true output price index for such software. It is then a matter of choosing between a pseudo output price index and an input price index, obtained by weighting together price indices of the inputs. As already noted, input volume estimates used as a proxy for output do not reflect any productivity growth and so this is not recommended. In the absence of a better alternative, the most obvious option is to use the price index for custom- made software.

~~18.224~~18.228 Databases are generally heterogeneous products with a small market since most databases are made for in-house purposes. Volume and price measures for data are discussed in section E of chapter 22. For

**Formatted:** Font: (Default) +Headings CS (Times New Roman), 10 pt, Font color: Auto, Complex Script Font: +Headings CS (Times New Roman), 10 pt, Don't snap to grid, Not Highlight

own-account software, it is difficult, if not impossible, to develop a true output price index and once again the choice is between a pseudo output price index and an input price index though a pseudo output index may be difficult to envisage.

#### 4. **Passenger transport services and price discrimination**

~~18.225~~18.229 It is not unusual for two airline passengers sitting in adjacent seats to pay very different prices for the same transport services. In some cases, there may be differences in the bundle of services provided with the ticket (for example, one ticket may provide for a refund if the ticket needs to be cancelled), but in other cases there are no meaningful differences in products characteristics. Rather, the difference in price may be explained by price discrimination.

~~18.226~~18.230 As explained in paragraph 18.71, price discrimination occurs when groups of purchasers who differ in their willingness to pay for a product are charged different prices by a seller who is able to segment the market and charge different prices based on those differences in willingness to pay. Price discrimination occurs more often in the provision of services than goods because goods can be retraded (and are thus subject to arbitrage), whereas services generally are not retraded. Other examples of services for which price discrimination may be common include electricity distribution, financial services, education and health.

~~18.227~~18.231 With respect to price and volume measurement, there are two key issues. The first is whether the prices truly are homogenous, or whether there are subtle differences in quality between items that appear to be identical (except for a difference in price). For example, an airline can charge more for economy class seats that offer more leg room than other economy class seats, and that difference should be treated as a difference in quality rather than price. It could also charge a different price for a seat purchased immediately before a flight than one purchased several weeks in advance. The compiler of the price index should try to hold such subtle differences in characteristics constant when specifying the description of the ticket that is being priced. But when price discrimination leads to different prices being charged for two products with no differences in quality, the differences should be attributed to price rather than volume.

~~18.228~~18.232 One way to ensure that differences in price due to price discrimination are not mixed in with volume would be to divide the customers into homogeneous groups. For example, on an air flight travelling on a specific route, the passengers may be grouped into first class, premium economy, and economy class. For each group, the volume is measured by the number of passengers taking the trip and the price is the average price paid by passengers within each group. This decomposition could then be applied to a representative sample of flights travelling on various routes to obtain price and volume indices for air transport services.

#### 5. **Output of the central bank**

~~18.229~~18.233 As explained in chapter 7, central banks provide a variety of financial services, including monetary policy services, services related to promoting financial stability, services related to managing international reserves and payment systems and services related to acting as banker to government. In general, these services are provided for free, or at prices which are not economically significant, for the benefit of society as a whole. These services of central banks are considered non-market output provided to the society as a whole (i.e., collective services), and total output is to be valued at the sum of costs. Unless an indicator of productivity is available (which is unlikely because the services of central banks generally cannot be observed), the most appropriate volume measure is the deflation of the inputs.

#### 6. **Implicit financial services on loans and deposits**

~~18.230~~18.234 As described in 7.179–7.188, implicit financial services on loans and deposits are implicit charges paid by depositors or borrowers to a financial institution such as a bank for the services associated with intermediation. These charges are indirect because they are derived from the interest rates associated with the loans and deposits in relation to a reference rate of interest and are not explicit fees charged for services. Thus, traditional methods of deflation are not available for these services and alternative methods must be

**Commented [ED16]:** Discussion of price discrimination is based on section 2.1.4 of Eurostat, *Handbook on prices and volume measures in national accounts* (2016 edition).

**Commented [ED17]:** New subsection reflecting issue note X.3 and Issues note on action point A.9 (AEG meeting July 10–13, 2023).

**Commented [ED18]:** New subsection based on issue note X.10; also draws on Eurostat, *Handbook on prices and volume measures in national accounts* (2016 edition).

used.

~~18.231~~18.235 Two main approaches have been used for volume and price measures of implicit financial services on loans and deposits. The *deflated stocks approach* involves deflating the stocks of loans and deposits using a general price index and applying the previous year's (or base year) reference rates to arrive at borrower implicit financial services and depositor implicit financial services in volume terms. The *output indicators approach* focuses on indicators of specific services that ~~that~~ the financial institution provides to borrowers and depositors, such as debit and credit card transactions, automatic teller machine transactions, and cheque transactions, which serve as proxies for the volume of financial services provided by the financial institution.

~~18.232~~18.236 The output indicators approach ~~is attempting~~attempts to decompose the services provided by a financial institution such as a bank into the distinct activities that it undertakes on behalf of its customers. Advantages of this approach are that the indicators may directly reflect the provision of services that customers value and provide insight into the activities undertaken by the bank. In practice, this approach has also encountered several obstacles and disadvantages. Indicators may not be available for all the specific services provided by banks, and the omission of services that are poorly measured could bias the rate of growth of the overall volume measure. The approach requires that the various output indicators should be weighted, and because there is no observable price or revenue for these services, deriving appropriate weights can be a difficult and complex task. The data burden of compiling the output indicators and their associated weights is likely to be high, and the indicators and weights may tend to become outdated in the face of technological changes and increased digitalization of financial services. In general, it may also be difficult to maintain such a measure and keep the weighting and list of indicators current in the face of rapid changes in the ways that financial services are provided and paid for.

~~18.233~~18.237 The more commonly used method is the deflated stocks approach, in which the stocks of deposits and loans are deflated using a general price index. Rather than decomposing the specific activities undertaken by banks, the deflated stocks approach takes the broader view that intermediation services are ultimately related to allowing the borrower or depositor to engage in deposit and loan transactions, either in the current period or in a future period. The stock of loans or deposits is related to the capacity to engage in transactions, and those transactions are best measured in volume terms using a general price index. In applying the deflated stocks approach, compilers should apply a general price index appropriate for the country and apply the previous year's reference rates to arrive at borrower implicit financial services and depositor implicit financial services in volume terms. Furthermore, because different kinds of loans or deposits have different margins between their interest rate and the reference rate, each type of loan or deposit should be deflated separately, and then the various types of loans and deposits should be aggregated using a price index formula (such as the Paasche price index or Fisher price index that have been discussed in this chapter). The general price index used for deflation should, if possible, exclude implicit financial services on both conceptual grounds (the transactions supported by loans and deposits do not include implicit financial services) and practical grounds (the inclusion of these services would create a circularity in the calculation of the overall index, which could be problematic). Stocks associated with exports of implicit financial services should be deflated using a general domestic price index, while for imports the appropriate country price indices should be used (along with exchange rate adjustments if the stocks are held in a different currency of that of the domestic economy).

~~18.234~~18.238 In view of its relative simplicity, the deflated stocks approach is generally preferred for calculating volume measures of implicit financial services on loans and deposits. Countries should select a general price index for deflation that is accurate and appropriate for the types of transactions that are most often supported by loans and deposits in the country. The output indicator approach could also be used to calculate volume measures of implicit financial services.

## 7. **Services of owner-occupied dwellings**

~~18.235~~18.239 As discussed in 7.126–7.128, households that own the dwelling they occupy are treated as owners of unincorporated enterprises that produce housing services consumed by those same households. When well-organized markets for rental housing exist, the output of own-account housing services can be valued using the prices of the same kinds of services sold on the market in line with the general valuation rules

**Commented [ED19]:** New subsection based on section 4.12.2 of Eurostat, *Handbook on Prices and Volume Measures in National Accounts*, 2016 edition and paragraphs 11.87 to 11.102 of *Consumer Price Index Manual*, 2020 edition

adopted for goods or services produced on own account. In other words, the output of the housing service produced by owner occupiers is valued at the estimated rental that a tenant would pay for the same accommodation, taking into account factors such as location, neighbourhood amenities, etc., as well as the size and quality of the dwelling itself. Due to the absence of an explicit price for these services, indirect approaches must be used to derive volume and price measures.

~~18.236~~18.240 The stratification approach is generally recommended by Eurostat's *Handbook on Prices and Volume Measures in National Accounts*, 2016 edition. In a benchmark year (or annually if the necessary data and resources are available), compilers match actual rents paid by those renting in particular strata to similar dwellings used by owner occupants in equivalent strata to derive their rental equivalence value. The benchmark estimate makes use of detailed data on the housing stock broken down between owner-occupied and rented property and by the attributes of these properties that influence the rent, such as floor area, number of rooms, number of bathrooms, etc. This method is known as the 'stratification method' because it is based on the stratification of dwelling attributes and rent. The approach can be seen as providing price and quantity data at a detailed level for the estimation of output for a particular year.

~~18.237~~18.241 Estimates for years other than the benchmark year are estimated by projecting forward the housing stock and rents with indicators that reflect the development of these variables over time. The indicators are chosen to reflect adequately the three components of change: the change in price, change in the quantity of the stock, and change in the quality of the stock.

~~18.238~~18.242 If the stratification method cannot be used, then price indices or volume indicators need to be constructed. The *Consumer Price Index Manual*, 2020 edition, paragraphs 11.87 to 11.102, discusses ways to estimate a price index for the services of owner-occupied dwellings that are broadly consistent with the concepts used in the SNA. The index can be calculated, for example, from a sample of rented housing units that are weighted to reflect the current composition of owner-occupied units. This approach requires that a country have a transparent rental market and reliable information on rents by type of accommodation, location and other rent-determining factors. In general, if the volume of the services of owner-occupied dwellings is to be calculated by deflation, care should be taken to ensure that the concepts and coverage in the deflator match the concepts and coverage used to measure the value of those services in the accounts.

~~18.239~~18.243 Whether the stratification method or the price index method is used, subsidized and controlled prices should not be used in calculating the owners' equivalent rental series, though they should be used in calculating the prices of rented units.

~~18.240~~18.244 Another consideration in deriving price and volume measures of the services of owner-occupied dwellings is the growing importance of owners subletting part or all of a dwelling to tourists or travelers. In particular, new digital marketplaces for subletting have made it easier to sublet a dwelling and have led to substantial growth in this activity. Traditional housing surveys may have considered this type of subletting to be too unimportant to measure, which may lead to omission or undercounting of these transactions. For the volume measure of the services of owner-occupied dwellings, if the value of the services is based on the rental equivalence of similar rented dwelling that is not sublet, the value of the subletting needs to be deducted from the rental equivalence of the owner-occupant's unit to avoid double counting the services of the unit (as explained in paragraphs 7.127 to 7.128).

## 8. **Education services**

~~18.241~~18.245 In section C.5 of this chapter, the general principles for measuring volumes and prices of non-market output are explained. Here an example is provided of how the volume of output of non-market education services might be estimated in practice. The handbooks, Eurostat, *Handbook on Prices and Volume Measures in National Accounts*, 2016 edition and OECD, *Towards Measuring the Volume Output of Education and Health Services: A Handbook*, 2009, provide more detailed guidance on these services.

~~18.242~~18.246 For primary and secondary education, educational output can be measured based on the amount of teaching received by the students for each type of education. This can be measured as the number of student-hours, or if this measure is not available, the simple number of students or pupils can be used provided the hours of instruction remain broadly stable over time. For higher education, and especially for specialized schools, such as medical schools, there may be other aspects of training that are more resource intensive

**Commented [ED20]:** New subsection based on Eurostat, Handbook on Prices and Volume Measures, and OECD, Towards Measuring the Volume Output of Education and Health Services.

and would not be captured by the hours of instruction. For those types of education, additional stratification and other indicators may need to be added.

## 9. **Health services**

~~18.243~~18.247 As for education services, we refer to section C.5 of this chapter for an explanation of the general principles for measuring volumes and prices of non-market output. Here an example is provided of how the volume of output of non-market health services might be estimated in practice. The handbooks, Eurostat, *Handbook on Prices and Volume Measures in National Accounts*, 2016 edition and OECD, *Towards Measuring the Volume Output of Education and Health Services: A Handbook*, 2009, provide more detailed guidance on these services.

~~18.244~~18.248 Health services are characterized by substantial heterogeneity in the conditions that are being treated and in the types of treatment that are appropriate for each condition. Because the treatment of a condition may involve a bundle of services provided over a period of time, including medical services, laboratory services, and in some cases hospital services, it may not be possible in practice to capture the full treatment of the condition. For hospital services, data may be classified based on the international classification of diseases (ICD) or on diagnosis related groups (DRG), which are systems used to classify medical conditions into relatively homogeneous categories.

~~18.245~~18.249 For market output of hospital services, a PPI or CPI that is representative and controls for quality may provide a good deflator. For non-market output of hospital services, volume estimates may be calculated on the basis of direct output measures such as number of discharges by ICD or DRG category weighted by appropriate cost or revenue weights. These methods should be applied at a detailed level to avoid mixing different types of treatments. The most used alternatives are either a unit cost index or a direct volume index, depending on data availability.

## F. **Estimating labour and multifactor productivity**

### 1. **Labour productivity**

~~18.246~~18.250 Volumes of output per hour worked (or per person employed) are described as measures of labour productivity. However, this is a somewhat unsophisticated measure because changes in this measure can reflect a number of factors other than just the number of hours of labour employed. In particular, increases in the amount of capital used can affect this ratio as can changes in the composition of the labour input over time. Volume measures of labour input are discussed in detail in section D of chapter 16, and the topics of labour, capital and multifactor productivity are discussed in detail in *Measuring Productivity*.

~~18.247~~18.251 Labour productivity shows the time profile of how productively labour is used to generate output in volume terms. Changes in labour productivity reflect the joint influence of changes in capital, intermediate inputs, as well as technical, organizational and efficiency change within and between enterprises, the influence of economies of scale, varying degrees of capacity utilization and measurement errors.

~~18.248~~18.252 Neither the number of employed persons nor full-time equivalent numbers on labour input are ideal measures for use in productivity studies. The series for total hours actually worked is preferred by many because it is a reasonable compromise between these cruder measures and data-intensive measures that adjust for differences in the qualifications, skill levels and composition of labour.

~~18.249~~18.253 Using total hours actually worked as the input measure for calculating labour productivity changes over time implicitly assumes that each hour worked is of the same quality. As discussed in paragraphs 16.95 to 16.97, it is possible to produce a quality-adjusted measure of the labour inputs that takes account of changes in the mix of workers over time by weighting together indicators of quality for workers with different levels of skill or education.

~~18.250~~18.254 Whichever labour measure is used in calculating productivity, it is very important to ensure that the coverage of the labour data is consistent with that of the national accounts. In other words, the labour inputs must be estimated within the same production boundary and using the same criteria for residence that are used in the national accounts. Typically, the topics that cause most difficulty are residence (particularly

**Commented [ED21]:** New subsection based on Eurostat, Handbook on Prices and Volume Measures, and OECD, Towards Measuring the Volume Output of Education and Health Services.

**Commented [ED22]:** New section that mostly draws from chapter 19, section E of the 2008 SNA, along with some material from pp. 14-18 of OECD, *Measuring Productivity*.

**Formatted:** Font: (Default) +Headings CS (Times New Roman), 10 pt, Font color: Auto, Complex Script Font: +Headings CS (Times New Roman), 10 pt, Don't snap to grid, Not Highlight

with border workers), defence force and diplomatic personnel (who are commonly not covered by the labour force surveys used to provide the basic data) and obtaining details of unpaid hours (for example, unpaid overtime) or of some self employment (for example, contributing family workers).

~~18.251~~18.255 Analysts are often interested in measuring productivity on an industry basis as well as for the economy as a whole. Calculating industry employment and working time by industry adds an additional degree of difficulty to the estimation process. Among other advantages, using hours worked overcomes the problems involved in measuring employment by industry when a worker has two or more jobs, not in the same industry.

~~18.252~~18.256 Labour productivity, including industry productivity, and multifactor productivity (see below) are all valid measures of an economy's performance. From a practical viewpoint, it is important to ensure that the employment and hours worked underlying these sets of estimates are consistent with each other as well as with output measures when calculating the productivity estimates.

### Data consistency

~~18.253~~18.257 Examining the relative productivity performance of different industries is of interest to many analysts. In practice, the labour input estimates for the whole economy can be estimated either "bottom up" or "top down". In the former case, the totals for the economy as a whole will be completely consistent with the industry estimates because they are summed to derive the total labour estimates. However, in the case of a top-down approach, a range of different data sources may be used to obtain the disaggregation by industry. In such cases, it is important to ensure that the sum of the industry estimates is consistent with the national totals.

~~18.254~~18.258 Classifying labour input by industry is not always straightforward. The main issue is to ensure that the employment estimates for each industry are as consistent as possible with the national accounts values and volumes so that the productivity estimates are reliable. One particular problem that arises is where staff are recruited via an external recruitment agency. Maintaining consistency with the industry output means that employment should be classified to the industry of the establishment that legally employs the workers. In practice, this will be the establishment that pays the employee's wages and any associated social contributions, which will usually be the employment agency and so the employees will be classified to industry class 7491 *Labour recruitment and provision of personnel*. The output of this industry includes the revenue derived from the activity of hiring out staff to those establishments that need the staff; generally, those establishments will be in other industries. The establishments using these staff pay the employment agency and then the employment agency pays the staff so the payments by the "using" establishments will be recorded as part of intermediate input for the using industry.

~~18.255~~18.259 Ideally, for productivity purposes both the output attributable to these staff and the hours they work would be recorded in the industry in which they are actually working rather than in the industry "Labour recruitment and provision of personnel". However, in practice, it is unlikely that the data can be collected to enable the output and hours worked to be classified this way. It may be useful for some purposes for the staff hired out by employment agencies to be allocated to the industries that actually use the staff. If such an allocation of labour input is performed, similar adjustments to intermediate consumption and value added of the relevant industries would also be required. However, any such allocation should be presented in a supplementary table and not in the main accounts.

## 2. Capital productivity

~~18.256~~18.260 Measures of capital productivity, calculated by dividing the volume of output (or volume of value added) by a volume index of capital services provided, suffer from similar drawbacks to labour productivity since they do not capture the effects of the amount of labour employed and the efficiency and composition of the capital inputs.

~~18.257~~18.261 The capital productivity index shows the time profile of how productively capital is used to generate value added or output. Capital productivity reflects the joint influence of labour, intermediate inputs, technical change, efficiency change, economies of scale, capacity utilization and measurement

**Formatted:** Font: (Default) +Headings CS (Times New Roman), 10 pt, Font color: Auto, Complex Script Font: +Headings CS (Times New Roman), 10 pt, Don't snap to grid, Not Highlight

errors. Like labour productivity, capital productivity measures can be based on output volume or value-added volume.

~~18.258~~18.262 The index of capital services is related to the capital services for the total economy, as shown in chapter 17, table [17.11](#). Volumes of capital services for the individual asset types and industries need to be aggregated using a Laspeyres or Fisher index to form an index of capital services for the total economy.

### 3. Multifactor productivity

~~18.259~~18.263 A measure that takes account of the contributions of both labour and capital to growth in output is multifactor productivity (MFP), which is sometimes referred to as total factor productivity (TFP). The advantage of using MFP as the measure of productivity is that it includes effects not included in the labour and capital inputs. This topic is discussed further in chapter 20 and in *Measuring Capital*.

~~18.260~~18.264 Capital-labour MFP is calculated as a volume index of value added divided by a volume index of combined labour and capital input. Capital-labour MFP indices show the time profile of how productively combined labour and capital inputs are used to generate value added. Conceptually, capital-labour productivity is not, in general, an accurate measure of technical change. It is, however, an indicator of an industry's capacity to contribute to economy-wide growth of income per unit of input. In practice, the measure reflects the combined effects of disembodied technical change, economies of scale, efficiency change, variations in capacity utilization and measurement errors.

~~18.261~~18.265 The productivity model can be extended to include other factors such as the energy and materials used in production. The abbreviation "KLEMS", standing for capital (K), labour (L), energy (E), materials (M) and purchased services (S), is often used for this extended productivity model. This can be extended to producing productivity estimates at the most detailed level of the supply and use tables. KLEMS MFP is calculated as a volume index of output divided by a volume index of combined inputs, including different types of labour, capital, energy, materials and services, each weighted with its share in total output. KLEMS MFP shows the time profile of how productively combined inputs are used to generate output. Conceptually, the KLEMS productivity measure captures disembodied technical change. In practice, it also reflects efficiency change, economies of scale, variations in capacity utilization and measurement errors.

~~18.264~~18.266 An example of such work can be found in the EU-KLEMS project, which can be found on the project site <https://www.rug.nl/ggdc/productivity/eu-klems/>.

## G. International price and volume comparisons

### 1. Introduction

~~18.263~~18.267 Users want to compare GDP and its components not only over time for a given country or countries in analyzing economic growth, for example, but also across countries for a given time period in analyzing relative economic size. A commonly used method of making such comparisons is to adjust national accounts values to a common currency using exchange rates, which has the advantage that the data are readily available and completely up to date. This is adequate if users need a ranking of a country's relative spending power on the world market. However, it is not adequate for comparisons of productivity and standards of living because it does not adjust for the differences in price levels between countries and thus does not give a measure of countries' relative sizes in the volume of goods and services they produce.

~~18.264~~18.268 Purchasing power parities (PPPs) are used in producing a reliable set of estimates of the levels of activity between countries, expressed in a common currency. A purchasing power parity (PPP) is defined as the number of units of B's currency that are needed in B to purchase the same quantity of individual good or service as one unit of A's currency will purchase in A. Typically, a PPP for a country is expressed in terms of the currency of a base country, with the US dollar commonly being used. PPPs are thus weighted averages of the relative prices, quoted in national currency, of comparable items between countries. Used as deflators, they enable cross-country comparisons of GDP and its expenditure components.

~~18.265~~18.269 This section first examines the index number issues in aggregate comparisons of prices and

volumes across countries. The ICP produces internationally comparable economic aggregates in volume terms as well as PPPs and price level indices (PLIs). Established in 1968, the ICP has grown to cover all regions of the world [in combination](#) with the OECD/Eurostat PPP program.

~~18.266~~18.270 Compiling PPP-based data is a costly and time-consuming exercise, so it is not possible to make such comparisons as a matter of course. Worldwide coordination is required to collect the data and compile the PPP-based estimates. However, national accountants in participating countries need to understand the basic principles of the comparison and the practical demands that are made on them for data to compile PPP indices and thus GDP volume comparisons. This material is the subject of the last part of this section.

## 2. Index number issues

~~18.267~~18.271 The theory of index numbers developed in a time series context cannot be applied mechanically to international comparisons simply by replacing the term “period” by the term “country.” International comparisons differ in a number of respects.

- a. Time series are ordered by the date of the observation, but countries have no such a priori ordering. In consequence there is no predetermined way to order countries when compiling chain indices.
- b. For international price comparisons different price collectors will be reporting on the prices of the items in different countries. There thus is a need for flexible but detailed structured product descriptions (SPDs) for each item so that only the prices of like items are compared, either by comparing the prices of exactly the same item specification drawn from the SPD in both countries, or by adjusting the prices of different specifications drawn from the SPD for quality differences.
- c. International comparisons are conducted on a less regular basis, in part because they present a large scale coordination challenge, involving the statistical offices of all participating countries as well as international organizations.

~~18.268~~18.272 At the heart of the PPPs are price comparisons of identical or closely similar product specifications. The 2005 ICP round used SPDs to define these specifications and to ensure the quality of the detailed price comparisons. For each item there is a specification describing the technical characteristics of the item in detail so a price collector can precisely identify it in the local market. Besides the technical characteristics, the specification also includes other variables that need to be considered when pricing the item, such as the terms of sales, accessories and transportation and installation costs. The database formed from these structured descriptions and the prices collected for them permit more precise matching of items between countries.

### Representativity versus comparability

~~18.269~~18.273 Two critical criteria in selecting products to be priced for calculating PPPs are “representativity” and “comparability”. Representative products are those products that are frequently purchased by resident households and are likely to be widely available throughout a country. Representativity is an important criterion in the ICP because the price levels of non-representative products are generally higher than those of representative products. Therefore, if one country prices representative products while another prices non-representative products in the same expenditure category, then the price comparisons between the countries will be distorted. On the other hand, comparability relates to the physical characteristics of a product. Products are considered to be comparable if their physical characteristics, such as size and quality, and economic characteristics, such as whether candles are used as a primary source of light or are primarily decorative, are identical.

~~18.270~~18.274 In practice, difficult trade-offs are involved in selecting products that are both representative and comparable to use in calculating PPPs. The product lists for calculating PPPs are developed in a way that balances the competing aims of within-country representativity and cross-country comparability. In this respect, they are generally quite different from the products that would be priced by any individual country to compile its price indices (such as the consumer price index or any of a range of producer price indices) and which are used in producing the deflators used to calculate volume estimates in the time series national

accounts. In the case of time series within a country, representativity is the key criterion in selecting the products to be priced while comparability with other countries is unimportant. Once a representative product is selected for pricing, the important issue is to price the same product in subsequent periods so that price changes in the product can be measured over time. For the ICP, representativity is required only at a point in time and not over time

## Aggregation

~~18.271~~18.275 PPPs are calculated and aggregated in two stages: estimation of PPPs at the level of basic headings and aggregation across basic heading PPPs to form higher-level aggregates. The estimation of basic heading level PPPs is based on price ratios of individual products in different countries. Typically no information about quantities or expenditures is available within a basic heading and, thus, the individual price ratios cannot be explicitly weighted when deriving PPPs for the whole basic heading. Two aggregation methods dominate PPP calculations at this level, the [GEKS](#) method (described below) and the Country Product Dummy (CPD) method. A description of these methods can be found in chapters 4 and 5 of *Measuring the Real Size of the World Economy*. Weights are of crucial importance at the second stage when the basic heading PPPs are aggregated up to GDP. The main approaches used in the aggregation are summarized in the paragraphs below.

**Commented [ED23]:** Changed to match abbreviation used in latest ICP methodology documents.

## Binary comparisons

~~18.272~~18.276 As outlined in section C, the monetary value of GDP, or one of its components, ( $I_t$ ) reflects the combined differences of both price and quantities, that is:  $LP \square PQ \square IV$  or  $LQ \square PP \square IV$ . Price and volume indices may be compiled between pairs of countries using the same kinds of index number formula as those used to measure changes between time periods. A Laspeyres-type price index for country B compared with country A is defined as:

$$L_p = \sum_{i=1}^n \left( \frac{p_i^B}{p_i^A} \right) s_i^A \equiv \frac{\sum_{i=1}^n p_i^B q_i^A}{\sum_{i=1}^n p_i^A q_i^A} \quad (20a)$$

and a Paasche-type index as:

$$P_p = \left[ \sum_{i=1}^n \left( \frac{p_i^A}{p_i^B} \right)^{-1} s_i^B \right]^{-1} \equiv \frac{\sum_{i=1}^n p_i^B q_i^B}{\sum_{i=1}^n p_i^A q_i^B} \quad (20b)$$

where the weights  $s_i^A$  and  $s_i^B$  are component shares of GDP at current values of countries A and B.

~~18.273~~18.277 Given the complementary relationships between Laspeyres and Paasche price and volume indices noted earlier, it follows that a Laspeyres-type volume index for B compared with A can be derived by deflating the ratio of the values in B to A, each expressed in their own currencies, by the Paasche-type price index (20b). A Paasche-type volume index is similarly derived by deflating the ratio of values of B to A by a Laspeyres-type price index (20a).

~~18.274~~18.278 The differences between the patterns of relative prices and quantities for two different countries tend to be relatively large, compared with those between time periods for the same country. The resulting large spread between the Laspeyres- and Paasche-type intercountry price and volume indices in turn argues for an index number formula, such as Fisher, that makes symmetric use of both country's price and quantity information.

## Multilateral comparisons

~~18.275~~18.279 The need for multilateral international comparisons may arise, for example, to determine GDP aggregates for blocks of more than two countries or rankings of the volumes of GDP, or per capita GDP,

for all the countries in a block. It is desirable that such rankings are transitive.

### Transitivity

~~18.276~~18.280 Consider a group of  $m$  countries. As binary comparisons of volumes and prices may be made between any pair of countries, the total number of possible binary comparisons is equal to  $m(m-1)/2$ . Let the price, or volume, index for country  $j$  based on country  $i$  be written as  $iI_j$ . A set of indices is said to be transitive when the following condition holds for every pair of indices in the set:

$$iI_j \times iI_k = iI_k \quad (21)$$

This condition implies that the direct (binary) index for country  $k$  based on country  $i$  is equal to the indirect index obtained by multiplying the direct (binary) index for country  $j$  based on country  $i$  by the direct (binary) index for country  $k$  based on country  $j$ . If the entire set of indices is transitive, the indirect indices connecting pairs of countries are always equal to the corresponding direct indices. In practice, none of the standard index formulae in common use, such as Laspeyres, Paasche or Fisher, is transitive.

~~18.277~~18.281 The objective is to find a multilateral method that generates a transitive set of price and volume measures while at the same time assigning equal weight to all countries. There are four quite different approaches that may be used. The first approach achieves transitivity by using the average prices within the block to calculate the multilateral volume indices. The second approach starts from the binary comparisons between all possible pairs of countries and transforms them in such a way as to impose transitivity. The third method uses regression techniques to estimate missing prices by using price relatives for other products on a country-by-country basis. The fourth method is a multilateral chaining method based on linking bilateral comparisons such that countries that are most similar in their price structures are linked first.

### The block approach

~~18.278~~18.282 The most widely used form of the block approach uses the average prices of the block to revalue quantities in all countries in the block. This automatically ensures transitivity. The volume index for country B relative to country A is defined in the first expression in equation (20) as:

$$GK_Q = \frac{\sum_{i=1}^n \bar{p}_i q_i^B}{\sum_{i=1}^n \bar{p}_i q_i^A} = \frac{\sum_{i=1}^n \bar{p}_i q_i^C}{\sum_{i=1}^n \bar{p}_i q_i^A} \times \frac{\sum_{i=1}^n \bar{p}_i q_i^B}{\sum_{i=1}^n \bar{p}_i q_i^C} \quad (22)$$

and can be seen to be transitive. The average price  $\bar{p}_i$  for each individual good or service is defined as its total value in the block, expressed in some common currency, divided by its total quantity:

$$\bar{p}_i = \frac{\sum_{j=1}^m c^j p^j q_i^j}{\sum_{j=1}^m q_i^j} \text{ where } \sum_{j=1}^m q^j = \sum_{j=1}^m \frac{v^j}{p^j} \quad (23)$$

~~18.279~~18.283 The most common block method is the Geary Khamis (GK) method in which the currency converters used in (23) are the PPPs implied by the volume indices defined by (20). In this method, the average prices and PPPs are interdependent being defined by an underlying set of simultaneous equations. In practice, they can be derived iteratively, initially using exchange rates as currency converters for average prices, for example. The resulting volume indices are then used to derive the implied set of PPPs, which are themselves used in turn to calculate a second set of average prices, volume indices and PPPs, etc.

~~18.280~~18.284 The advantages of a block method such as the GK method include:

- The block of countries is recognized as an entity in itself;

- b. The use of a single vector of prices ensures transitivity and the volume measures are additively consistent and can be presented in value terms using the average prices of the block (it is possible to present the results for a group of countries in the form of a table with countries in the columns and the final expenditure components in the rows, in which the values add up in the columns as well as across the rows); and from them a set of  $m-1$  transitive indices that resemble the original Fisher indices as closely as possible, using the least squares criterion. Minimizing the deviations between the original Fisher indices and the desired transitive indices leads to the so-called GEKS formula, proposed independently by Gini, Elteto, Koves and Szulc.
- c. It is possible to compare ratios, such as the shares of GDP devoted to gross fixed capital formation, because the same vector of prices is used for all countries.

18.281 18.285 However, comparisons between any two countries, based on the multilateral block results, may not be optimally defined. It was shown in the description on transitivity that best practice price and volume comparisons between countries A and B should make symmetric use of information on their prices and quantities. If A's relative prices are higher than average and B's are lower, the use of average prices decreases A's expenditures expressed in average international prices and increases those of B relative to a country whose prices are close to the international average. Such a disparity is often noted in the case of services between developed and developing countries. Consequently, when using the GK method, PPP-based expenditures are generally overstated for poor countries.

#### *The binary approach*

18.282 18.286 An alternative approach to the calculation of a set of multilateral volume measures and PPPs is to start from the binary comparisons between all possible  $m(m-1)/2$  pairs of countries. If each binary comparison is considered in isolation, the preferred measure is likely to be a Fisher index.

18.283 18.287 Fisher indices are not transitive but it is possible to derive and the summation is over the  $m$  different countries in the block. The term  $c_j$  in expression (23) is a currency converter which could be either a market exchange rate or a PPP used to convert each country's expenditure on item  $i$ ,  $v_i \square p_i q_i$  into the common currency.

18.284 18.288 The GEKS index between countries  $i$  and  $k$  is the geometric average of the direct index between  $i$  and  $k$  and every possible indirect index connecting countries  $i$  and  $k$ , in which the direct index is given twice the weight of each indirect index. Transitivity is achieved by involving every other country in the block in the GEKS index for any given pair of countries.

18.285 18.289 The GEKS index:

- a. provides the best possible transitive measure for a single aggregate between a pair of countries, in much the same way as a chain Fisher index may provide the best possible measure of the movement of a single aggregate over time;
- b. gives equal weights to the two countries being compared; and
- c. is not affected by the relative sizes of the countries, a desirable attribute.

However, the consequences are similar to those for chain indices in a time series context. It is not possible to convert the GEKS volume indices for an aggregate and its components into a set of additively consistent values. This is in contrast to the GK method.

#### *Ring comparisons*

18.286 18.290 The outline of the above methods assumes that there is one set of comparisons comprising all the countries in a block. As the number of countries participating increases, it becomes difficult to administer them as a single group. Moreover, it is difficult to find items that are both nationally representative and globally comparable at the same time for countries far apart both geographically and in their level of

development. There are thus advantages to a regionalized approach to the compilation of PPPs. Product specifications are prepared for each region and independent sets of PPPs prepared for countries on a region by region basis.

~~18.287~~18.291 While this approach probably improves the quality of PPPs at the regional level, there is still the need to combine the regions to obtain a global comparison. Traditionally, a “bridge country” was chosen to provide the link between regions. The bridge country participated in the price surveys of more than one region. The ring approach extends this idea and identifies a subset of countries in each region to act as “ring countries”. These countries comprise a synthetic “region” that intersects with all of the regions whose comparisons are to be linked together. A global core list is added to the regional lists of goods and services for the main price survey on household consumption. This common list provides the basis to link the within-region PPPs across regions. Each region decides which elements of the core list will be part of its regional data collection. Thus, every country’s data is used to estimate the between-region linking factors.

~~18.288~~18.292 The method chosen depends on a number of factors including the purpose of the analysis, level of aggregation, sparseness of data, whether the aggregation is within regions, across ring countries, or for the whole data set and the importance attributed to additivity and symmetric treatment of countries.

### 3. Practical considerations for national accountants

#### PPP and the national accounts

~~18.289~~18.293 One of most important uses of PPPs is to calculate comparable estimates of GDP and its major components, expressed in a common currency where the effects of differences in price levels between countries are removed. The national accounts are integral to PPP estimates in three ways. In the first place, the national accounts provide the weights that are used to aggregate prices from a detailed level to broader aggregates, up to GDP itself. Secondly, the national accounts provide the values that are “deflated” by the PPPs to provide the volumes (also referred to as “real expenditures”) expressed in a common currency that enable GDP and its expenditure components to be compared between countries. Thirdly, comparisons can be made of aggregates below the level of GDP.

~~18.290~~18.294 The PPP exercise also produces comparative price level indices (PLI). A PLI is the ratio of the PPP for a country relative to the official exchange rate, both measured with respect to a reference currency. PLIs are generally expressed on a base of 100, with the base being either a single reference country or a regional average.

~~18.291~~18.295 If a country has a PLI less than 100, then its price level is lower than the numeraire country (or region). Similarly, any pair of countries can be compared directly. If one has a PLI less than the other, then the country with the lower PLI would be considered “cheap” by the other country, regardless of whether its PLI is above or below 100.

~~18.292~~18.296 In practice, PPPs do not change rapidly over time and so a large change in a country’s PLI is usually due to a large change in exchange rates.

~~18.293~~18.297 PPP-based volumes are often expressed as “time series”, which they are not. Each year is a comparison between countries in isolation from other years. It is important that the volumes in the ICP not be confused with the time series volumes described earlier in this chapter because they are different measures, although there are some similarities in that they are both designed to measure values that have had the direct effects of price differences removed from them. In a time series of volumes, the effects of price changes from one period to another are removed to produce the volume measures from which rates of economic growth are calculated. In the case of an intercountry comparison, which is the basis for PPP-based volume measures, the effects of differences due to exchange rates and those due to different price levels within each country are removed from the national accounts values to provide a comparison between the volumes in the countries concerned.

~~18.294~~18.298 The lowest level for which PPPs can be compared across all countries involved in a comparison is referred to as the “basic heading” and it is also the lowest level for which national accounts values are required as weights. In effect, the national accounts values provide the weights to aggregate the basic heading level data to broader national accounting aggregates, including GDP itself. The basic heading is

also the level at which product specifications are determined, with a number of products representative of the expenditure within each basic heading being specified for pricing.

~~18.295~~18.299 Expenditure-based estimates of GDP have been used in most PPP-based comparisons during the past half-century or so because the prices for final expenditures are more readily observable than those for outputs and inputs, which would be required for a comparison of the production-based estimates of GDP. Consistency in the national accounts is critical in producing comparable estimates across countries so the SNA has played an important part in PPP-based comparisons by providing the framework for obtaining consistent estimates of GDP and its major aggregates.

~~18.296~~18.300 The ICP is the broadest-based project to produce PPPs; the volume estimates produced from the ICP present a snapshot of the relationships between countries from all over the world, expressed in a common currency. The ICP is a very expensive and resource-consuming project and so it provides benchmarks at infrequent intervals. As a result, PPP benchmarks from the ICP have to be extrapolated using time series from the national accounts of the countries involved. It is interesting to compare the outcomes of an extrapolation with the benchmarks from two sets of PPPs compiled several years apart. In practice, the extrapolated series do not tie in exactly with the benchmarks and there are several reasons for the differences that arise. An important one is the issue of the consistency between the prices used in the time series national accounts and those used in calculating PPPs as explained in the section on representativity and comparability earlier. Further, the price and volume structure may change significantly over time in a way not picked up in the extrapolation techniques.

### Why ICP growth rates differ from national growth rates

~~18.297~~18.301 The method commonly used to extrapolate PPPs from their benchmark year to another year is to use the ratio of the national accounts deflators from each country compared with a numeraire country (generally the United States of America) to move each country's PPPs forward from the benchmark. The PPPs derived are then applied to the relevant national accounts component to obtain volumes expressed in a common currency for the year in question.

~~18.298~~18.302 Theoretically, the best means of extrapolating PPPs from a benchmark year would be to use time series of prices at the individual product level from each country in the ICP to extrapolate the prices of the individual products included in the ICP benchmark. In practice, it is not possible to use this type of procedure in extrapolating PPP benchmarks because the detailed price data needed are not available in all the countries. Therefore, an approach based on extrapolating at a macro level (for GDP or for a handful of components of GDP) is generally adopted. Leaving aside the data problems involved in collecting consistent data from all the countries involved, a major conceptual question arises with this process because it can be demonstrated mathematically that it is impossible to maintain consistency across both time and space. In other words, extrapolating PPPs using time series of prices at a broad level such as GDP will not result in a match with the benchmark PPP-based estimates even if all the data are perfectly consistent.

~~18.299~~18.303 One of the reasons for differences between GDP time series and PPP benchmark comparisons stems from the definition of a product. As explained in paragraphs 18.66 to 18.67, location is an essential product characteristic in the national accounts whereas the PPP comparisons use average prices of the whole country. Another problem is that the weighting patterns underlying the deflators in the time series national accounts will differ from those in the PPP benchmarks over time. In addition, as noted above, the products priced for the PPPs will differ from those underlying the time series because of the requirements in spatial price indices for representativity within each country and comparability between countries, while in time series the main requirement is for consistency over time. Generally, many more products will be priced for a country's price indices than it is possible to price for calculating PPPs. Finally and often most critically, the prices underlying the deflators in the national accounts are adjusted to remove changes in quality over time and the methods of making such quality adjustments can differ significantly between countries. In particular, the extent of using hedonic methods for adjusting products whose characteristics change rapidly varies significantly from country to country. Electronic products (such as computers) feature prominently in hedonic quality adjustment, although some countries also use hedonics to quality adjust products such as clothing and housing. Comparing price changes in a country that uses hedonics in quality adjusting the price indices underlying its national accounts deflators with those in one that does not do so will lead to potentially

**Formatted:** Font: (Default) +Headings CS (Times New Roman), 10 pt, Complex Script Font: +Headings CS (Times New Roman), Don't snap to grid, Highlight

large inconsistencies between the benchmarks and the extrapolated series.

~~18.300~~18.304 Possibly the single biggest factor that affects the difference between extrapolated GDP series and PPP benchmark results is due to exports and imports. GDP volume measures in the national accounts are unaffected by changes in terms of trade whereas they influence real GDP in spatial comparisons directly. For example, an increase in energy prices results in an increase in nominal GDP. In a spatial comparison, the outcome will be an increase in GDP volumes for energy exporting countries relative to other countries because the net trade PPPs are based on exchange rates, which do not respond to a change in the terms of trade to a significant extent in the short term. The result is that the increase in the terms of trade is treated as a volume effect in the PPP-based benchmark. On the other hand, in the national accounts of energy exporting countries, GDP volumes remain unchanged if the same amount of energy is exported and so the increase in the terms of trade is treated as a price effect, which is observed in the GDP deflator used as the price extrapolator.

### Non-market services

~~18.301~~18.305 Another area that leads to consistency problems between countries' PPP-based volumes is the group of so-called "comparison-resistant services". They are predominantly (although not exclusively) non-market services, with government services being a major part of the non-market services that have to be priced for PPP projects. The main problems in pricing non-market services relate to the quality of the services being produced and the productivity of the labour used in producing them. One of the conventions used in producing the estimates for the government sector in most countries' national accounts is that the value of output is measured as the sum of the labour and material inputs used in producing the service(s), which involves an assumption that an increase in costs translates into an equivalent increase in output. In addition, when output indicators are not available, an assumption that is sometimes made in the national accounts is that the productivity of the labour involved in producing such services does not change over time either. A similar assumption, that productivity is identical in all the countries in a comparison, generally has to be made between countries in calculating PPPs. It is a reasonable assumption when countries at roughly the same level of economic development are involved in the PPP comparison. However, when countries at very different levels of economic development are being compared then the validity of the assumption breaks down.

~~18.302~~18.306 The choices faced by the compilers of PPPs are either to assume that productivity levels are identical across countries, even when they are at very different stages of economic development, or to adjust the non-market services estimates in some way to account for productivity differences. Apart from the problems involved in determining an appropriate conceptual approach to adjust for productivity differences between disparate economies, obtaining the data required to make such adjustments also proves problematical particularly when the method involves adjustments based on relative levels of capital intensity in the countries involved. Despite the problems, it is sometimes necessary to make productivity adjustments for non-market services because the problems involved in doing so are rather less than the consequences of assuming equal productivity in all the countries in a comparison.

### Conclusion

~~18.303~~18.307 PPP-based comparisons of activity levels between countries are an important use of national accounts. Despite the conceptual and empirical difficulties, PPP-based volumes provide a much firmer basis for international comparisons than the commonly used alternative of converting national accounts aggregates to a common currency using exchange rates.

## 4. Productivity comparison across countries

~~18.304~~18.308 Productivity growth is often expressed in percentage terms and comparisons across countries are made in terms of these percentages. Assuming similar methods have been used to compile the estimates for the countries being compared, and that they have roughly comparable levels of productivity, this sort of comparison is interesting and much simpler than the alternative of comparing levels. Measuring the relative

**Commented [ED24]:** New subsection drawn from paras. 19.74-19.75 of 2008 SNA.

levels of production (for example, the volume of GDP or of GDP per capita) or productivity between countries is more complicated because it is necessary to convert the national accounts data to a common currency. The best means of doing so is to calculate purchasing power parities (PPPs), which measure the rate of currency conversion that would be required to equalize the prices of a common basket of goods and services between the countries concerned. In practice, PPPs adjust for differences in price levels between countries as well as differences in exchange rates.

~~18.305~~18.309 The PPP International comparisons of productivity below the level of GDP, such as by industry, are problematic. PPPs are calculated using the expenditure-based estimates of GDP so there are no PPPs for the individual industries that contribute to GDP. Therefore, it is necessary to make an assumption that the PPP for a single aggregate such as GDP is applicable to all industries. Examining the differences in the PPPs for the various expenditure components shows they can vary significantly so this is unlikely to be a very good assumption. Making robust international comparisons of productivity at disaggregated levels is thus a very demanding exercise, though considerable progress has been made in recent years.

## Chapter 19: Summarizing, integrating and balancing the accounts (revised title and revised content)

(OLD Chapter 16: Summarizing and integrating the accounts)

### A. Introduction

- 19.1 This chapter provides a synthesis of the sequence of economic accounts presented in chapters ~~67~~ to ~~1314~~ and shows how they relate to the tables in chapter ~~23~~. It shows how the most common aggregates in the SNA, GDP, NDP, ~~and~~ GNI and NNI are related to the balancing items in the various accounts. It shows the impact on national aggregates of transactions undertaken between a resident unit and ~~a~~ resident in the rest of the world. It also describes the articulation of the accumulation accounts. The chapter ends with a section on balancing the accounts.
- 19.2 The chapter lays the groundwork for greater elaboration of the accounts, in both manners of presentation and further analysis that form the subject matter of later chapters.

### B. Integrating the accounts

- 19.3 The tables presented in ~~the previous~~ chapters 7 to 14 use a format very common in published tables; the items representing ~~resources~~revenues are shown in the right-hand side of the table and the items representing ~~uses~~expenditures in the left-hand side of the table. This format is flexible because it allows a multiple number of columns to be shown for both parts of the table and even for the two parts to be shown on different pages if the columns are sufficiently numerous. However, there is another format for the tables that is particularly useful for explanatory purposes, the T account.
- 19.4 In a T account, only one set of descriptive headings (stubs) is shown in the middle of the table with values representing ~~resources~~revenues in columns to the right and values representing ~~uses~~expenditures in columns to the left. An example of a T account is given in table ~~4619.1~~. The rows in the table show the rows from tables ~~67.1~~, ~~78.1~~, ~~79.2~~, ~~89.1~~ and ~~910.1~~ at a high level of aggregation. Data for the individual sector accounts are not shown but the total for the economy as well as for the rest of the world and the total of both these are shown. In addition, the column for the goods and services account is retained.

Table ~~4619.1~~: Summary of the current accounts in the sequence of economic accounts

#### 1. Summarizing the current accounts

- 19.5 The current accounts included in table ~~4617.1~~ consist of the production account and accounts showing the ~~primary~~ distribution of income, the ~~secondary re~~ distribution of income and the use of income. In addition to these accounts, table ~~4619.1~~ begins with imports and exports of goods and services, the entries from the rest of the world account that show the value of goods and services that ~~reach enter~~ the national economy from the rest of the world and those that are produced in the national economy but are provided to the rest of the world.

#### The production account

- 19.6 The immediately following rows show the main entries from the production account: output ~~and as well as~~ taxes less subsidies on products not already included in the value of output (see paragraph 7.59 ff) on the ~~resource~~revenues side and intermediate consumption on the ~~use~~expenditures side. The balancing item for the production account, value added, appears next, also on the ~~use~~expenditures side as the closing item of the production account. Value added is the basic building block for determining GDP.

## The generation of earned income account

- 19.7 The next few rows correspond to the generation of earned income account. This is the first part of the primary distribution of earned income account. Value added, the balancing item from the production account, appears as the only entry on the resources revenues side of the account. The entries on the left-hand side of the account under uses expenditures show how much of value added is generated by labour in the form of compensation remuneration of employees and how much of the value of output is payable to government in the form of taxes on productions less subsidies on productions, including taxes on products less subsidies on products not already included in the value of output. The balancing items, operating surplus ~~and mixed income~~, represents the contribution of capital to the generation of value added, while the balancing item mixed income represents the combination of the contribution of labour input of self-employed persons and the contribution of capital to the value added of unincorporated enterprises.

## The allocation of primary earned income account

- 19.8 In the allocation of primary earned income account, these contributions to value added appear as resources revenues of the relevant sectors; compensation remuneration of employees to households, taxes less subsidies to government and operating surplus and mixed income to the sectors containing the relevant production units. In addition, however, the allocation of primary earned income account shows how much of each of these three items is payable to non-resident units and where comparable items generated in non-resident units are payable to resident sectors.
- 19.9 In the course of production, producers may have made use of financial and non-produced non-financial assets belonging to other units. The payments for the use of these assets are shown as property income. Property income may be payable by residents or non-residents and may be receivable by residents or non-residents. Once the values for three of them are known, the value of the last is necessarily determined. For example, property income receivable by residents must be equal to property income payable by both residents and non-residents less property income receivable by non-residents. Thus property income receivable by both residents and non-residents (shown under resources revenues) must be equal to property income payable by both residents and non-residents (shown under uses expenditures).
- 19.10 The balancing items from the generation of earned income account, operating surplus and mixed income, are recorded Value added as a resource revenue on the allocation of earned income account, plus Together with the resource revenue entries of compensation remuneration of employees, operating surplus, mixed income, taxes less subsidies on production and property income, less the corresponding entries for these items as uses expenditures leads to the balance of primary earned incomes. This is the balancing item for the allocation of primary earned income account shown as an use expenditure, and the first item, a resource revenue, of the secondary distribution of income transfers other than social transfers in kind account.
- 19.11 From the balance of primary earned incomes, another key aggregate of the SNA, national income, is derived. Value added is determined by the criterion of residence; all resident units and only resident units contribute to the total. For the balance of primary earned income, however, the focus changes not just from production to income but to the residence of the units receiving the income generated by production rather than the residence of the producing units themselves. Further discussion of national income appears below in connection with the discussion of the rest of the world account.

## The ~~secondary distribution of income~~ transfers other than social transfers in kind account

- 19.12 The ~~secondary distribution of income~~ transfers other than social transfers in kind account shows how primary earned income is transformed to disposable income by the payment and receipt of current transfers. Various factors stimulate redistribution of income between sectors of the economy. One of these is the role of government in levying current taxes on income and wealth; one is the role played by social insurance schemes in redistributing contributions by current workers to retirees; another is the role of insurance in

providing a mechanism whereby small regular payments by many units are channelled to a few units suffering predefined sorts of losses. Among other types of current transfers, the role of purely voluntary transfers is of increasing interest. Such transfers may provide the main source of finance for NPISHs, in the form of international cooperation between governments, or may be between resident and non-resident households in the form of workers' remittances.

- 19.13 Current transfers payable by resident and non-resident units must be equal to current transfers receivable by both resident and non-resident units, and thus total uses and resources are equal as is the case for property income.
- 19.14 Disposable income is an important balancing item in the accounts since it shows, disregarding the impact of capital transfers, how much can be consumed without the need to run down assets or incur liabilities. It thus corresponds to the economic theoretical concept of income.

### The use of income accounts

- 19.15 The use of disposable income account shows how much disposable income is in fact used for final consumption and how much is saved. When looking at the sector accounts, the adjustment for the change in pension entitlements has to be made to ensure that these form part of the saving of households and not of pension funds. However, in the aggregate only flows relating to pension entitlements involving non-resident employees or resident employees of non-resident enterprises appear.
- 19.16 Table ~~46~~19.1 does not include the redistribution of income ~~via transfers in~~ kind account and the use of ~~adjusted~~ disposable income adjusted for social transfers in kind account but these could be inserted either in place of, or as a complement to, the income transfers other than social transfers in kind account and the use of disposable income account.

## 2. Summarizing the accumulation accounts

- 19.17 Table ~~46~~19.2 presents a summary of the accumulation accounts and balance sheets with the same degree of detail as used for the current accounts in table ~~46~~19.1. In this case, the titles given to the right- and left-hand columns are changed; the columns to the right are described as changes in liabilities and net worth, and those to the left show changes in assets.

### Table ~~46~~19.2: Summary of the accumulation accounts and balance sheets

### The capital account

- 19.18 The first items appearing on the right-hand side of the capital account are saving and the current external balance. Also appearing as ~~resources~~revenues are capital transfers receivable. By convention, capital transfers payable also appear under ~~resources~~revenues but with a negative sign. For the economy as a whole, including transactions with the rest of the world, capital transfers receivable and payable exactly offset one another in the same way that property income and current transfers do. However, this equality is not generally true for the total economy excluding the rest of the world nor for individual sectors within it.
- 19.19 Together, saving plus receivable, minus payable, capital transfers ~~(net)~~ show how much is available within the economy to acquire non-financial capital, primarily capital formation but also non-produced non-financial assets. This total is shown as a special aggregate called changes in net worth due to saving and capital transfers. It is not a balancing item but has the same characteristic of being an analytical construct of particular interest.
- 19.20 The ~~uses~~expenditures shown in the capital account are the acquisition, less disposals, of produced non-financial assets and non-produced non-financial assets, both excluding natural capital, as well as acquisitions, less disposals, of natural capital. The balancing item of the capital account is net borrowing or lending. When there is net lending, it shows the extent to which the sum of saving and capital transfers is actually used to

finance the acquisition of non-financial assets and how much is lent to the rest of the world. When there is net borrowing, saving plus capital transfers are insufficient to finance all the acquisition of non-financial assets and borrowing from the rest of the world is necessary.

### The financial account

- 19.21 The financial account shows exactly how net lending or borrowing takes place by showing all the transactions in financial instruments. Transactions in financial assets shown as changes in assets exactly balance the amounts shown as changes in liabilities ~~and net worth~~ because when all transactions of resident units with either other resident units or non-resident units are taken into account, there can be no net lending or borrowing left unexplained.
- 19.22 Because the financial account does not introduce any new balancing items and only explains how net lending or net borrowing is effected, and because it requires quite different data sources and understanding of the data sources, this account is not always compiled by national accountants. However, without the financial account, the compiler cannot be certain that the estimates for the other accounts are fully consistent and complete. Just as the national accountant must have an understanding of the balance of payments system and ensure that the transactions relating to the rest of the world are fully captured in the accounts, ~~so there is a need to have an understanding~~ ~~appreciate the implications of systems~~ of monetary and financial statistics. Two later chapters, chapters ~~2629~~ and ~~2733~~, discuss the relationships with these other statistical systems in more detail.

### 3. The goods and services account

- 19.23 Throughout the sequence of accounts, each transaction line is balanced. For the distributive and redistributive transactions, this is automatically the case if the data are fully reconciled since whatever is shown as payable by one unit must be shown as receivable by another. However this is not obviously the case for the transactions relating to goods and services. In order to preserve the balancing nature of the accounts, a column headed “goods and services” is included on each side of the accounts. In every case where there is a transaction relating to goods and services, an entry in the goods and services column on the other side of the account is made.
- 19.24 Ultimately the entries on the left-hand side of the account show the value of all goods and services supplied to the economy, either as ~~production~~ domestic output or imports, plus the taxes on products less subsidies ~~not already included in the value of output~~ ~~paid on them~~. On the right-hand side of the account, the use of the goods and services is shown, as intermediate or final consumption, capital formation or exports.
- 19.25 Clearly, ex post the total amount of goods and services supplied to the economy must be equal to the total use made of those goods and services. Setting the entries in the left-hand goods and services column equal to those in the right-hand side column gives the familiar goods and services account, described in chapter ~~4415~~:
- $$\begin{aligned} &\text{Output} + \text{imports} + \text{taxes less subsidies on products} \\ &= \text{intermediate consumption} + \text{final consumption} + \text{exports} + \text{capital formation} \end{aligned}$$
- 19.26 The equation reflects the notion that goods and services produced in the current period are used either to generate more goods and services in the current period (intermediate consumption) or to generate more goods and services in future periods (capital formation) or to satisfy human wants immediately (final consumption). However, because no economy is entirely closed, it is necessary to allow for those goods and services supplied from outside the economy (imports) and those goods and services used by other economies (exports).
- 19.27 This identity comprises the goods and services account. *The goods and services account shows the balance between the total goods and services supplied as resources to the economy as output and imports (including the value of taxes less subsidies on products not already included in the valuation of output) and the use*

*of the same goods and services as intermediate consumption, final consumption, capital formation and exports.*

#### 4. The accounts for the rest of the world

- 19.28 The entries in the integrated accounts for the rest of the world correspond to the entries in the balance of payments as laid out in *BPM76*. Table 1619.3 shows the entries for the rest of the world in the structure of the balance of payments accounts.

**Table 1619.3: Entries for the rest of the world using the *BPM76* structure of accounts**

- 19.29 There are ~~three~~four current accounts; one for goods, ~~one for and~~ services, one for ~~primary~~earned income and one for ~~secondary~~transfer income. Each of these has a balancing item but, unlike the accounts in the SNA, the balancing items do not carry down from one account to the next. However, other balancing items that do match those in the SNA are allowed for. Thus the external balance of goods, services and ~~primary~~earned income is the sum of the [external] balance of goods, ~~the [external] balance of and~~ services and the [external] balance of ~~primary~~earned incomes and corresponds to the balance of ~~primary~~earned income for the total economy. When this item is added to the external balance of ~~secondary~~transfer income, the current external balance is derived which corresponds to saving for the total economy. In this respect, it should be noted that all balancing items in the external account have an opposite sign compared to the accounts of the rest of the world in national accounts. While the national accounts record flows and positions between residents and non-residents from the perspective of non-residents, the external accounts record the relevant flows and positions from a domestic point of view.
- 19.30 In the capital account of the rest of the world, the only entries are for capital transfers receivable from and payable to the rest of the world and acquisition less disposals of non-produced non-financial assets involving non-resident units. These give the [external] capital ~~external~~account balance. When this is added to the current external balance, the result is net lending to or borrowing from the rest of the world.

#### 5. Integration of stock and flow data

##### Linking the opening and closing balance sheets

- 19.31 The balance sheets are an integral part of the SNA. An understanding of the articulation of the balance sheets with the flows relating to assets in the capital, financial and other changes in assets ~~and liabilities~~ accounts is fundamental to understanding the role capital accumulation plays in the SNA.

- 19.32 The basic accounting identity linking the opening and the closing balance sheet values for a single type of asset can be summarized as follows:

The value of the stock of a specific type of asset in the opening balance sheet valued at the prices prevailing at the date the balance sheet refers to;

*plus* the total value of the assets acquired, less the total value of those disposed of (including ~~consumption of fixed capital~~depreciation and depletion, where appropriate), in transactions that take place within the accounting period;

*plus* the value of other positive or negative changes in the volume of the assets held (for example, as a result of the discovery of a subsoil resource or the destruction of assets as a result of war or a natural disaster);

*plus* the value of the positive or negative nominal holding gains accruing during the period resulting from a change in the price of the asset;

*equals* the value of the stock of the asset in the closing balance sheet valued at the prices prevailing at the date the balance sheet refers to.

- 19.33 The value of the non-financial assets acquired, less the total value of those disposed of, in transactions that take place within the accounting period is recorded in the capital account and the value of transactions in financial assets (and liabilities) in the financial account. The value of other positive or negative changes in the volume of the assets (and liabilities) held is recorded in the other changes in the volume of assets and liabilities account. The value of the positive or negative nominal holding gains accruing during the period resulting from a change in the price of the asset (or liability) is recorded in the revaluation account. This means that the value of each entry in the closing balance sheet can, in principle, be constructed by taking the value in the opening balance sheet and adding to it the entries relating to the same asset (or liability) in each of the four accumulation accounts.
- 19.34 A nominal holding gain may be decomposed into a neutral holding gain and a real holding gain. The nominal holding gain indicates by how much the value of an asset has increased over the period. The neutral holding gain indicates the increase that would have been necessary for the asset to exactly maintain its purchasing power over the period. If the nominal holding gain is larger than the neutral holding gain, the owner of the asset has a real holding gain (equal to the difference between the nominal and neutral holding gains). If the nominal holding gain is less than the neutral holding gain, then the owner suffers a real holding loss.
- 19.35 The identity linking the opening and closing balance sheets and the accumulation account is valid even in the case of assets that are held only temporarily within the accounting period and that do not appear in either the opening or the closing balance sheets. For example, an asset may be acquired in a period, increase in price due to a holding gain and then suffer some destruction before being sold again before the end of the period.
- 19.36 The nominal holding gains and losses shown in the revaluation account include both realized and unrealized holding gains and losses but the realized holding gains and losses are incorporated in the value of transactions of the assets, leaving only the unrealized holding gains and losses in the closing balance sheet.
- 19.37 The link between the balance sheet and flow accounts in respect of financial assets and liabilities is often recognized and presented. Less attention has been focused on the links for non-financial assets though, ~~as~~ chapter 2017 on capital services makes clear, it is no less important, especially as regards an understanding of productivity growth in the economy.

## Net worth

- 19.38 The balancing item on a balance sheet is equal to the sum of all the assets less all the liabilities and is called net worth. The change in net worth between the opening and closing balance sheet can be shown to be composed of three items.
- The first of these is the change in net worth due to saving and capital transfers. This comes from the capital account and is the item shown as the total of ~~resources~~revenues on that account.
  - The second item is the change in net worth due to other changes in the volume of assets and liabilities, and is the sum of all the entries for assets, less all the entries for liabilities, in the other changes in the volume of assets and liabilities account ~~less all the entries for liabilities~~.
  - The third item is the change in net worth due to nominal holding gains and losses. This is the sum of the entries for nominal holding gains and losses for all assets, ~~recorded in the revaluation account~~ less the entries for nominal holding gains and losses on all liabilities, as recorded in the revaluation account. This can be broken down into the change in net worth due to neutral holding gains and losses and the change in net worth due to real holding gains and losses in an obvious manner.

## Asset accounts

- 19.39 The identity linking opening and closing balance sheets holds for assets (or liabilities) in total, for every separate class of asset (or liability), and indeed for every individual asset (or liability). An asset (or liability) account describes the changes in the stock of an asset (or liability) or class of assets (or liabilities) from one balance sheet to the next, itemizing which changes are due to capital transactions, which to financial

transactions and which to other changes in volume and revaluation. Asset accounts are described in chapter ~~13~~14.

## 6. Consolidating the accounts

19.40 Although it is not usual to present the accounts in a fully consolidated form, it is useful from a pedagogical point of view to consider what results from a full consolidation of the accounts.

### *Consolidating the current accounts*

19.41 All the items in table ~~16~~19.1 relating to the distribution and redistribution of income appear on both sides of the account. Their inclusion permits the derivation of significant balancing items but it is also possible to consider what entries are left if they are eliminated by consolidation. In fact what remains are the entries in the goods and services columns plus the entries for saving and the current external balance. This result can be seen from the following:

a. ~~Resources~~Revenues

- Imports 499;
- Output 3 604;
- Taxes on products 141;
- Subsidies on products -8;
- Total 4 236;

b. ~~Uses~~Expenditures

- Exports 540;
- Intermediate consumption 1 883;
- Final consumption 1 399
- Saving 427;
- Current external balance -13;
- Total 4 236.

19.42 The current external balance (-13) is equal to the external balance of goods and services (-41) plus the external balance of earned and transfer flows of income coming from the rest of the world (28). If imports, exports and the external balance of goods and services are removed from the consolidation just described, the following result can be derived:

Output 3 604

*plus* taxes on products 141

*minus* subsidies on products 8

*minus* intermediate consumption 1 883

(result 1 854)

*equals*

final consumption 1 399

*plus* saving 427

*plus* external balance of earned and transfer income ~~from the rest of the world~~ 28.

- 19.43 The first part of this identity is the definition of income generated in the economy. If the external balance of earned and transfer income from the rest of the world is regarded as an analogue to saving generated within the domestic economy, this identity can be seen as the simple economic concept that income is equal to consumption plus saving.

#### *Consolidating the accumulation accounts*

- 19.44 When the capital and financial accounts are consolidated, all the entries in the financial account are eliminated and the entries for net lending or borrowing that appear in each account cancel. All that is left is:

acquisitions less disposals of produced assets (= capital formation) (414)

~~plus the acquisition less disposals of non-produced assets (0)~~ equals

saving (427)

plus the current external balance (-13).

#### *Consolidating the rest of the world account*

- 19.45 Looking only at the capital and financial account of the rest of the world:

the current external balance (-13)

plus the acquisitions less disposals of non-produced assets (0)

plus capital transfers receivable (4)

minus capital transfers payable (1)

equals net lending or borrowing (-10).

- 19.46 Combining this identity with the previous one reduces to:

the acquisitions less disposals of produced assets (= capital formation) (414)

plus the acquisitions less disposals of non-produced assets (0)

equals

saving (427)

plus net lending or borrowing to the rest of the world (-10)

minus capital transfers payable to the rest of the world (4).

plus capital transfers receivable from the rest of the world (1).

In other words investment is equal to saving generated from within the total economy or drawn in from the rest of the world.

## **C. The macroeconomic aggregates in the SNA**

## 1. The GDP identities

19.47 Rearranging the order of items appearing in the goods and services account leads to the most familiar definitions of GDP:

Output (3 604)

*minus* intermediate consumption (1 883)

*plus* taxes less subsidies on products (141 - 8)

*equals*

final consumption (1 399)

*plus* the acquisitions less disposals of produced assets (= capital formation) (414)

*plus* exports (540)

*minus* imports (499)

*equals* GDP (1 854).

There are thus two separate ways in which GDP can be defined:

- a. *the production measure of gross domestic product (GDP) is derived as the value of output less intermediate consumption plus any taxes less subsidies on products not already included in the value of output,*
- b. *the expenditure measure of gross domestic product (GDP) is derived as the sum of expenditure on final consumption plus gross capital formation plus exports less imports.*

19.48 The production measure of GDP can also be expressed as value added adjusted to ensure all taxes less subsidies on products are included. As described in chapter 78, value added can be viewed as the elements comprising income: compensation remuneration of employees, operating surplus, mixed income and other taxes less subsidies on production. If separate estimates are available of these components, then a third way of compiling GDP is possible, that is, from the income side. Because other taxes less subsidies on production are included in value added and taxes less subsidies on products are to be included also, the two tax items can be replaced by the term that is the sum of them both, taxes less subsidies on production and imports.

GDP (1 854)

*equals*

compensation remuneration of employees (1 150)

*plus* gross operating surplus (452)

*plus* gross mixed income (61)

*plus* taxes less subsidies on production and imports (191).

The third way in which GDP can be defined is thus

- c. *the income measure of gross domestic product (GDP) is derived as compensation remuneration of employees plus gross operating surplus plus gross mixed incomes plus taxes less subsidies on both production and imports.*

## 2. A note on the valuation of output

- 19.49 In chapter 67, it is explained that the preferred measurement of output in the system is basic prices. At basic prices, the value of output excludes all taxes on products and includes all subsidies on products. It includes all other taxes on production and excludes all other subsidies on production. However, the data sources in some countries may not permit this valuation to be followed. In this case, output will be valued at producers' prices. All taxes on both products and production (possibly excluding any VAT type taxes) will be included in the value of output and all subsidies on both products and production will be excluded.
- 19.50 For this reason, the definition of GDP from the production side given above includes the phrase "plus any taxes less subsidies on products not already included in the value of output". When output is valued at producers' prices, there will be no further taxes on products to add in (except possibly VAT type taxes); they will be already included in the measure of output (and similarly subsidies on products will already be deducted). In this case, GDP may be defined as *the production measure of gross domestic product (GDP) is derived as the value of output at producers' prices less intermediate consumption*. When output is measured at basic prices (as preferred in the SNA and as followed in the numerical example) the definition can be rephrased as *the production measure of gross domestic product (GDP) is derived as the value of output at basic prices less intermediate consumption plus taxes less subsidies on products*.

### 3. Gross and net domestic product

- 19.51 While the third definition of GDP is correct both economically and statistically, it is held not to be the best measure of income. Income is usually defined as the amount that can be consumed while keeping the level of capital intact. (For further discussion on this see [paragraph 9.25 the introduction to chapter 8](#).) It is for this reason that the items ~~consumption of fixed capital depreciation and depletion~~ are so important in the accounts and appears in every account as the difference between balancing items on a gross and net basis. To measure domestic production on a net basis, it is necessary:
- to deduct ~~consumption of fixed capital depreciation and depletion~~ from the production measure of GDP,
  - to replace gross capital formation by net capital formation, and subtract depletion, in the expenditure measure of GDP,
  - to replace gross operating surplus by net operating surplus and gross mixed income by net mixed income in the income measure of GDP.
- 19.52 Each deduction from GDP is equivalent because the difference between gross and net capital formation is the ~~consumption of fixed capital depreciation, while depletion is explicitly subtracted as a stand-alone item. Both items also represent~~ as is the difference between the sum of operating surplus and mixed income on a gross basis as opposed to a net basis. Thus, *net domestic product (NDP) is defined as gross domestic product (GDP) less ~~the consumption of fixed capital depreciation and less depletion~~*.
- $$\begin{array}{l}
 \text{NDP (1 632)} \\
 \text{equals} \\
 \text{GDP (1 854)} \\
 \text{minus } \del{\text{consumption of fixed capital depreciation}} \text{ (222)} \\
 \text{minus depletion (...).}
 \end{array}$$

### 4. Gross and net national income

- 19.53 In some countries, border or seasonal workers may have a significant effect on the amount of ~~compensation remuneration~~ of employees that is either payable abroad or receivable from abroad. ~~Compensation Remuneration~~ earned abroad but repatriated to the country where the employee is resident (as opposed to where he or she works) adds to the income of households available for consumption. The concept of national income as opposed to domestic production is thus another key aggregate of the SNA. As well as

labour income from abroad in the form of ~~compensation~~remuneration of employees, income earned abroad on capital, especially financial capital, in the form of property income, is included in national income as well as any taxes ~~less subsidies on production and imports on products~~ payable by non-residents. Similar payments flowing out of the total economy to the rest of the world have to be deducted from GDP to reach national income.

- 19.54 *Gross national income (GNI) is defined as GDP plus ~~compensation~~remuneration of employees receivable from abroad plus property income receivable from abroad plus taxes less subsidies on production receivable from abroad less ~~compensation~~remuneration of employees payable abroad less property income payable abroad and less taxes plus subsidies on production payable abroad.* In the terms of an equation,

GNI (1 864)

*equals*

GDP (1 854)

*plus ~~compensation~~remuneration of employees receivable from abroad (6)*

*plus property income receivable from abroad (44)*

*plus taxes less subsidies on production-and imports receivable from abroad (0)*

*minus ~~compensation~~remuneration of employees payable abroad (2)*

*minus property income payable abroad (38)*

*minus taxes less subsidies on production and imports payable abroad (0).*

- 19.55 As mentioned above, an income concept is better measured after deducting ~~consumption of fixed capital~~depreciation and depletion, so *Net national income (NNI) is defined as GNI less ~~the consumption of fixed capital~~depreciation and depletion.*

NNI (1 642)

*equals*

GNI (1 864)

*minus ~~consumption of fixed capital~~depreciation (222)*

*~~minus depletion (...).~~*

## 5. National disposable income

- 19.56 A further step in examining the impact of the rest of the world on the national economy is to consider current transfers receivable from abroad and those payable abroad. Transfers receivable from abroad include remittances from nationals working abroad for long enough (more than one year) to be treated as resident elsewhere. However, like ~~compensation~~remuneration of employees payable from abroad, these transfers from non-residents can have a major impact on the resources available to the national economy. Overseas assistance, other than development assistance for capital projects, is also shown here. As before, transfers payable abroad must be deducted in moving from national income to national disposable income.

- 19.57 National disposable income, more often than domestic product and national income, is usually shown on a net basis. *Net national disposable income (NNDI) is defined as net national income (NNI) plus current transfers receivable from abroad less current transfers payable abroad.* In equation terms,

NNDI (1 604)

*equals*

NNI (1 642)

*plus current transfers receivable from abroad (17)*

*minus* current transfers payable abroad (55).

## D. An example set of integrated economic accounts

- 19.58 The T accounts shown in table 1619.1 and 1619.2 can be extended to cover all the sectors of the economy and as much detail as required in the accounts. Such an extended presentation is referred to as the sequencea set of (integrated) economic accounts. An example is tables 1619.4 and 1619.5 which show, simultaneously, the general accounting structure of the SNA and present a set of data for the individual institutional sectors, the economy as a whole and the rest of the world.

**Table 1619.4: Summary current account with sector details – ~~uses~~expenditures**

**Table 1619.4 (cont): Summary current account with sector details – ~~resources~~revenues**

**Table 1619.5: Summary of the accumulation accounts and balance sheets with sector details – assets and changes in assets**

**Table 1619.5 (cont): Summary of the accumulation accounts and balance sheets with sector details – liabilities, net worth and changes in them**

~~The table brings together in one presentation:~~

~~—— the institutional sector accounts,~~

~~the rest of the world accounts, and~~

~~the goods and services account.~~

- 19.59 In order to simplify this table while still having it comprehensive, classifications of sectors, transactions and other flows, assets and liabilities are at the highest level of aggregation compatible with understanding the structure of the SNA. However, columns and rows can be subdivided to introduce subsectors or more detailed classifications of transactions and other flows, assets and liabilities.

## 1. Institutional sector accounts

### Current accounts

- 19.60 As an example of the institutional sectors current accounts, consider the column for non-financial corporations.
- 19.61 The production account shows output (2 808) on the right-hand side, intermediate consumption (1 477) and value added (1 331 gross, 1 174 net, the difference referring to ~~consumption of fixed capital~~depreciation and depletion (157), on the left-hand side). Value added, the balancing item of the production account, appears again in the same row as a ~~resource~~revenue of the generation of earned income account.
- 19.62 The ~~uses~~expenditures of the generation of earned income account (~~compensation~~remuneration of employees (986) and other taxes (88) less subsidies on production (35)) are shown on the left-hand side, the balancing item being net operating surplus (135), which appears again as a ~~resource~~revenue of the allocation of primaryearned income account.
- 19.63 In the allocation of primaryearned income account, property income receivable (96), along with operating surplus is recorded on the right-hand side, and property income payable (134) is recorded on the left-hand side. It also shows, as a negative item related to rent, the reallocation of depletion to the legal owner of natural resources in proportion to its economic ownership of the resources. The balancing item is the net balance of

~~primary earned~~ incomes (97), which appears again as a ~~resource revenue~~ of the ~~secondary distribution of income~~ transfers other than social transfers in kind account. The ~~secondary distribution of income~~ transfers other than social transfers in kind account shows current transfers, payable (98) and receivable (72), leading to the balancing item of net disposable income (71). This item, which can also be described as the undistributed income of non-financial corporations, appears as a ~~resource revenue~~ in the use of income account.

- 19.64 The only transaction appearing in the use of income account for the corporations sectors is an entry for the change in pension entitlements. In this case the entry has a value of zero so the balancing item of the use of income account, saving, has the same value as disposable income.
- 19.65 The accounts for other institutional sectors may be read the same way, the relevant transactions varying according to the sector involved.

### The use of income account

- 19.66 The presentation of the two ways in which disposable income is associated with final consumption, one taking account of the redistribution ~~of income via transfers~~ in kind leading to actual consumption and the other showing final consumption expenditure to disposable income directly, is simplified in table 19.4. The ~~redistribution of income~~ social transfers in kind account and the use of ~~adjusted disposable income~~ adjusted for social transfers in kind account are merged with the use of disposable income account as follows. Disposable income, ~~net gross~~, is 317 for general government, 37 for NPISHs and 1 219 for households. Final consumption expenditure is 352 for government, 32 for NPISHs and 1 015 for households. Total consumption expenditure is 1 399. Saving is given by disposable income less final consumption expenditure.

### The accumulation accounts

- 19.67 The accumulation accounts follow the sequence of current accounts for the institutional sectors. For example, net saving of households is 192. Households receive 23 and pay 5 as capital transfers. Thus the value of the changes in their net worth due to saving and capital transfers is 210. Households have 48 as ~~gross fixed capital formation~~ acquisitions less disposals of produced assets (25 as net ~~fixed capital formation~~ after deduction of ~~consumption of fixed capital~~ depreciation (23)), changes in inventories of 2, and acquisitions less disposals of valuables of 5. Their acquisitions less disposals of non-produced non-financial assets (land) are 4. The net lending of households is 174. They incur financial liabilities (net) of 15 and acquire financial assets (net) of 189. Other changes in volume of assets and liabilities are 2. The value of the assets held by households increases by 96 due to changes in the prices of both non-financial assets (80) and financial assets (16); there are no nominal gains or losses on their liabilities, which means that all their liabilities are denominated in ~~monetary terms~~ nominal values and probably in the national currency of the economy in question.

### The balance sheets

- 19.68 The balance sheets are also part of the integrated sequence of economic accounts. In order to see the relationships between the accumulation accounts and balance sheets, take general government as the example. The opening assets are 1 185 (789 non-financial assets and 396 financial assets) and the opening liabilities 687, net worth thus being 498. The total value of non-financial assets increases by 57, which results from all changes in these assets recorded in the accumulation accounts, ~~gross fixed capital formation~~ acquisition less disposals of produced assets (excluding natural capital) (35), ~~consumption of fixed capital~~ depreciation related to these assets (-27), acquisitions less disposals of valuables (3), acquisitions less disposals of non-produced non-financial assets (excluding natural capital) (2), acquisitions less disposals of natural capital (...), depreciation and depletion related to these assets (- ...), other volume changes (0) and nominal holding gains (44). Financial assets decrease by 9 (net disposal of financial assets, 10, other volume changes, 0, nominal holding gains, 1). On the right-hand side, liabilities increase by 102, which results again

from all changes in liabilities recorded in the accumulation accounts (net incurrence of liabilities (93), other volume changes (2), revaluation of liabilities (7)). So the closing assets are 1 233 (846 + 387) and the closing liabilities are 789; closing net worth (444) shows a decrease over the year of 54. The sources of this change in net worth are summarized on the right-hand side of the account showing the change in balance sheets: changes in net worth due to saving and capital transfers (-90, see also the right-hand side of the capital account), to other changes in volume of assets and liabilities (-2, see also the right-hand side of the other changes in volume of assets and liabilities account), and to nominal holding gains or losses (38, see also the right-hand side of the revaluation account).

## 2. The rest of the world account

- 19.69 As explained earlier, the rest of the world accounts are presented from the viewpoint of the rest of the world. Imports of goods and services (499) are a resource revenue for the rest of the world, even though they represent an outflow from the national economy and exports (540) are an use expenditure of the rest of the world. Thus imports appear on the right-hand side of the table and exports on the left. The external account of goods and services is shown at the same level as the production account for institutional sectors. The external balance of goods and services is -41. With a positive sign, it is a surplus of the rest of the world (a deficit of the national economy) and vice versa.
- 19.70 As explained in connection with table 4619.3, the external balance on primary earned income is -10 and on secondary transfer income is 38, giving a current external balance of -13.
- 19.71 Transactions of the accumulation accounts appear in the columns for the rest of the world when relevant (mainly capital transfers and financial transactions). The rest of the world columns show the assets and liabilities position of the rest of the world vis-à-vis the national economy (external assets and liabilities account). The row “changes in net worth due to saving and capital transfers” corresponds, for the rest of the world, to the current external balance and capital transfers.

## 3. The goods and services account

- 19.72 In the integrated economic accounts, the goods and services account is shown in a column, not in a row. It reflects the various transactions in goods and services that appear in the accounts of the institutional sectors. Intermediate consumption and final consumption appear as uses in the institutional accounts on the left-hand side of the accounts. For the goods and services account, they appear in the right-hand side column, even though the right-hand side is generally reserved for resources revenues and consumption is a use. This device of using the opposite side of the account from normal gives a balance for the row for each of the items appearing in the goods and services account. On the resources side of the table, the figures appearing in the column for goods and services are the counterparts of the uses made by the various sectors and the rest of the world: exports (540), intermediate consumption (1 883), final consumption expenditure or actual final consumption (1 399), gross fixed capital formation acquisitions less disposals of produced assets (excluding natural capital) (376), acquisitions less disposals of produced natural capital (...), changes in inventories (28) and acquisitions less disposals of valuables (10). On the use expenditure side of the table, the figures in the column for goods and services are the counterparts of the resources revenues of the various sectors and the rest of the world: imports (499) and output (3 604). On the same side taxes less subsidies on products (133) are shown directly in the column for goods and services. They are a component of the value of the supply of goods and services that has no counterpart in the value of the output of any institutional sector.

## 4. The total economy column

- 19.73 The columns for the total economy remain to be explained. Except for taxes less subsidies on products and gross and net domestic product, the figures in these columns are simply the sum of the corresponding figures for the institutional sectors. The production account for the total economy includes, as resources revenues, output (that is, the total output of the economy (3 604)) and taxes less subsidies on products (133), the latter being the counterpart of the figure appearing on the left-hand side in the column for goods and services. The uses expenditures side of the production account for the total economy shows intermediate consumption (1

883) and domestic product at market prices (1 854 gross, 1 632 net). The latter is the sum of value added of the various sectors and taxes less subsidies on products. Domestic product then appears on the right-hand side as a resource revenue of the generation of earned income account for the total economy. Taxes less subsidies on products are shown again on the left-hand side in the column for total economy and on the right-hand side as a resource revenue of government (and the rest of the world if relevant). This double routing of taxes less subsidies on products is made in order to get domestic product, gross and net, directly in the overall accounts, as explained above.

- 19.74 The other items in the columns for the total economy are self-explanatory. Net national income at market prices (1 642) is shown directly as the sum of balance of primary earned incomes of the various sectors; national disposable income, national saving, etc. are also obtained directly.

## **E. Balancing the accounts**

19.75 As explained in more detail in section E of chapter 4, the accounting system underlying the SNA derives from the following bookkeeping principles:

- a. Vertical double-entry bookkeeping, which implies that each transaction leads to at least two entries, traditionally referred to as a credit entry and a debit entry, in the books of the transactor. As a consequence, net lending or net borrowing resulting from non-financial transactions is by definition equal to net lending or net borrowing resulting from financial transactions.
- b. Horizontal double-entry bookkeeping, which implies that each transaction of a certain unit leads to a counterpart transaction of another unit. As a consequence, for any transaction, total receipts of all units, including receipts of non-resident units from resident units, are by definition equal to total payments of all units, including payments by non-resident units to resident units. This also holds for total supply of goods and services and total use of goods and services, as explained in chapter 15 and, more concisely, in paragraph 19.47.
- c. Quadruple-entry bookkeeping, which basically combines the two principles above.

19.76 The first principle also ensures the fundamental identity of a unit's balance sheet, that is, the total value of assets equals the total value of liabilities plus net worth, i.e., net worth equals the sum of cumulative changes in net worth due to saving and capital transfers, cumulative changes in net worth due to other changes in assets and liabilities, and cumulative changes in net worth due to holding gains and losses. It also ensures, as explained in paragraph 19.32, that for a single type of asset (or liability and net worth) the difference between the opening and the closing value can be explained by the total value of the assets acquired, less the total value of those disposed of (including depreciation and depletion where appropriate) plus the value of other positive or negative changes in the volume of the assets and liabilities plus the value of the positive or negative nominal holding gains resulting from a change in the price of the asset.

19.77 The system of national accounts can thus be seen as a fully consistent and closed accounting system guided by the quadruple-entry bookkeeping principle. From a conceptual point of view, all transactions and positions of a unit/sector add up, and for all transactions (stocks), total receipts (stocks of financial assets) of all agents are equal to total payments (stocks of liabilities).

19.78 This quadruple entry bookkeeping system is not just a theoretical notion. It provides a very powerful tool for checking the quality of the data used for the compilation of national accounts, by looking at the consistency of the source data in two ways. First, one can see whether the numbers for an institutional unit or sector are internally consistent, by checking whether they respect the traditional vertical double entry bookkeeping rules. In the national accounts, this consistency is usually checked by comparing the balancing item from the capital account with the balancing item of the financial account. The other check concerns the consistency between total payments and total receipts, for each of the transactions (and positions), including total supply and total use of goods and services.

19.79 The compilation of national accounts typically involves the combination of information from a large variety of data sources. The type and quality of information available will depend on the country, but all countries

use a mix of data derived from statistical surveys, administrative data sources, financial reports, etc. These data sources may relate to particular units or sectors, or may relate to particular sets of transactions, other flows or stocks. The source information available may also differ depending on the frequency (e.g., quarterly versus annual) and the timeliness of the relevant national accounts estimates.

19.80 These data sources used as input for the compilation of national accounts are often not fully in line with the standards of the SNA, and adjustments may need to be made before integrating the results in the framework of national accounts. These adjustments may relate to differences in industry or sector coverage, conceptual differences with regard to the recording and valuation of the flows and stocks, and items that may be missing. In some cases adjustments can be made on the basis of counterpart information available from other data sources, but in other cases assumptions have to be made to fill these gaps.

19.81 The next step in the compilation process is to confront and balance the various pieces of information within the frameworks of the national accounts, be it the sequence of economic accounts for institutional sectors, the supply and use tables, or the labour market tables, in order to ensure consistency in line with the above principles. As noted above, the various data sources consist of different types of information, have undergone different types of adjustments, and differ in quality. Therefore, the balancing process can be quite complex. It often involves weighting the relative quality of the various data sources, discussing possible reasons for any differences, making decisions using informed judgement on which information to use and simultaneously adjusting the information in the framework to arrive at full consistency. Often, this is an iterative process.

19.82 To arrive at full consistency is the ideal, but this is not the practice. Usually, countries manage to compile estimates which respect the horizontal double entry bookkeeping principle, although some countries do publish, for example, different estimates for GDP from the production perspective and GDP from the expenditure perspective (particularly for quarterly estimates), thus not fully respecting the equality of supply and use of goods and services. In addition, these countries may publish yet another estimate for GDP from an income perspective.

~~19.75~~19.83 A more general phenomenon is that countries are not in a position to compile estimates which fully respect the vertical double entry bookkeeping principle for all, or most of, the institutional sectors. As a consequence, one can observe differences between net lending or net borrowing resulting from non-financial transactions versus net lending or net borrowing resulting from financial transactions. These differences are usually framed and published as “statistical discrepancies”. If such discrepancies have a structural component, in the sense of being consistently positive or negative for a certain institutional sector, there should be continued research to resolve the inconsistencies and further improving the estimates.

## **Chapter 20: Elaborating the accounts**

**(moved upwards, revised title and revised content)**

**(OLD Chapter 18: Elaborating and presenting the accounts)**

### **A. Introduction**

- 20.1 The preceding chapters explain both the accounting aspects of the SNA and the sequence of economic accounts, including supply and use tables and more detailed tables on the inputs used in the production of goods and services, labour and capital. This chapter builds on this information to describe how to elaborate the SNA in a way that better suits the needs of users.
- 20.2 Historically, the national accounts have typically been produced on an annual basis. Annual series are adequate to identify long term shifts in the economy, but to assess what is happening in the short term, higher frequency statistics – typically quarterly – fill the gap between short term indicators – typically monthly – and fully elaborated accounts and tables. Section B provides an overview of the key issues that need to be taken into consideration in producing quarterly national accounts.
- 20.3 Another important dimension of the accounts is that of regional accounts, where a region is typically a subdivision of a country. These accounts are particularly important where there are significant differences in economic circumstances between regions, and are useful for regional economic planning and development. An overview of aspects of regional accounting is provided in Section C.
- 20.4 Although no account or table in the previous chapters has illustrated it, the prime use of the SNA is in a time series context so that users of the accounts can assess how the economy is evolving and developing over time. To meet this requirement, it is essential that national accounts compilers maintain high-quality time series. Aspects associated with this are discussed in Section D.
- 20.5 A further issue to be considered in the compilation of the national accounts is that of high inflation. A method of measurement which gives acceptable approximate measures in more or less normal conditions may no longer be acceptable for countries with significant inflation. Section E describes how to handle high inflation when compiling the national accounts.
- 20.6 To explain all of the topics covered in this chapter in detail would require far more extensive discussion than is appropriate for the SNA, particularly detail regarding practical compilation issues. Accordingly, this chapter provides summary information with references, where appropriate, to manuals and compilation guidance where more detail can be found.

### **B. Quarterly national accounts**

#### **1. Introduction**

- 20.7 The main purpose of quarterly national accounts (QNA) is to provide a picture of current economic developments that is timelier than that provided by annual national accounts (ANA), and more comprehensive than that provided by individual short term indicators. In addition, as with the annual accounts, QNA provide a coordinating conceptual framework for the design and collection of economic source data and a framework for identifying major gaps in the range of available short term indicators.
- 20.8 The QNA adopt the same concepts, principles, definitions, and structure as the ANA. In principle, the QNA cover the entire sequence of economic accounts, including balance sheets, in the SNA. In practice, the constraints of data availability, time, and resources, including collection costs, mean that QNA are usually less complete than ANA. However, the compilation of the QNA should not be considered in isolation but should be coherent and consistent with the ANA. In this regard, the benchmarking of QNA series to the relevant ANA series, as described below, is an important feature of QNA compilation.
- 20.9 The coverage of the QNA system in a country usually evolves. In the initial stage of development, only estimates of GDP with a split by industry and/or type of expenditure may be derived. Gross national income (GNI), saving, and consolidated accounts for the economy often follow next. Extensions can be made as the use of the system becomes more established, data sources become available, and users become more familiar with the data. Additional breakdowns of GDP, institutional sector accounts and balance sheets, and supply and use tables may be added.

- 20.10 Detailed information on compiling QNA is available in International Monetary Fund's *Quarterly National Accounts Manual* (2017) and the material in this section is a summary of information contained in the Manual. Eurostat's *Handbook on Quarterly National Accounts* (2013) also provides guidance on the compilation of quarterly accounts.

## **2. Time of recording**

- 20.11 The general time of recording principle in the SNA is the accrual basis. This principle applies to both annual and quarterly national accounts. Under the accrual principle, flows are recorded at the time economic value is created, transformed, exchanged, transferred, or extinguished. The application of accrual principles may present specific practical and conceptual problems for quarterly flows. These situations typically arise when the monthly or quarterly statistics on which the QNA are based record flows referring to economic events that accrue to periods longer (or shorter) than a calendar month or quarter. For example, wage arrears may be recorded in a particular month although they may accrue to several past payroll periods. The accrual recording is more complicated when there is a significant delay between the reporting period and the full-accrual event, which may give rise to revisions of quarterly estimates.
- 20.12 Transactions that have a fixed relation to a particular period (e.g., accrued in a previous period or accrued over a number of accounting periods) should be allocated to the periods in which they accrued. Examples are taxes on incomes and products that may be collected in a subsequent period and employee vacation leave entitlements that build up over time and are paid when the vacation is taken. If source data are on an accrual basis then adjustments are not likely to be needed, but if they are on some other basis (e.g., cash) then adjustments should be made. For example, in the case of taxes on income and production an appropriate time shift of the tax receipts may be an approach to obtain data on a quarterly basis.
- 20.13 Uncertainty in the amount to be allocated is another element that may complicate the compilation of quarterly data on an accrual basis. For example, the amount of a tax that is paid at the end of the year may not be known at the beginning of the year. In such cases, initial estimates based on the expected amounts should be calculated, and replaced when actual amounts are known, respecting the coherence between the QNA and ANA. Similar uncertainty exists in the allocation of expected crops output.
- 20.14 Work-in-progress concerns production that goes beyond one period and the measurement of such production must be split into separate periods. Because of the shorter accounting period, these difficulties are relatively more significant for the QNA than for the ANA. In the QNA, work-in-progress should be recorded for economic activities in which the production cycle goes beyond the quarter. Work-in-progress can be particularly important for industries such as agriculture, manufacturing of ships and airplanes, and construction activities. See chapters 7 and 11 for more discussion on the measurement of work in progress.

## **3. Definitions involving a year or more**

- 20.15 The qualifying criterion for a fixed asset is that it should be used in production for more than one year. For consistency between the QNA and ANA, this period is maintained even for quarterly accounts. Similarly, the distinction between short term and long term in the classification of financial assets remains one year in the QNA.

## **4. Coverage of quarterly national accounts**

- 20.16 It is possible in principle to compile the whole set of accounts in the SNA, including balance sheets, on a quarterly basis. The most common sets of ~~quarterly national accounts~~ [QNA](#), though, are for the goods and services account, the income components of value added, government expenditure, the financial account and the balance sheet for financial assets and liabilities. The quarterly goods and services account should also be compiled in volume terms.

## **5. Measuring GDP and its components**

- 20.17 Measurement of GDP constitutes a core part of the QNA. As explained in chapter 19, there are three approaches to measuring GDP: (a) the production approach, (b) the expenditure approach, and (c) the

income approach.

- 20.18 The various approaches use specific source data and allow a distinct perspective on development and level of GDP by providing different breakdowns of GDP. They also facilitate cross-checking of data as, conceptually, the three measures should provide the same estimate of GDP. Therefore, it is recommended that countries estimate quarterly GDP using at least two of the three approaches.
- 20.19 The production approach is widely used for measuring quarterly GDP, in part because of a traditional focus in many countries on short term statistics on indicators of production, which can be used as inputs for QNA compilation. This approach involves calculating output, intermediate consumption, and value added at current prices as well as in volume terms by kind of economic activity. In most countries, output data are reasonably well covered for manufacturing, but the coverage of construction and services is usually less comprehensive. Components missing from output, intermediate consumption, and value added are typically estimated using ratios that reflect fixed coefficients; for example, intermediate consumption may be assumed to be  $\alpha$  in a fixed proportion to output in the short term. Single indicator-based estimates will be biased to the extent that the ratios vary with factors such as seasonal effects, capacity utilisation, input composition, technological change, and productivity trends.
- 20.20 The expenditure approach usually has two strong pillars of quarterly data: namely, merchandise trade and government consumption. The other categories—in particular, household final consumption—are often less well covered. The major components of external transactions are usually available from the balance of payments and through merchandise trade statistics that often have a strong basis in comprehensive data collection for customs purposes. Data on government consumption can be derived from government administrative data, but directly observed data on fixed capital formation and, in particular, changes in inventories may be lacking. Nevertheless, it may still be possible to derive a useful split of GDP by categories of expenditure. For example, if GDP is estimated using the production approach and the compiler can estimate key expenditure components using available sources, then the missing components may be presented as a residual. These could be reduced over time if more expenditure data becomes available. One such missing component may be changes in inventories, because quarterly source data are often unavailable, or otherwise incomplete or inadequate. Although not an independent check of the GDP estimates, incomplete estimates of GDP by categories of expenditure (i.e., with some components derived as a residual) are useful for analysis in addition to providing some plausibility checks of GDP.
- 20.21 The expenditure approach provides particularly useful data for business-cycle and macroeconomic policy analysis and for forecasting. Also, this approach is typically most useful for policy reasons because, over the short term, demand can generally be more easily influenced than supply.
- 20.22 The income approach avoids some of the problems that may arise in using the production and expenditure approaches, such as the reliance on fixed ratios used in production data. The income approach may have a sound underpinning in statistics on the remuneration of employees or in administrative data on this remuneration (for instance, for social security purposes). Quarterly observations of operating surplus/mixed income are often unavailable although the increasing use of business accounting software is leading to the wider availability of income data on a quarterly basis, even for many small businesses in the formal sector. Even if income data are incomplete, it may still be possible to derive an income split where one of the categories (usually gross operating surplus) is derived as a residual. The distribution of income from GDP provides a useful alternative perspective on economic development. The income approach also provides necessary data for compiling the income accounts in the sequence of economic accounts.
- 20.23 The weaknesses of the various methods for compiling quarterly GDP can be mitigated by combining production and expenditure data using the [commodity-product](#) flow method. This method is based on the fundamental national accounting identity shown in the goods and services account and supply and use tables (SUTs). The compilation of SUTs on a quarterly basis using the structures derived from the annual [supply and use tables](#) SUTs provide a coherent framework for estimating quarterly GDP in both current price and volume terms. However, not all the required data are likely to be available on a quarterly basis and various assumptions using fixed ratios are required. Nonetheless, quarterly SUTs can provide a key tool for the compilation of the QNA or, as a minimum, a validation tool to help improve the QNA. SUTs are described in detail in chapter 15.
- 20.24 Compilers of quarterly GDP should ensure that the informal economy is covered, although it may not be well represented in source data. A common assumption in the QNA is that informal activities move together with formal ones. This assumption is not always plausible across time, particularly in countries with large shares of informality undergoing rapid changes. In such cases, compilers should periodically

reassess the ratio between informal and formal activities.

- 20.25 As discussed in chapter 1, NDP measures are conceptually superior to measures of GDP, but they may be more difficult to compile in practice because of the need for estimates of depreciation and depletion. Nonetheless, compilers of QNA are encouraged to compile estimates of NDP in addition to GDP. Even when separate quarterly estimates of depreciation and depletion are unavailable, the extrapolation and interpolation of statistics discussed below can be applied to annual estimates. As these components tend to be reasonably stable in the shorter term, they lend themselves quite readily to this approach.

## **6. Quarterly accounts by institutional sector**

- 20.26 Countries are encouraged to compile quarterly institutional sector accounts. These could be introduced simultaneously or, more commonly, be gradually developed in several stages. Accounts for the general government and the financial corporations sectors may be introduced first because of the availability of source data, the analytical usefulness of the statistics, and the desirability to have the data in a national accounting framework that would allow these sectors to be linked to the rest of the economy.
- 20.27 On the other end of the spectrum, separate quarterly data for the households and NPISHs sectors are usually more difficult to obtain, and these sectors may be combined in the QNA. In the absence of direct data, indicators, such as retail sales, can be used to estimate particular components. In the absence of any source data of sufficient quality, these sectors could initially be calculated as a residual. However, given the importance of the household sector, particularly household income accounts, for the analysis of economic well-being, compilers are encouraged to develop data sources that would enable the compilation of quarterly household sector for at least the income accounts.
- 20.28 Financial accounts by institutional sector may be easier to implement than the income and capital accounts, because data on transactions and stocks of financial assets or liabilities by counterpart sectors are often available as a by-product of regulation or monitoring of the financial sector.
- 20.29 A helpful principle in compiling institutional sector accounts is making use of counterparty information: that is, in any transaction involving two parties, information can be collected from the party from which it can be most efficiently collected. For instance, data on interest payable by government to households can be obtained from one or a relatively small number of government agencies, rather than many households. Counterparty information becomes particularly important in a quarterly context when there are more likely to be gaps [in data](#). One issue to be considered is that data providers may not always be able to provide data on the institutional classification of the counterparts so some estimation may be required.
- 20.30 As previously mentioned, the income approach to measuring GDP is a foundation for the income accounts by institutional sector. The availability of data on GDP by income component and by institutional sector enables the earned income accounts to be completed by institutional sector. Thus, countries that compile quarterly estimates of GDP using the income approach typically have better-developed quarterly accounts by institutional sector.
- 20.31 Data for estimates of capital formation by institutional sector should be collected from the purchaser rather than the supplier of the capital, as the supplier may not know what institutional sector is acquiring the assets. These estimates are an important component of the capital accounts. For institutional sector data, it is necessary to cover the second-hand assets; while for the total economy, transactions in existing assets largely cancel out (except for transactions with non-residents, which can be obtained from trade and balance of payments statistics, and sales of used vehicles from businesses and governments to households). The same considerations apply to the stocks of non-financial assets for balance sheets. Similar to the stocks for the whole economy, they are likely to be stable in aggregate, although transactions in second-hand assets may be a more significant issue.
- 20.32 The financial accounts and the financial components of the balance sheets are usually among the more complete institutional sector data. Balance sheet data are often already collected from financial corporations. If the counterparts in each transaction, or financial asset or liability position are classified by institutional sectors, there is a strong basis for compiling the data for all the sectors, not only the financial corporations themselves. In addition, data from the balance of payments and the international investment position (IIP) would show transactions and financial asset and liability positions between non-residents and residents, which provide another critical element in institutional sector financial accounts.

- 20.33 Attention should also be paid to financial transactions and stocks of assets and liabilities not included in financial sector and balance of payments data, such as household equity in corporations, as well as other accounts receivable/payable or particular types of liabilities of non-financial corporation. In these cases—for example, stock exchanges and security holding databases may even provide additional information about particular types of liabilities of non-financial corporations.
- 20.34 If the accounts are derived independently, net lending/net borrowing for both the capital and financial accounts will act as checks on each other. Alternatively, if only one account is available, the balancing item can be used as a starting point for compiling the other. For a more general discussion on this point, see chapter 19.

## 7. Source data issues

- 20.35 QNA data sources are generally more limited in detail and coverage than those available for the annual estimates. QNA data sources need to be more timely than the data for the annual estimates, a factor that could affect data availability and may increase data collection costs. As a result, QNA compilation may rely on indicators that best capture the movements in the target variable in the past and in the future. Therefore, the basic principle in selecting and developing sources is to obtain indicators that best reflect the economic activity being measured. In some cases, source data are available in a form ready for use in compiling QNA with little or no adjustment. In other cases, the source data may differ substantially from the ideal and will need to be adjusted. These adjustments may typically be established-determined using ratios established in benchmark years for which additional data sources—such as the results of more comprehensive and detailed surveys or censuses—may be available. In these cases, the QNA estimates are anchored to these main benchmark years and the regular source data are used as indicators to update the benchmark estimates (extrapolation). See section D for more information on extrapolation.
- 20.36 The choice of a suitable indicator is based on the assumption that it is able to reflect the changes in the target variable. However, these indicators should be reviewed on a regular basis because the economic conditions (e.g., production relationships or price relationships of the variable) may have changed over time. The suitability of an indicator must first be assessed qualitatively by examining the similarities and differences with the target variable in terms of scope, definitions, frequency, coverage, and so forth. The most desirable indicators differ only slightly from those used in ANA, for example, by being based on a sound sample but with less detailed data. Less satisfactory are indicators that cover only a part of the total, such as the key products or a subset of producers in an industry. However, if these indicators display growth rates that are consistent with the variable being measured, then they could be quite useful. Even less satisfactory are indicators that measure a variable related to the process or population of the target variable, but less directly, such as labour inputs as an indicator of the output of market services.
- 20.37 Indicators that apply past trends or measure a variable that is connected to the target variable only by a behavioural relationship or statistical correlation should be avoided, because the underlying relationships can be expected to be less stable than is the case of an indicator with a direct intrinsic relationship to the target variable.
- 20.38 The quality of source data for QNA can be assessed by comparing growth rates derived from the sum of four quarter estimates compiled using the QNA source data with those derived from annual estimates (when the annual estimates are compiled from independent, higher-quality, source data). This should be done before the quarterly estimates are benchmarked to the annual estimates, as discussed below. If there are significant discrepancies, then ways of making improvements to the source data, or improvements in the way the source data is used in the QNA compilation should be considered. This is especially important where indicators that are used to measure a target variable by way of a ratio derived from historical relationships, as these relationships can change over time as economies evolve.

## 8. Volume and price measures

- 20.39 For consistency reasons, ANA and QNA volume data should be derived using the same formula index. Conceptually, a superlative index, such as the Fisher index, is the preferred formula for aggregating elementary price and volume indices in the QNA. An acceptable, and likely more practical, alternative is to use a Laspeyres formula for volumes with the implicit Paasche formula for prices. If Fisher indices are used, quarterly indices should be calculated using quarterly weights and chain-linked using the one quarter overlap technique. The quarterly chain Fisher series should be benchmarked to the corresponding annual chain Fisher series.

- 20.40 When the Laspeyres volume index is chosen, quarterly volume measures should be derived using annual weights from the previous year. Quarterly volume measures based on the Laspeyres formula can be chain-linked using either the one-quarter overlap, typically using the fourth quarter of the previous year as the overlap quarter, or the annual overlap technique. The one-quarter overlap technique is the best choice to preserve the time-series properties of the volume series, but should always be used in conjunction with benchmarking to remove inconsistencies with the annual chain-linked data. Instead, the annual overlap technique can be used to derive quarterly volume measures that are automatically consistent with the corresponding annual ones. When the annual overlap technique is preferred, tests should be run to verify that there are no artificial steps between years in the chain-linked series.
- 20.41 Because chain volume data in monetary terms are typically not additive, the discrepancy between chain-linked components and chain-linked aggregates should not be removed.
- 20.42 The expenditure split is generally the most practical to measure quarterly GDP in volume terms because there is a relatively clear concept of price and volume for each demand category. In contrast, the price and volume dimensions of value added are more complex because value added cannot be directly observed and quarterly data on outputs and, more probably, intermediate consumption may not be available. The income approach is not suited for price and volume measures, although some analysts may be interested in deriving estimates of real income (see chapter 18 for a description of the measurement of real incomes.) For a more comprehensive discussion of volume and price measure see chapter 18.

## 9. Seasonal effects

- 20.43 QNA series will display seasonal variations when they measure economic flows that are influenced by weather conditions, administrative reasons, trading day variations or other recurrent within-a-year patterns. These factors are often predictable. ANA variables, in contrast, do not contain seasonal patterns because the seasonal movements disappear when the quarterly data are aggregated into annual data.
- 20.44 Because users are often interested in removing predictable variation in order to highlight other changes in the series, it is common practice for QNA compilers to produce seasonally adjusted data based on well-established seasonal adjustment procedures that are described in the IMF's *Quarterly National Accounts Manual* (2017) and Eurostat's *ESS Guidelines on Seasonal Adjustment* (2015) and [Handbook on Seasonal Adjustment](#) (2018). Seasonally adjusted data retain the long term trend, the business-cycle movements, and the irregular effects in the series, but exclude seasonal and calendar effects. Simply adjusting for the number of days, or even trading days, in each period is not a substitute for seasonal adjustment as this technique does not take account of the impact of other seasonal affects.
- 20.45 Unadjusted data can also be useful in econometric models to exploit the information contained in the seasonal component of the series in modelling the dynamic relationship among the variables. In the context of QNA compilation, unadjusted series may be better suited for balancing purposes when the seasonal component is significant.
- 20.46 Seasonal adjustment procedures require that seasonal effects are relatively stable and consistent for several years; usually typically a minimum of three-five years data is required to produce quarterly seasonally adjusted estimates. Seasonal adjustment procedures do not produce accurate results when the seasonal component has an unstable and fast-evolving pattern or when it shows breaks in the seasonal pattern. Structural changes in the seasonal patterns can be handled by seasonal adjustment procedures, although experts may be needed to provide practical advice. ~~However,~~ Compilers should avoid that implausible or artificial seasonal effects are treated as true signals and passed on as such to the seasonal adjustment phase.
- 20.47 The seasonal pattern of QNA series should be checked and validated. In the assessment of seasonality, compilers should pay particular attention to possible breaks in the seasonal pattern. When these breaks are noted, it is necessary to investigate the causes behind these breaks and understand whether these events are temporary or permanent, which may influence their treatment in the seasonal adjustment procedure.

## 10. Consistency between quarterly and annual accounts

- 20.48 To avoid confusion about interpreting economic developments, it is essential that the QNA are consistent with the ANA. Differences in growth rates between QNA and ANA estimates cause confusion for users

and uncertainty about the reliability of the actual measurements. Consistency means that the sums of the non-seasonally adjusted estimates for the four quarters of the year should be equal to the annual estimates. In the situation where the ANA or ANA components are built up from the QNA, consistency is achieved by construction. The ANA may, however, be based on different sources than the quarterly estimates, and therefore, differences are expected. To overcome this issue, the non-seasonally adjusted QNA data should be aligned with the annual data using benchmarking techniques. One advantage of benchmarking is that incorporating the usually more accurate annual information into the quarterly estimates increases the accuracy of the quarterly time series. Benchmarking also ensures an optimal use of the quarterly and annual source data in a time-series context. Benchmarking is discussed further in section D.

## 11. Compilation of early estimates

- 20.49 Compilers of QNA may produce early estimates of quarterly GDP in response to a strong demand of users for a rapid measurement of macroeconomic developments, although the level of detail may be reduced due to a greater recourse to estimation methods. These early estimates are sometimes known as “flash” estimates. Early estimates typically use a similar compilation approach to that used for later estimates of the QNA, but are generally based on a partial set of source data. [In some cases, non-official data sources such as business confidence or consumer confidence might be used; however such data sources need to be used with caution as they are not direct measures of economic activity.](#) A greater use of statistical methods and assumptions is required to estimate missing observations at the time of the early estimate. In deciding the timing of early estimates, compilers should balance the trade-off between timeliness and reliability. As discussed in Section D, revisions studies should be conducted to analyse the revision process of early estimates and assess their reliability, including any early bias in the estimates. [Eurostat’s Handbook on Rapid Estimates \(2017\) provides further information on the compilation of rapid estimates.](#)
- 20.50 Related to the compilation of “flash” estimates is the emerging field of nowcasting. The advances in technology in the first part of the twenty-first century have given rise to the field of big data and the development of various data science techniques to utilize such datasets. Nowcasting involves using mathematical algorithms to estimate current trends within a short timeframe. Nowcasting high level aggregates such as GDP is fraught with challenges, but can work well when the proxy indicators are related to the target variable which might be in the case of, for example, household consumption. If nowcasting techniques are used, it is important to develop predictability analysis of the results to determine their appropriateness in compiling official statistics. However, if nowcasting techniques are not actually used in compilation, they can provide a useful tool for assessing the validity of estimates compiled using more traditional approaches.

## 12. Quarterly national accounts and short term indicators

- 20.51 The QNA are less timely than short term indicators, but they provide a more comprehensive picture of current economic developments organized in an integrated framework for analysing the data. Short term indicators such as price indices, labour market indicators, industrial production indices, and turnover data for retail trade are often available monthly, shortly after the reference period. These short term indicators provide valuable information on specific aspects of current economic developments, and may also be useful source data for compiling QNA. However, these indicators are often not based on national accounts concepts and do not provide a coherent, comprehensive, and consistent picture of the different aspects of the current economic situation. This hampers tracing the causes of current problems and identifying potential future developments. For instance, for a country facing decreasing domestic output growth, it would be helpful to identify causes such as decreasing domestic demand or falling exports and to further trace deeper causes such as income, saving, and investment patterns affecting demand categories, information on which would be available from a comprehensive set of quarterly national accounts.
- 20.52 In recent times, new non-official sources providing daily or weekly data covering specific aspects of the economy have become available. Examples include estimates of credit and/or debit card spending, road traffic data and monthly VAT collections. These so-called real time indicators are not on a national accounts basis, but can provide a very timely snapshot of particular aspects of economic activity and can be useful in compiling flash estimates.

### **13. Quarterly national accounts as time series**

- 20.53 The QNA data should be presented in a time-series format. A time series is a collection of observations ordered in time. A time-series format of QNA data is essential for a number of uses, including business and trend cycle analysis, identifying turning points, studying dynamic relationships between economic variables (in particular, leads and lags) and forecasting. The QNA should be compiled and disseminated in quarterly discrete form – i.e., as estimates for each quarter — and not in cumulative form. Cumulative data do not constitute time series. Observations based on cumulated series cannot be compared, because they measure periods of time with different length.
- 20.54 For time series recorded in a consistent manner over time, series of period-to-period changes (e.g., GDP quarter on previous quarter growth) or changes from the same period of the previous year (e.g., GDP growth between the third quarter of the current year and the third quarter of the previous year) are generally used to assess short term movements or annual trends from quarterly data. As the quarter to quarter growth rates may be influenced by changing seasonal and calendar effects, seasonally adjusted estimates should be used for assessing movements. On the other hand, growth rates calculated using changes from the same period of the previous years are unlikely to be noticeably impacted by seasonal factors and in this case seasonally adjusted data may not be needed to calculate these growth rates.
- 20.55 To further highlight the underlying trend-cycle, most standard seasonal adjustment packages also calculate a smoothed trend cycle series, representing an estimate of the combined long term trend and the business-cycle movements in the series. Further information on time series aspects of national accounts can be found in Section D.

## **C. Regional accounts**

### **1. Introduction**

- 20.56 Regional accounts, also referred to as sub-national accounts, play an important role in the formulation, implementation and evaluation of regional policies. In particular, regional indicators resulting from the regional accounts are used for assessing regional disparities. Regional accounts generally make use of the concepts of the national accounts, though there are issues at a regional level for which additional guidance is needed. Furthermore, the compilation of regional accounts creates additional practical challenges, particularly in regard to the availability of source data. For these reasons they are usually more limited in scope and detail than the national accounts.
- 20.57 A particular feature of regional accounts is that each region is treated as a different economic territory. In this context, transactions with other regions are recorded as if they are external transactions. External transactions of the region must distinguish between transactions with other regions of the country and transactions with the rest of the world.
- 20.58 Detailed information on compiling regional accounts can be found in Eurostat's *Manual on Regional Accounts Methods* (2013). This [Section](#) provides an overview of the main issues and preferred methods associated with regional accounting.

### **2. The regional economic territory**

- 20.59 The economic territory of a country is described in paragraph 5.xx). A regional economy of a country is part of the total economy of that country. The total economy is defined in terms of institutional units and sectors. It consists of all the institutional units which have a centre of predominant economic interest within the economic territory of a country. The economic territory does not coincide exactly with the geographic territory as there may be resident institutional units that undertake production outside the geographic territory. The economic territory of a country can be divided into a so-called “regional territory” and the extra-regional territory. The former consists of that part of the economic territory of a country that can be directly assigned to a region within the geographic territory of a country, including any free zones and bonded warehouses.
- 20.60 The extra-regional territory is made up of the components of the economic territory of a country which cannot be assigned to a region and consists of:
- a. The national air-space, territorial waters and the continental shelf lying in international waters over which the country enjoys exclusive rights.

- b. Territorial exclaves (i.e. geographic territories situated in the rest of the world and used, under international treaties or agreements between states, by general government agencies of the country, e.g. embassies, consulates, military bases, scientific bases etc).
  - c. Deposits of oil, natural gas etc. in international waters, outside the continental shelf of the country, operated by resident units.
  
- 20.61 Because economic activity undertaken in the extra-regional territory cannot generally be allocated to a specific region, the extra-regional territory usually appears as an additional region in the regional accounts. An alternative would be to assign the extra-territorial areas to a particular region or regions on the basis of either geographic or economic attachment.
  
- 20.62 The regional territory will be divided into regions in a way that best supports economic analysis, taking into account the availability of data to support the compilation of regional accounts. For countries that have states or provinces, these are typically used as the basis for regional accounts. Other administrative entities, such as departments or regional councils, could also be used. However, the regions do not need to be administrative entities. For example, in the European Union (EU), regional accounts are prepared on the basis of the Nomenclature of Territorial Units for Statistics (NUTS), which divides the territory of the EU for the purpose of the collection, development and harmonisation of EU regional statistics, socio-economic analysis of the regions and framing of EU regional policies.
  
- 20.63 In principle, regional accounts could be compiled at any level of disaggregation of an economic territory. In practice, the more detailed the regions, the more difficult it is to compile high quality regional accounts, particularly because source data will often not readily support detailed disaggregation. There may also be issues with data confidentiality.
  
- 20.64 As mentioned above, a full system of accounts at the regional level implies treating each region as a different economic territory. Economic transactions of both enterprises and households may cross regional boundaries. For instance, transport services and energy supply can consist of moving goods between two or more regions. Employees can earn their wages or salaries in a region different from their home region and households can spend part of their income outside the resident region. In this context, transactions with other regions are recorded as if they are external transactions. External transactions of the region must distinguish between transactions with other regions of the country and transactions with the rest of the world.
  
- 20.65 A particular issue that exists in compiling regional statistics is establishing the appropriate statistical unit. Conceptually, the establishment is the preferred unit, as it should have a local presence that can be allocated to a particular region. However, establishments do not typically have the full range of information required for compiling the full set of institutional sector accounts. Even when it comes to compiling statistics on the production of goods and services, including the inputs needed for this production, it may be problematic to estimate, for example, gross operating surplus which is typically available at the enterprise level only, and not at the establishment level. This can create challenges for compilers, which are summarised where relevant in this section. For a comprehensive discussion on statistical units, see chapters 5 and 6.
  
- 20.66 The general principle for regional accounts is that economic activity should be allocated to the region where the institutional unit undertaking the activity is resident. For households, this typically presents less difficulties, as households can generally be allocated unambiguously to a particular region. As with accounts prepared at the national level, the determination of the residence for certain types of persons, such as students and patients, requires particular consideration, and in this regard the guidance for determining residency as explained in chapter 5 should be applied at the regional level for the purpose of regional accounts.
  
- 20.67 For other institutional units, the allocation of economic activity may be less straight-forward. Three cases can be distinguished:
  - a. There are units where their centre of predominant economic interest is in one region and where their activities take place in this region. This includes corporations whose establishments are all located in the region, local and state governments, and many NPISHs.
  - b. There are multiregional units where their centre of predominant economic interest is in more than one region, but does not necessarily relate to the country as a whole. Many corporations and several NPISHs are in this situation.

- c. There are units that are solely national units, which means that their centre of predominant economic interest is not located geographically even in the sense of multiregional locations (although they may undertake activities at particular locations). This is usually the case of central government and may be the case for a small number of corporations (probably public), generally in a monopolistic or quasi-monopolistic situation, such as the national railway corporation or the national electricity corporation.
- 20.68 Assigning transactions of the units with economic activity in only a single region to a specific region does not raise any conceptual problem. Assigning the transactions of multiregional units between various regions raises more difficulties. When considering deliveries between units of the same enterprise in different regions, it is necessary to apply the recommendation in paragraph 6.xx about intra-enterprise deliveries. Such deliveries are recorded only when the receiving unit assumes responsibility for making the decisions about the level of supply and prices at which their output is delivered to the market. When this is not the case, the receiving unit is regarded as providing only a processing service to the sending unit.
- 20.69 Further, some of the transactions of multiregional units simply cannot be allocated between the different regions in which they operate. This is the case for most property income and financial transactions. Likewise, interest on the public debt payable by central government cannot be geographically located. This limits the usefulness of balancing items such as saving and net lending at the regional level (other than for households).
- 20.70 The residence principle implies, for example, that gross value added from transporting goods across several regions will not be partitioned between the regions, but allocated to the region where the production unit is resident. An example for households is that household expenditures in another region will be allocated to the region of residence of the household. Another consequence is that the value added of enterprises with establishments in more than one region will be allocated to the regions where the establishments are located and will not be allocated entirely to the head office or administrative address of the enterprise.

### 3. Commuting

- 20.71 Persons can cross national boundaries as non-resident border workers, but it is more common for persons to cross borders between regions as commuters, particularly for smaller regions and regions around metropolitan centres. Commuters can be employees or self-employed. Self-employed persons are recorded as businesses operating from the region where the self-employed person resides. According to the residence principle, commuting employees contribute to gross value added in the country and region in which the establishment where they work is resident. Thus, the regional estimates for labour costs reflect the remuneration of employees at the place of work and not at the dwelling place of the employees. As a result, commuting affects the interpretation of gross value added and GDP per head of the population. Net commuter inflows into regions increase production beyond that possible by the resident active population. Regional GDP per capita ~~appears will be~~ relatively high in regions with net commuter inflows and relatively low in regions with net commuter outflows. It may be useful to compile estimates of regional GDP per person employed.

### 4. Measuring regional GDP

- 20.72 Typically, regional gross value added at basic prices is compiled on an industry basis using either the production or income approach. (See chapter 19 for a discussion of these approaches.) If possible, the use of both approaches, compiled independently, is encouraged because it enables the two sets of estimates to be compared against each other to assist in quality assuring the results. Regional GDP is derived from regional gross value added by adding regionalised taxes less subsidies on products.
- 20.73 Conceptually, regional GDP could also be compiled using the expenditure approach. However, this approach requires information on imports and exports, which at the regional level involves transactions in goods and services between regions. Collecting this information is typically difficult in practice. However, producing regional estimates of other components of the expenditure approach, such as final consumption and gross fixed capital formation expenditures, can be very useful for analytical and policy purposes.

## 5. Regional accounts by institutional sector

- 20.74 For a range of reasons, including the difficulties of allocating property income and financial flows of multiregional and national units across regions, in most cases regional accounts are limited to recording production activities and more complete accounts for institutional sectors composed of regional units, such as households, and state and local governments.
- 20.75 There are no conceptual constraints to compiling a complete set of regional accounts for households and state and local governments, namely: the production account with gross value added as balancing item; the generation of earned income account with gross/net operating surplus and mixed income as balancing items; the allocation of earned income account with the balance of earned income as a balancing item; the income transfers other than social transfers in kind account with gross/net disposable income as balancing item; the use of income account with saving as balancing item; and the capital account with net lending or net borrowing as balancing item.
- 20.76 Regional household income accounts, in particular, can be important in understanding the economic well-being of regions and can play an important role in regional policy development. Therefore, countries that compile regional accounts are strongly encouraged to compile household income accounts. This would include highly relevant regional estimates of household final consumption in the use of income account.
- 20.77 For countries that aspire to compile regional accounts for other sectors, a reasonable solution would be to introduce a kind of national “quasi-region”, not allocated as such between the regions and being treated as an extra region. This national “quasi-region” may include the head offices of enterprises that have establishments located in, and assigned to, the regions, as well as national units.

## 6. Methods of regionalization

- 20.78 There are essentially two general methods for estimating regional aggregates – the “bottom-up” and “top-down” methods.
- 20.79 The bottom-up or ascending method of estimating a regional aggregate involves collecting data at the local establishment level or the residence of households and aggregating these values to get a regional total. The method is called “bottom-up” because the elements for compiling the aggregate are directly collected at the regional level. This method can be used for enterprises that operate in only one region, or for establishments and households if full information is available.
- 20.80 A pseudo bottom-up method can be followed where data for establishments or the residence of households are not available. Data for establishments can be estimated from enterprise data allocated using regional indicators. The estimates can then be aggregated to obtain regional totals just as in a purely bottom-up method. This method can be used especially for multiregional enterprises.
- 20.81 A technique that sits in-between a pure bottom-up approach and a pseudo bottom-up approach can be used when partial information is available for establishments. For example, information on ~~remuneration~~ remuneration of employees may be available at the establishment level, but not information on gross operating surplus. In this case, the information on ~~remuneration~~ remuneration of employees would be used directly in a bottom-up approach, and estimates of gross operating surplus at the enterprise level could be allocated to establishments in proportion to ~~remuneration~~ remuneration of employers.
- 20.82 In the top-down method a national figure from the national accounts is distributed using regional indicators which are as close as possible to the variable to be estimated. For example, remuneration of employees might be allocated to regions using the regional distribution of the total number of full time equivalents of employees, multiplied by the average annual earnings per employee from a different statistical source. This results in the regional distribution of total earnings of employees, which can be used as a regional indicator for the allocation of remuneration of employees to regions. However, indicators that allocate activity to where it takes place, rather than the region where production occurs, ~~basis~~, such as allocating the gross value added of rail passenger transport to regions according to the number of passengers transported in a region, should be avoided if possible.
- 20.83 In terms of quality and precision, the bottom-up approach is preferred, especially when the source data are available and of an acceptable quality. However, in practice, regional accounts are likely to be compiled using a mixture of bottom-up and top-down approaches depending on the availability of source data.

## 7. Volume and price estimates

- 20.84 In measuring price and volume changes, the principles applied for the national economy also apply to regions. However, there may be problems with regional data which make applying these principles to regions difficult. These include:
- a. information on regional price changes is often not available.
  - b. if regional value added in current prices is directly estimated and not by deducting intermediate consumption from output, then double deflation of regional value added is not possible.
  - c. in the absence of regional supply and use tables, price and volume changes cannot be measured and assessed in such a framework.
- 20.85 A commonly used approach is therefore to deflate regional value added by industry on the basis of national price changes by industry. This is carried out at the most detailed level at which gross value added at current prices is available. Differences between national and regional price changes due to differences in economic structure by industry are taken into account. However, this solution is still vulnerable to major differences between national and regional price changes. Examples of such differences are:
- a. Differences in cost structure, technological intensity and composition of outputs within one industry between producers in different regions. There can be large variations in price changes amongst regions for a single industry.
  - b. Regional differences in the price changes of major inputs, [for example, e.g.](#) changes in the price of labour, land and renting office space. However, the existence, for example, of national wage agreements with no regional differentiation implies that regional differences in changes in wage rates are likely small.

## 8. Regional input-output statistics

- 20.86 Regional input-output statistics comprise regional supply and use tables and the input-output tables based on them. The data in the tables improve the precision and add depth to regional accounts data. They describe the structure of production in the regions, relationships between economic activities and the dependence of regions on the product flows in other regions and abroad.
- 20.87 Regional input-output statistics form an integral part of regional accounts. Product flows described according to a consistent and logical framework add to the content of regional accounts data and enhance their quality. Supply and use tables describe the supply of products generated by production and imports in a region and the use of these products in the production of other goods (intermediate consumption), consumption as final products, capital formation and exports. The symmetrical input-output tables which are derived from supply and use tables describe interdependencies between economic activities. Analytical tables derived from them can be used to study the importance of the production and final use of economic activities to regional economy and employment.
- 20.88 Notwithstanding the benefits of compiling regional input-output statistics, they are data intensive and ideally require data for all components, including regional trade in goods and services. Generally, the full range of data is not available, so estimates of missing components are often derived using models. Due to the extent of modelling that may be required, regional input-output tables are often produced by organizations like universities or economic research institutes. Nonetheless, given the usefulness of regional input-output statistics, national statistical offices that produce regional accounts should investigate the possibility of producing regional input-output statistics. If, however, it is determined that they cannot be produced to the quality necessary for official statistics, the national statistical office should support other institutions that may be prepared to produce these statistics, or alternatively produce the statistics as experimental statistics with adequate metadata on the quality of results. Further information on supply and use tables can be found in chapter 15 and on input-output tables in chapter 36.

## **D. Time series aspects of national accounting**

### **1. Introduction**

- 20.89 Every nation's economy fluctuates between periods of expansion and contraction. These fluctuations, which are known as the "business cycle", are caused by changes in levels of employment, productivity, and the total demand for and supply of the nation's goods and services. In the short run, these changes lead to periods of expansion and contraction, often referred to as a "recession". But in the long run, in an economy with underlying growth in potential output, the peaks will be higher each time.
- 20.90 Conceptually, the typical business cycle has four phases, which progress as follows:
- Expansion: when the volume of GDP is increasing, and unemployment is typically decreasing.
  - Peak: the turning point in the business cycle at which output stops increasing.
  - Recession: when the volume of GDP is decreasing, and unemployment is increasing.
  - Trough: the turning point at which a recession ends and the volume of GDP starts increasing.
- 20.91 A major strength of the national accounts is to offer long and consistent time series, which are a necessary ingredient for monitoring the business cycle and for economic modelling and forecasting. National accounts data should be comparable over time to provide accurate measurements of short and long term economic changes. This presents two particular challenges for compilers.
- 20.92 First, high quality data sources are often available less frequently than the frequency with which the accounts are compiled. To overcome this, national accountants use data sources that are timelier, but are of lower quality. To ensure that the best use is made of source data, the higher quality data sources are introduced when they become available, and the lesser quality but more frequent data sources are integrated through a process known as extrapolation and interpolation. Underpinning this approach are benchmarking techniques, which are discussed below in sub-section 2.
- 20.93 The second challenge occurs when new concepts, methodologies etc. are introduced into the national accounts. In theory, the impact of these changes should be carried as far back as possible to avoid breaks in the series. In practice, this task is complex because the data to compile back periods under new principles may not be available or new classifications may simply not be applicable to previous periods. Consequently, it may not be possible to re-calculate back series following the same methodology used for current periods and backcasting is required. Backcasting is discussed in sub-section 3.
- 20.94 Both benchmarking and backcasting lead to revisions in national accounts series, which need to be carefully managed and explained to users. The issue of revisions is touched upon in sub-section 4.

### **2. Benchmarking**

- 20.95 Benchmarking deals with the problem of combining a series of high-frequency data (e.g., quarterly data) with a series of low-frequency data (e.g., annual data) for the same variable into a consistent time series. The two series may show different levels and movements, and need to be made temporally consistent. Because low-frequency data are usually more comprehensive and accurate than high-frequency ones, the high-frequency series is benchmarked to the low-frequency one. Benchmarking is also relevant to link the data between two comprehensive revision periods, where the national accounts are comprehensively revised say every five years.
- 20.96 Benchmarking methods should be used to derive more frequent series that (i) are temporally consistent with the less-frequent benchmarks, (ii) preserve as much as possible the movements in the indicators, and (iii) provide accurate extrapolations for periods going forward.
- 20.97 The pro rata method, which is a simple method of benchmarking, should be avoided. The pro rata method distributes the temporal discrepancies—the differences between the estimates derived from the more-frequent series and those derived from the less-frequent data—in proportion to the value of the indicator. The pro rata approach produces unacceptable discontinuities from one benchmark to the next (the so-called step problem) and therefore does not preserve the movements in the indicator from the last period before the benchmark to the period following the benchmark. Techniques that introduce such breaks in the time series seriously hamper the usefulness of the time series by distorting economic developments and possible turning points. They also [thwart hinder](#) forecasting and constitute a serious impediment for

seasonal adjustment and trend analysis.

- 20.98 To avoid the “step problem”, proportional benchmarking methods with movement preservation of indicators should be used to derive more frequent series. The preferred solution is the proportional Denton method. The proportional Denton method preserves the movements in the more frequent series as much as possible subject to the restrictions provided by the benchmarking data. As an alternative to the Denton method, the proportional Cholette–Dagum method and its variants can also be used. These benchmarking techniques are explained in detail in Chapter 6 of the IMF’s *Quarterly National Accounts Manual* (2017). As explained in the Manual, even though the chapter is focused on the quarterly-to-annual benchmarking, the principles and methods outlined apply to benchmarking of any other high-frequency to low-frequency data. [Eurostat’s ESS guidelines on temporal disaggregation, benchmarking and reconciliation \(2018\) also provide further information on this topic.](#)
- 20.99 Benchmarking should be an integral part of the national accounts compilation process and should be conducted at the most detailed compilation level. In practice, this may imply benchmarking different series in stages, where data for some series—which have already been benchmarked—are used to estimate other series, followed by a second or third round of benchmarking. The actual arrangements will vary depending on the particularities of each case.
- 20.100 To avoid introducing distortions in the series, incorporation of new benchmarking data will generally require revision of previously published higher frequency series for several years. As noted above, benchmarking methods with movement preservation (like the Denton method and the Cholette–Dagum method) minimize the impact of revisions on the historical movements of the higher frequency series.

### 3. Backcasting

- 20.101 The term “backcasting” (or “back-calculation”) relates to all the steps undertaken to reconstruct backward data using current measurement standards. The objective is to provide the user with long and consistent time series that maintains the economic history of a country. In the national accounts, a backcasting exercise is typically required at the time of a major revision for introducing methodological changes, new accounting standards, new concepts, new classifications, new benchmark years or base years, or new data sources. These revisions may lead to breaks in the time series when they cannot be applied for the entire length of the national accounts. These breaks can hamper the comparability between observations in the pre- and post-revision periods.
- 20.102 There are two general backcasting approaches: (i) the micro approach and (ii) the macro approach. The micro approach aims at recompiling the historical estimates starting from the source data at the elementary level of detail. The micro approach guarantees the most accurate results as the micro data are processed and aggregated using the new concepts, definitions, classifications etc. However, the necessary source data may not exist, or it may not be feasible to rerun the entire compilation process with available resources and time constraints.
- 20.103 In contrast to the micro approach, the macro approach aims at backcasting at more aggregate levels. The macro approach comprises statistical techniques and estimation methods that make a greater use of assumptions about how new concepts principles etc. apply to the past. These methods can make use of previously published series, indicator series or intermediate series calculated in the various steps of the national accounts compilation process. As results may differ according to the aggregation level of the data; compilers should choose the preferred detail level considering the complexity of the backcasting exercise and the quality of the recalculations. Ideally, backcasting methods should be applied at the most detailed level of the national accounts compilation.
- 20.104 In practice, countries should adopt a mix of backcasting methods that best suit their specific circumstances and needs of the particular backcasting exercise.
- 20.105 Splicing (or linking) is the simplest and most common macro backcasting method. Splicing can be used to link the new series with the old published national accounts series. The only requirement is to have an overlap between the old and new series for at least one period. The old and new series should measure as much as possible the same concept. Back data are obtained by multiplying the values of the old series by the ratio between new and old levels in the overlap period. In the case of quarterly series, the overlap period can be either the first quarter or the first year in the new series. In the former case, the new series will show the same quarter-to-quarter rates of change of the old series in the backward period. With annual splicing, the adjustment ratio is taken from the whole year; in this case, the spliced series will preserve the old annual rate for the overlap year.

- 20.106 The assumption underlying basic splicing is that the impact of the changes in the overlap period remains the same in the backcasting period. If this assumption is unlikely to hold true, alternative methods, as discussed below, should be used.
- 20.107 Quarterly splicing is the preferred approach as it provides the smoothest transition between the old and new series. However, compilers should be aware that quarterly splicing may introduce a break in the seasonal pattern if the new series presents seasonal effects that are different from those in the old series. Annual splicing could be preferable when there is a need to preserve the annual movements in the overlap period.
- 20.108 Another splicing possibility is to link gradually the old series to the new series. This approach aims at interpolating the new level of the series with a particular point in time of the backcasting period (one year or one quarter). The rates of change in the in-between periods will change accordingly. This method can be appropriate when a particular level in the old series should be preserved. This situation could arise when it is required to maintain levels of national accounts variables that had been estimated from previous benchmark revisions.
- 20.109 More sophisticated backcasting methods may be required when the assumptions underlying basic splicing techniques do not hold. For example, a more elaborated backcasting solution should be devised when there is an update of classifications. In such cases, assuming that the new series present the same movements of the old series may lead to incorrect results. New classifications may bring out items that did not exist before, or may change the way previous items were aggregated in top-level groups. Furthermore, an additional constraint for pure classification changes is that the total should not change. Bridge tables between old and new classifications should be created to help reconstruct old indicators according to a new classification. One way to reconstruct short term dynamics of new items in past periods is to estimate regression models between national accounts series and proxy indicators for those items. This approach should be used with caution as these methods rely on behavioural relationships between national accounts variables and related information that may not hold for the entire time period.
- 20.110 Another case where the assumptions underlying basic splicing may not hold is when conceptual changes are introduced. Basic splicing may lead to estimates being created for certain items for historical periods when the items simply did not exist, for example, those relating to new technologies. In these cases, it may be necessary to set a particular historical period's value at zero, and to use interpolation techniques to estimate values for subsequent periods until actual data are available.
- 20.111 A backcasting exercise should be conducted in a coordinated manner for both annual and quarterly accounts. The benchmarking methods described above can be used to realign quarterly data to annual benchmarks that are back-calculated independently.
- 20.112 One problem of consistency that may arise from the application of backcasting techniques at all levels of compilation is the lack of additivity between components and aggregates. Backcasting at detailed level has the advantage of preserving the original information for each series. However, it will show discrepancies between components and aggregates. This problem can be solved if backcasting is applied at the component level only, while the aggregate is derived as the sum of the reconstructed components. A disadvantage of this approach is that the aggregate rates of change will differ from the original ones, which may lead to confusion and criticisms from the user. The choice will also depend on the types of revision introduced. If there is a change in classifications, components that are not affected by the classification change, such as a higher level aggregate, should be preserved. However, when new methods are introduced, the aggregate levels should not be preserved.
- 20.113 Generally speaking, compilers should implement a backcasting solution that preserves as much as possible the consistency property of national accounts and, at the same time, minimizes the changes in the economic history of a country. The new backcast results must present a plausible picture of the macro-economy over the entire time series. There should be a thorough evaluation of the backcast results, including verification of the individual series and balancing items, and analysis of the revisions to both levels and growth rates of key variables.
- 20.114 Backcasting is explained in more detail in Chapter 5 of the IMF's *Quarterly National Accounts Manual* (2017)

#### 4. Revisions

- 20.115 In order to maintain high-quality, consistent time series, revisions are an essential part of good national

accounts compilation practice. They ensure that users are provided with data that are as timely and accurate as possible. Revisions are necessary to incorporate improvements in source data and methods, and the introduction of new international standards and classifications.

- 20.116 Resource constraints, in combination with user needs, cause tension between the timeliness of published data on the one hand, and reliability, accuracy, and comprehensiveness on the other. To reduce this tension, as discussed above, initial estimates are typically compiled on a timely basis, with later, revised estimates produced when more and better source data become available. Good management of the process of revisions requires the existence of a well-established and transparent revision policy.
- 20.117 It is important to emphasize that revisions are conducted for the benefit of users: namely, to provide users with data that are as timely and accurate as possible. Revisions allow new and more accurate information to be incorporated, thus improving the accuracy of the estimates, without introducing breaks in the time series. Although repeated revisions may be perceived as reflecting negatively on the trustworthiness of official statistics, delaying the incorporation of new data in the published estimates may increase the magnitude of later revisions (in particular, if these go in the same direction). Furthermore, not passing on known revisions reduces the actual trustworthiness of data even more, because the data do not reflect the best available information, and the public may know this or find this out (for instance, the public may wonder why a revision in the monthly production index is not reflected in the QNA).
- 20.118 Every so often (such as every five years), compilers of national accounts statistics, particularly compilers of QNA, should undertake a systematic analysis of the revisions that have been made to key national accounts series, such as GDP. Structural differences between initial and subsequent estimates, such as when initial estimates persistently overstate or understate later estimates, could indicate bias in the initial data sources or methods, which could be adjusted to improve the quality of the initial estimates. Significant volatility in revisions, but without a persistent pattern, could indicate that the initial data sources or methods are not of sufficient quality, and improvements to them or the use of better-quality alternatives should be investigated.
- 20.119 More information on developing a revisions policy and communicating revisions to users can be found in chapter 21.

## **E. High inflation**

- 20.120 Establishing meaningful national accounts in a country where high inflation prevails is indeed a challenge for national accounting. This challenge does not arise because those conditions create totally new national accounting problems. In fact, the same problems also exist conceptually in the very common situation of creeping inflation, with low rates of changes in the general level of prices. However, high rates of inflation exacerbate the problems. A method of measurement which gives acceptable approximate measures in more or less normal conditions may no longer be acceptable with significant inflation.
- 20.121 Basically, under high inflation the three classic roles of the currency are disrupted. The disruption in the currency's role as instrument of payment is minor; most transactions continue to be cleared in the national currency even though - sometimes legally, more often illegally - foreign currencies may be used for some domestic payments. The main difficulties are encountered in the currency's role of reserve of value. This aspect is well-known. When the annual rate of inflation is 50 per cent, for example, it is not advisable to keep any saving in the form of monetary assets, unless a mechanism of compensation against inflation is established explicitly through indexation or implicitly through high market rates of interest. Perhaps less obvious is the crisis of the currency's role as unit of account even for short periods of time. This aspect is, of course, connected with the previous one. Even within a period of one year, the value (i.e., the purchasing power) of the currency diminishes sharply when inflation is high, with the result that the sum of the values of transactions which take place at different times of the year is not at all easy to interpret. If all transactions were evenly distributed and inflation regular during the year, it could be said that the unit of account is the mid-year value of the currency. However, this condition is not fulfilled in practice. This means that under high inflation flows as conventionally measured give a distorted picture of the economic structure.
- 20.122 On certain aspects the SNA provides rules which, rigorously applied, are capable of providing correct measures. For example, rules related to time of recording transactions are essential: transactions have to be recorded at the same point in time in the various accounts in question for both transactors. Differences in the time of recording by transactors have much more serious distorting effects when inflation is high.
- 20.123 A particular and very important aspect concerns transactions and balancing items that are measured by

the difference between flows. This is the case, for example, for distribution margins measured as the difference between sales and the purchase value of the goods which are sold (the method followed in practice being very often: sales less purchases plus changes in inventories). The correct measurement of distribution margins at any point in time supposes that the purchase value of the goods sold is the price prevailing at the time the goods are sold, not at the time the purchase was actually made. In other words it means that changes in inventories have to reflect adequately the difference in value between entries to and withdrawals from inventories valued at prices at the time of entry and withdrawal, respectively (see chapter 7).

- 20.124 The measurement of value added is a very important case in point when the process of production extends over a long period of time (under high inflation “long” is usually much shorter than when inflation is low) and there is a significant lag between intermediate consumption and the recording of output. (In agriculture, for example, harvesting may even take place in a different calendar year.) In principle, the SNA provides the solution for correct measurement. It relies upon careful recording of work-in-progress. In effect, if intermediate consumption takes place mainly, for example, in the first part of the year and output (harvests or, in other cases, deliveries taken as a measure of output) is recorded mostly in the second part of the year, under high inflation value added will be overestimated. Since ~~remuneration~~ remuneration of employees is recorded when due or paid, the figure for operating surplus is heavily distorted. Of course, for agriculture if harvests occur mainly in the first half of the year and intermediate consumption in the second, the distortion is inverted.
- 20.125 The solution in such cases, in principle, is to record output progressively as work-in-progress. Then at the end of the process of production, the previously recorded work-in-progress is withdrawn from inventories after due revaluation, while from the other side the output of finished products is entered in inventories at the prices prevailing at this time. This solution shows that, basically, the right rule of recording output and inventories is the perpetual inventory method, careful attention being paid to the recording of work-in-progress. This is true for business accounts and national accounts as well. Departures from this ideal treatment cause more significant biases when inflation is high. In practice, the right solution may be difficult to apply, especially if business accounts do not provide adequate data. However, it should be approximated as far as possible, in order to minimize distortions.
- 20.126 Applying the SNA’s solutions referred to in the previous paragraphs is a means of trying to get correct measures as far as it is feasible. However, they do not solve the difficulty related to the loss of meaning of the unit of account under high inflation. Rigorously, a unit of the currency at the beginning of the year is not additive with a unit of the currency in the last months of the same year. Strictly speaking, this holds every time the purchasing power of the currency changes, even when the rate of inflation is low. However, under normal conditions (low inflation) it is assumed that over a short period of time (one year) the loss of significance of the currency as a unit of account is limited. For longer periods, this assumption is not acceptable, and comparisons are made either in volume terms (for goods and services) or in real terms (constant purchasing power of the currency). A short period of hyper-inflation involves the same measurement problems as a much longer period of low inflation.
- 20.127 As explained above, because transactions are not evenly distributed and inflation is not regular during the year, it may not be assumed that the implicit unit of account is the mid-year currency. Consequently, the economic relations are distorted. Phenomena occurring mainly in the first part of the year have their shares understated; conversely, those occurring mainly in the last part of the year have their shares overstated.
- 20.128 In order to avoid such distortions, it would be possible to use the currency at a certain point or during a short period of time (one month, for example) as the unit of account. All transactions would then be revalued at the (constant purchasing power of the) currency at the chosen point or period by applying to current values an indicator of the change in the general price level. Applying such a procedure systematically might, of course, be burdensome, but it might be appropriate to implement it for certain flows or certain aggregates only, possibly using simplified methods of calculation.
- 20.129 Because of the difficulties in interpreting national accounts in current values, one could conclude that it is useless to establish these accounts. However, they remain necessary for use in conjunction with monetary and financial variables. Further, under such circumstances more emphasis should be given to accounts covering shorter time periods. As monthly accounts are often not feasible, except for some items, quarterly accounts covering more than just GDP and its uses would be of great value for analysis. The use of the currency as a unit of account on a quarterly basis, while subject to the general criticism in principle, provides results which are easier to interpret than annual data, at least if hyper-inflation is avoided. In addition, quarterly accounts might provide a short-cut method for determining annual

accounts, using the average value of the currency in a given quarter as the unit of account.

- 20.130 Volume estimates, which play an important role in national accounting in general, are given even more emphasis for flows of goods and services and the production account when inflation is high. As far as possible it is probably appropriate to attempt to estimate volume increases directly rather than rely on deflation methods applied to current prices. In effect, the degree of approximation in the measurement of price changes may well be of the order of magnitude of the volume changes. The danger is increased when the base period for price increases is very out of date.
- 20.131 In general, frequent rebasing of national accounts in volume terms is advisable when changes in relative prices are important. In this regard, annual chain linking is encouraged. If this is not possible, the choice of the base year, which is always a delicate one, may be especially complex under high inflation due to the fact that price adjustments are irregularly timed. Studying how relative prices move in the short-, medium- and long-term in periods of high inflation, as compared with other periods, is of particular importance.
- 20.132 To assess the effects of inflation it is not sufficient to measure only flows in the current accounts and in the capital and financial accounts of the sequence of economic accounts. This is so because inflation may redistribute wealth and because changes in real wealth due to inflation may amplify or counterbalance changes in these flows. The revaluation account, which shows real holding gains and losses incurred by institutional sectors and the rest of the world according to the types of assets and liabilities they hold, is of special importance in this context.
- 20.133 Calculating these gains and losses supposes, of course, that a country has previously established sector balance sheets. Establishing sector balance sheets for financial assets and liabilities is of prime importance because the dramatic changes in the purchasing power of the currency when inflation is high undermine its role as a reserve of value. The face value of monetary assets covers a vanishing real value of these assets. For interest-bearing monetary assets and liabilities (non-interest bearing monetary assets may hardly exist when inflation is high, except at the minimum level necessary for current payments), the decrease in their real value is generally compensated, at least in part, by explicit indexation or inclusion of an element compensating for inflation in the rate of interest. This means that nominal interest, under these circumstances, can include a component which may be viewed as an anticipated reimbursement/refund of the real value of the principal of the financial liability/asset. The higher the rate of inflation, the quicker is this process of reimbursement/refund.
- 20.134 The element of compensation for inflation should not be considered as a return to capital by the lender and a current cost by the borrower. The SNA treats these components of explicit or implicit indexation as interest received and paid in the current accounts, and this treatment does not create great difficulties when inflation is low. However, the measurement of these components is essential when inflation is high if one wants to interpret correctly figures such as government disposable income or saving (or government deficit) and the corresponding figures for creditor sectors, etc. For this reason, for countries experiencing high inflation, it is recommended to show real holding gains and losses on monetary [assets](#) as memorandum items to the current accounts, in particular the earned income account. Countries with high inflation would benefit greatly from following this procedure and, in addition, giving great emphasis to a careful scrutiny of holding gains and losses in the revaluation account.
- 20.135 Going one step further, countries experiencing significant inflation may want to adjust nominal interest in order to get more meaningful measures of earned incomes, disposable income and saving of the various institutional sectors and possibly the total economy. Two main approaches may be followed:
- a. Deduct from nominal interest the amount which has been or would have been necessary in order to keep the purchasing power of the capital intact (the capital being the principal of the financial asset/liability to which the interest refers); or
  - b. Deduct from nominal interest the component of protection against inflation of the principal of the asset which is actually included in nominal interest.
- 20.136 The first approach is usually referred to as the calculation of “real interest”. Real interest is the excess of nominal interest on monetary assets over the amount which has been or would have been necessary in order to fully protect the creditor against inflation. The latter amount is calculated using an index representative of the change in the general purchasing power of the currency. When nominal interest is higher than the amount necessary to keep capital intact, real interest is positive. When nominal interest is lower than the amount necessary to keep capital intact, real interest is negative.

- 20.137 Real interest is derived from nominal interest by taking account of real holding gains/losses on the underlying assets/liabilities. For this reason, however, real interest may not be introduced in the sequence of economic accounts since it is a basic principle of the SNA that holding gains or losses should not be recorded in the current accounts of the sequence of economic accounts, but only in the revaluation account. This is true for nominal holding gains/losses (and a fortiori real holding gains/losses) on all types of assets/liabilities. Thus real interest as well as other adjustments of current incomes for real holding gains/losses may only be introduced as supplementary items, either or not in extended tables.
- 20.138 In the second approach, the component of protection of the principal of the asset against inflation which is actually included in nominal interest is deducted. Clearly the component of protection against inflation cannot, by definition, be greater than nominal interest itself; it can only be lower than or equal to nominal interest (leaving aside the service charge issue). In order to avoid any confusion with real interest from one side, and interest as currently defined in the sequence of economic accounts from the other side, let us call the excess of nominal interest over the component of protection against inflation of the principal of the asset actually included in nominal interest “interest prime”. By definition, “interest prime” may be positive or zero, but never negative.
- 20.139 Real interest and interest prime serve different purposes. Interest prime takes into account the actual influence of inflation on nominal interest, by deducting from the latter the actual component of protection against inflation of the principal of the asset which it includes. Real interest takes into account the impact of inflation on the purchasing power of the underlying assets, by deducting from the nominal interest the amount which has been or would have been necessary in order to keep the purchasing power of the asset intact.
- 20.140 Reflecting their different purposes, real interest and interest prime have different roles and places in the SNA. Real interest is a very useful analytical tool; as already stated above, it may be calculated as a supplementary item, something which is recommended for countries experiencing high inflation. Although it does not go so far as real interest, interest prime allows for a possible adjustment of nominal interest in the SNA sequence of economic accounts itself in the context of significant inflation. In the case of other property income, such as dividends, the protection against inflation of the value of the underlying asset is sought through the change in the market prices of the underlying assets, such as shares, recorded in the revaluation account. This element is not included in dividends in current terms. Thus, in terms of economic significance, the meaning of “interest prime” resembles the meaning of dividends. Both “interest prime” and dividends may then be adjusted for real holding gains/losses, outside the sequence of economic accounts, in order to get real interest or real dividends (not to be confused with interest in real terms or dividends in real terms). In terms of economic significance, the sum of dividends and holding gains/losses on shares can be interpreted as parallel to nominal interest. This shows that “interest prime” actually provides a concept whose definition is closer to the definition and measure of other property income than nominal interest.
- 20.141 Real interest and interest prime only coincide when the component of protection against inflation actually included in nominal interest is strictly equal to the amount necessary in order to give the creditor full protection against inflation. In other cases, real holding gains or losses are still experienced by debtors and creditors. They may be combined with interest prime, outside the sequence of economic accounts, in order to derive real interest.
- 20.142 For further information on accounting for high inflation, see OECD *Inflation Accounting: A Manual on National Accounting Under Conditions of High Inflation* (2003)

## Chapter 21: *BPM7 Chapter 20 / 2025 SNA Chapter 21* Communicating and Disseminating Macroeconomic Statistics (New SNA/BPM chapter) <sup>1</sup>

### A. Introduction

- 21.1 The way in which macroeconomic statistics are communicated and disseminated has a significant impact on users' understanding and utilisation of the data and should be viewed as a key component of the production chain of official statistics. Users benefit from comprehensive, consistent, accurate and reliable information communicated and disseminated on a timely basis in an accessible and understandable manner.
- 21.2 Macroeconomic statistics can be disseminated and communicated in various ways to enhance the full extent of their analytical usefulness, comparability through time and across economies, and to ensure that policy relevance is maximised. In addition, when communicating macroeconomic statistics, the terminology and presentation of the macroeconomic aggregates and concepts should, where sensible, reflect and align with the language of business, governments and the public.
- 21.3 There are various differences between countries when it comes to communicating and disseminating macroeconomic statistics. By developing consistent standards, a high degree of comparability will be achieved, in turn ~~making enabling~~ users ~~to be~~ better aware of the basis of the data (for example, which version of the SNA and BPM is used by the country) before undertaking their own analyses. At the same time, recognising the diverse needs and preferences of different user segments (e.g., policymakers, businesses, researchers and the general public) and tailoring communication strategies accordingly can further improve the relevance of macroeconomic statistics. When communicating with different user segments, different terms can be used for the same content to assist in understanding.
- 21.4 Dissemination covers the technical dimension ~~of~~ providing accessibility to data mainly to the more specialised and expert users. However, statistical dissemination and communication go beyond providing accessibility to numbers and include specific narratives, key messages, visualisations, etc. which improve the user understanding and reduce the risk of misrepresentation by users.
- 21.5 Effective statistical communication will convey a message based on facts collected from data suppliers' explanations, comments and feedback on data movements. This information will help to explain to ~~users~~ ~~readers~~ what happened, when and where something happened as well as contributing to understanding why and how it happened. ~~In some cases, this~~ However, such information may not ~~be~~ always be available from administrative data suppliers. Statistical organisations can use communication to demonstrate the relevance of their data whereby they can justify the public outlay and anticipate greater support for statistical programmes, improve relationships with data providers and gain appropriate visibility for their products.
- 21.6 This chapter aims to provide principles and guidelines for producers of macroeconomic statistics to consider together with some new recommendations to improve the way those statistics are communicated. This is to help improve comparability, understanding and the experience for the users of these statistics.
- 21.7 The chapter includes section B covering dissemination strategy and communication policy; section C covering communication with users; section D covering communication with data suppliers; section E covering statistical confidentiality; section F covering taxonomies and metadata; section G covering a framework for measuring alignment with the international macroeconomic statistical standards; section H covering prominence given to indicators other than GDP and clarification of the use of the term "net"; and section I covering the use of ~~more~~ easier to understand ~~able~~ terminology for users.

---

<sup>1</sup> The chapter is drafted as a joint SNA/BPM chapter. After global consultation and approval by the AEG/BOPCOM, only those issues that are relevant from the external sector statistics perspective will be included in BPM7.

## B. Dissemination strategy and communication policy

- 21.8 The production, analysis and dissemination of official statistics should be undertaken in a transparent and accessible way. To aid all users, information is provided through different channels (e.g., from printed releases to the use of social media) to meet different user needs and uses.
- 21.9 The dissemination policies and strategies designed by official statistics producers form part of the vision, mission, principles and values of their organisations, often available on official statistical producers' national statistical offices' and national central banks' websites and should be consistent with the underlying UN Fundamental Principles of Official Statistics<sup>2</sup>.
- 21.10 The principal aim of statistical communication is to reveal more of the information contained in statistical data (e.g., about movements in the data) and to make statistical information easier to interpret. Statistical communication is about providing factual explanations of the data in an easily understood and interesting fashion; and encouraging journalists and other users to consider how statistics might aid their analyses. Good dissemination policies support the provision of access to consistent and coherent statistical data to all users. Good dissemination practices ensure transparency and impartiality including the release of consistent and coherent data to all users at the same time according to previously announced release calendars.
- 21.11 ~~Dissemination can be through various channels and formats such as the official statistical producers' websites, printed materials and social media channels as tables, charts or raw datasets.~~ Dissemination of statistical data encompasses the use of a diverse array of channels and formats to reach a wide audience effectively. These channels include official statistical producers' websites, printed materials and social media platforms. Data can be presented in various formats such as tables, charts or raw datasets to cater to different audience preferences and needs. With new technologies, the publishing capability should support digital dissemination. This will require setting appropriate standards and policies; support for mobile devices without undermining conventional release modes; commissioning new processes; and making more data available in an open format such as comma-separated value files.

### 1. Link to the UN Generic Statistical Business Process Model

- 21.12 The statistical value chain reflects dissemination and communication as key steps with both suppliers and users. The UN Generic Statistical Business Process Model (GSBPM) describes the set of business processes that form the statistical value chain needed to produce official statistics providing a standard framework and harmonised terminology to help statistical organisations. The Level 1 stages form the highest level of the GSBPM framework and are shown in **Figure 21.1**.

**Figure 21.1 GSBPM – Level 1 stages**

~~21.13 The dissemination phase manages the release of the statistical products to users. It includes all activities associated with assembling and releasing a range of static and dynamic products via a range of channels. These activities support users to access and use the outputs released by the statistical organisation.~~

~~21.14~~ 21.13 For statistical outputs produced regularly, the dissemination is phase occurs in each iteration. The dissemination phase is made up of various processes: updating output systems; producing, managing and promoting dissemination products; and managing user support (including feedback from user

<sup>2</sup> [Fundamental Principles of Official Statistics](#)

satisfaction surveys). These processes are generally sequential but can also occur in parallel and can be iterative.

21.15 21.14 It is also important to recognise the collection phase. This is critical and relies on effective and relevant communication with suppliers, which will have a different focus than that needed for dissemination to users. This phase collects or gathers all necessary information using different collection modes (including extractions from statistical, administrative and other non-statistical registers and databases) before internal processes take place thereafter. The collection phase is broken down into various processes, from design and creation of the frame (e.g., questionnaire, definitions, notes, etc.) and sample selection to setting up and running the collection processes. The approaches and processes may differ for the different types of source data, for example, administrative data and business survey data.

21.15 The dissemination phase incorporates the release of the statistical products to users. It includes all activities associated with assembling and releasing a range of static and dynamic products via a range of channels. These activities support users to access and use the outputs released by the statistical organisation.

21.16 More detail on the supplier relationship is covered in **section D**.

## 2. Organisational structure and the media

21.17 The statistical systems of individual countries have a range of approaches when it comes to managing external communication functions. The placement of those functions within the organisational structure will have an impact on their effectiveness. Such~~The~~ placement should ensure that the communication of statistical data and the associated technological infrastructure receives a high level of attention and investment. Increased supply of data from non-official data producers means that there is an increasing need for the statistical organisations to improve communication in terms of quality, content, timeliness and channels used to reach its different users, in particular the media and policymakers, as well as harder-to-reach groups (for example, students, researchers, etc.).

21.18 The link between the economic statistics compiler and the communications team is key. This link will ensure the technical nuances and message(s) are addressed in a way the communications team can effectively communicate and draw out the important messages for the users in an understandable way. The effectiveness of this link can be enhanced through media training for the compilers as well as basic macroeconomic statistics training for the communications personnel.

21.19 It is recommended that a~~All~~ external communications are~~should be~~ supported by a close working~~via a solid~~ relationship with the media team, who tend to be the main distributors of statistics to the broader public. In this way, the information is available to all at the same time without privileged accesses. There may be a limited number of people with time limited pre-release access in a secure setting for specific reasons such as media outlets to prepare their headlines and briefing or to enable officials to prepare for the briefing of government ministers at release time. In this case, the time-limit needs to be defined in such a narrow way that the risk of external interference is minimised and the existence of any such arrangements should be made public by the statistical organisation.

21.20 The communications team is usually responsible for the relationship between the statistical producer and the media by organising and coordinating press conferences, interviews with experts, requests from journalists and other requirements such as handling media crisis. Other key aspects that will need to be covered include handling social media, website management, digital design and data visualisation.

21.21 In line with the above guidelines~~requirements~~, contact with the media, their professionals and representatives, should aim to:

- Promote an open relationship.
- Foster mutual professional respect.
- Meet the needs of media.
- Treat journalists as legitimate representatives of the public.
- Provide information as quickly and completely as possible, in a factual~~truthful~~ and responsible manner supported in line by with evidence~~statistical producer interests~~.

### 3. Principles and standards

- 21.22 Official statistics should be reliable, objective and relevant for decision making. An appropriate dissemination strategy can be developed in line with the *UN Fundamental Principles of Official Statistics*, whereby Principle 1 states that "...official statistics are to be compiled and made available on an impartial basis by official statistical agencies to honour the entitlement of citizens to public information." Principle 1 sets out a clear steer for dissemination. Therefore, statistical organisations should provide users with maximum access to official statistics in accordance with confidentiality guidelines.
- 21.23 To help establish good dissemination practices, there is a range of information ~~about~~and good practices already available. For example, the European Commission has maintained the European Statistics Code of Practice (revised 2017), which discusses dissemination practices. Similarly, many countries have likewise developed statistics codes of practice suitable for their purposes, and important to note, these codes serve both users and producers.
- 21.24 **Box 21.1** shows several publications developed by the [United Nations Economic Commission for Europe \(UNECE\)](#) providing guidance to statistical organisations to aid communication and dissemination of statistics. These were prepared within the framework of the UNECE Work Sessions on the Communication and Dissemination of Statistics.

#### Box 21.1 UNECE guidance to statistical organisations covering communication and dissemination

##### UNECE Guidance to statistical organisations

The target audience is wide but [the guidance is](#) intended as a practical tool to help managers, statisticians and media relations officers, in particular those in the process of developing communication and dissemination strategies, and to aid training for new staff. -The guides also recognise there will be different approaches as well as practical and cultural differences across countries. See: <https://unece.org/statistics/making-data-meaningful>

- Making Data Meaningful – Part 1 - A guide to writing stories about numbers
- Making Data Meaningful – Part 2 - A guide to presenting statistics
- Making Data Meaningful – Part 3 - A guide to communicating with the media
- Making Data Meaningful – Part 4 - A guide to statistical literacy
- Getting the Facts Right – A guide to presenting metadata (with examples on Millennium Development Goal Indicators)

### 4. Data Dissemination Standards

- 21.25 In 2001, seven institutions, namely the Bank ~~foref~~ International Settlements, the European Central Bank, Eurostat, IMF, OECD, United Nations and the World Bank launched the Statistical Data and Metadata eXchange (SDMX) initiative and agreed to act as sponsors in order to develop common dissemination standards for the exchange of statistical information between public bodies at national and international levels. The SDMX information model covers various elements: descriptor concepts; packaging structure; dimensions and attributes; keys; code lists; and data structure definitions. The data structure definition is key as it conveys the data classification scheme that specifies the set of concepts required to describe and identify the statistical data items. [Statistical compilers are encouraged to use SDMX in disseminating statistics to the international organisations which will improve comparability and ease of accessing data from across countries.](#)
- 21.26 Countries are also encouraged to subscribe to the IMF Special Data Dissemination Standard (SDDS or SDDS Plus) or the Enhanced General Data Dissemination System (e-GDDS) for those agreeing to basic standards. These data standard initiatives encourage member countries to improve data quality. The National Summary Data Page (NSDP) is a "data portal" for economies participating in SDDS Plus, SDDS and e-GDDS, allowing users to access data, view metadata or browse links to online datasets for all available categories for an economy. For economies participating in SDDS Plus and e-GDDS, the

NSDP enables automatic exchange and sharing of statistical data and metadata in SDMX. Similarly, under the G-20 data gaps initiatives, several templates have been developed for the G-20 members to report data for various recommendations, for example, templates on shadow banking and institutional sector accounts.

## 5. Release calendar

- 21.27 The availability of a release calendar in advance of publication is important for users. Knowing when the information is released and disseminated will inform user expectations and enable them to plan their activities accordingly. For example, they can schedule the preparation of topical analyses of data releases in advance of publication. The compilation and release schedule should be realistic for compilers, as users may become frustrated if statistical organisations do not meet previously announced release timings and, at the same time, useful for users.
- 21.28 The release calendar should be published at the beginning of each year, or at least well in advance of the release date, on the websites of the statistical producers responsible for dissemination. This will also help to promote transparency and provide evidence that there has been no political or other inappropriate interference in the production and dissemination of official statistics.

## 6. Data revision and revision policies

- 21.29 Revisions are an essential part of data compilation in macroeconomic statistics. They will typically reflect new or improved data sources and methodologies but can also address corrections of past errors. Revisions, or alternatively better expressed as updates or improvements, arise as a consequence of the trade-off between the timeliness of published data and their quality, in terms of accuracy and comprehensiveness. Statistical producers may often compile and disseminate provisional data that are then revised when new and more accurate source data become available. Attempting to avoid revisions by producing accurate but very delayed data would fail to meet users' needs for timely statistics. Regular communication with users well in advance of expected updates and improvements to published statistical data will develop better public understanding of why revisions occur and help to ameliorate negative reaction.
- 21.30 Countries are encouraged to develop a well-designed revision policy that is managed and coordinated with related statistical domains and is communicated to users well in advance. Such a policy should aim to enable users to understand revisions in a systematic manner. The absence of coordination and planning of revisions can be perceived as a quality problem by users. An essential feature of a good revision policy is a predetermined schedule. Other features should include: reasonable stability from year to year; openness; advance notice of reasons for the revisions (perhaps also with some indicative size of the revisions); easy access for users to sufficiently analyse long time series of revised data; and adequate documentation on revisions in statistical publications and databases. To help users better understand revisions, the analysis of revisions is considered useful and may be published.
- 21.31 In some cases, the compiling agency may decide to carry out a special revision for the purposes of reassessing the data coverage or data compilation methods, which could lead to significant changes in the historical time series. It is recommended that such revisions be announced in advance and accompanied by explanations the reasons for such revisions, along with an assessment of their possible impact on the available data, could be provided (see also the forthcoming United Nations Handbook on National Accounting Backcasting Methodology).
- 21.32 As part of the compilation and evaluation process, the published revisions should be evaluated to identify any persistent revisions to the earlier estimates of the aggregates or sub-aggregates in order to understand the potential for any systematic bias. This process will lead to identifying improvements to sources and methods thereby improving the quality of the future published estimates and reduce any revision bias.
- 21.33 Composition of revisions and explanations for users is covered in section F.

## C. Communication with users

- 21.34 Macroeconomic statistics should be designed to meet the needs of a wide variety of users making different uses of the statistics.

~~21.34~~21.35 An understanding of the possible user needs is vital in identifying effective ways to communicate statistical information. Knowing who the users are helps to guide the content of the message being conveyed when statistics are released in a language accessible to all. Also, the content and the form of communication needs to be adaptable in responding to rapidly changing user needs, for example, during periods of significant economic change and major economic events (e.g., COVID-19 pandemic).

~~21.35~~21.36 The user community includes a range of diverse groups such as government, business, academia, analysts, economists, researchers, journalists, international statistical agencies, the media and the public. For macroeconomic statistics, users can be grouped into two main categories. There are *general data users* (such as general journalists, students, teachers, small businesses or ordinary citizens) who have wide ranging but simple data requirements ~~but from a great range of information~~ and *analytical users* (such as government departments, local authorities, researchers, economic journalists, central banks and international organisations) with complex data requirements on detailed variables, time series and regional or institutional sector breakdowns.

~~21.36 — An understanding of the possible user needs is vital in identifying effective ways to disseminate the statistical information. Knowing who the users are helps to guide the content of the message being conveyed when statistics are released in a language accessible to users.~~

21.37 To meet the different demands, the ~~communication~~dissemination of macroeconomic statistics can take a variety of forms, for example:

- Scheduled regular statistical releases, typically made available on-line and sometimes also featured as press releases, will be suitable for the media and the general public users, who may be particularly focused on the main findings.
- Special topic-related publications or methodological-type papers may be prepared, including time series and detailed data, accompanied by metadata and, on occasion, a short economic analysis based on these indicators.
- Highly comprehensive detailed macroeconomic statistics are usually presented in the form of scheduled annual datasets (or yearbooks) and made available online.
- Social media posts or similar short forms of communication can be used to supplement formal statistical releases and highlight newsworthy features of the published data to broader audiences.

21.38 Good standards of data visualisation in the design of tables and charts can have a role in effective dissemination of statistics. There is also a role for independent users of statistical data to develop and maintain innovative or well-designed online data visualisations of official statistics. Statistical producers can encourage innovation of this kind by publishing appropriately extensive definitions and by making datasets available in technically compatible ways, for example, comma-on-separated value files.

~~21.39 — Statistical producers can also use online platforms like crowdsourcing which invite the public to share data and information as well as collect data which would be unavailable to data collectors through the usual channels. Other new channels that may be utilised include artificial intelligence providers.~~

~~21.40~~21.39 As indicated, it is important to be aware of the user base and for each user bases ~~but also~~ “what” should be communicated ~~to the user~~ and “how” it should be communicated. The relevance of what is being communicated needs to be clearly understood, and in turn, the most appropriate channel form of communication should be considered, for example:

- Data – estimates versus projections. As the release vintages evolve, it would be useful to convey information on the increasing data content, thereby reducing data uncertainty.
- Current data versus historical (or archived) data.
- Level of aggregation.
- Micro data versus macro data.
- Metadata.
- Story or knowledge adding explanations to understanding the data movements.

~~21.41~~21.40 In terms of the “how” considerations, there are different channels, for example:

- Printed format (for example, press releases, newsletters, infographics, etc.) versus electronic

(for example, [PDF documents](#), Excel files, infographics, XML, [downloadable datasets](#), etc.) or available in both forms.

- Different machine-readable formats that better suit users' needs.
- Internet release thereby addressing website design, search facilities, etc.
- Video releases, blogs, podcasts, presentations, live streaming, etc.
- Databases, tables charts, animations, etc.
- Social media.

~~21.42~~21.41 As different users use a range of different devices, for example, desktop, laptop, tablet or smart phones, statistical producers should seek to ensure that their release modes remain as widely accessible as possible, and not limit their approach to just one design of online format.

~~21.43~~21.42 Other aspects of statistical dissemination that may require consideration include:

- Freely available detail versus charged bespoke analyses requested by users.
- Regular analysis of press coverage and feedback to get early indication of changing user demands.
- User satisfaction surveys providing feedback to aid continuous improvement.
- Seminars, webinars, workshops and conferences involving different groups of users (and producers) to increase their awareness and sign-post developments.
- Providing training and education of macroeconomic statistics [for users](#).

## D. Communication with data suppliers

~~21.42~~21.43 Similar to the engagement between statistical producers and users, various initiatives and engagements between statistical producers and data suppliers are ~~crucial~~[needed](#). From the statistical producer perspective, there should be an effective data supplier engagement strategy as the suppliers have a significant stake in helping to produce high-quality official macroeconomic statistics. This strategy will need to reflect the different types of suppliers of information [and the different ways the information is supplied](#), for example, business surveys, administrative data, household surveys, etc. ~~as well as the different approaches used to collect these statistics.~~

~~21.45~~21.44 Historically, suppliers do not enjoy as high a profile as is the case with users, yet cooperation with the different data suppliers is crucial. Minimising the burden and communicating effectively are paramount to maintaining this cooperation as suppliers can feel 'there is nothing in it for them' when completing requests for information. Therefore, it is imperative that suppliers understand how important it is for them to supply their information and trust statistical producers to be fair and maintain the security of their data from the outset. There is an ever-increasing need to improve data suppliers' experience in completing the demands from statistical producers. The strategy should help suppliers understand why their participation is important. With respect to individual entities that serve as important suppliers of statistical data, for example, businesses, major corporations, banks, government departments, etc., statistics producers should promote cooperation by explaining the essential value of the required data; minimising the reporting burden as far as is reasonably practicable; assuring data suppliers that proper standards of security and confidentiality are applied; and acting on their feedback as appropriate.

~~21.46~~ There is an ever increasing need to improve data suppliers' experience in completing the demands from statistical producers. The strategy should help suppliers understand why their participation is important and what they can expect from the producers as well as the initiatives to reduce the statistical burden on suppliers. In particular, statistical producers should explain how they will keep suppliers' information secure and confidential, value their time by making it as easy as possible to contribute to the business survey questionnaires and improve communication with them, as well as listening and acting upon their feedback.

~~21.47~~21.45 Some key principles to reflect on:

- Providing choice to data suppliers (e.g., telephone data entry, secure electronic file transfer, etc. in addition to traditional paper submission) and recognising that their time is valuable.

- Minimising impact or burden on data suppliers (e.g., fair and equitable when it comes to how often they are selected in survey samples, only asking for the information once or minimising any duplication).
- Having high standards for how statistical producers communicate with **data suppliers/**~~respondents~~ (e.g., standardised responses, phone call assistance and data collection, timely communication).

~~21.48~~21.46 Producers of official statistics also need to consider the way they communicate with their data suppliers, who represent a unique set of stakeholders that may or may not be users of official statistics. In particular, the use of the concepts, terms and definitions~~language~~ that suppliers can understand is essential in collecting data to enable the compilation of statistics in line with the concepts, terms and definitions of the macroeconomic statistical standards, either directly or appropriately adjusted to meet the relevant definitions. ~~Interestingly, this “language” will differ in many respects from that used when communicating with users.~~

~~21.49~~21.47 Data collectors may not be able to use the language, terminology, etc. used within the macroeconomic statistical standards when communicating with data suppliers. Instead, they need to converse with data suppliers using company accounting or administrative terms and definitions. To enable this, for example, the questions and notes on survey questionnaires should be tested with a sample of **data suppliers/**~~respondents~~ or bridge tables may be needed to link the business survey data or administrative data to concepts and definitions needed to comply with those in the macroeconomic statistical standards. It is important to use common concepts, terminology and classifications when designing business survey questionnaires in a language the supplier will understand as well as applying similar principles when publishing business survey results to aid the users. Comparability is not possible~~Without some uniformity across the published business survey data, then comparability is not possible. In addition, along with published data, some companies may provide more detail than published in the format of financial statements or using bespoke survey questionnaires designed by the producer in conjunction with the company which will require appropriate conversion for macroeconomic statistical purposes.~~

~~21.50~~21.48 Often it is an accountant that responds to official statistical producers’ requests. They tend to be more familiar with business accounting concepts, terms and definitions~~language~~ than those with the language used in the macroeconomic statistical standards. ~~Building on the links between business accounting standards and macroeconomic statistical standards, the data supplied will then either be used directly or aggregated as necessary or be adjusted appropriately to meet the definitions required, to feed the macroeconomic statistics production process.~~ Data collectors also need to be aware of any changes to the business accounting rules, including changes to terminology, to ensure the data collected remain valid. Sometimes the accountant may not be able to provide all the data needed, for example, labour related information such as hours worked, numbers employed, etc. is supplied by the human resource (personnel) department. Here, it is important to ensure the information provided is consistent, for example, covering the same reference period.

21.49 Statistical producers can also use online platforms like crowdsourcing which invite the public to share data and information as well as collect data which would be unavailable to data collectors through the usual channels. Other new channels that may be utilised include artificial intelligence providers. However, given the novelty of these data sources, statistical producers would need to ensure that methodological and quality issues are appropriately addressed.

~~21.51~~21.50 Data collectors could provide feedback to data suppliers on the quality, including accuracy and reliability, of the data they provide. This feedback loop allows data suppliers to address any issues or errors in their data submissions and helps maintain, or improve, data quality standards. Other examples of effective communication to improve the supplier experience that could be considered include:

- A survey calendar that gives suppliers an indication of when they can expect to receive a questionnaire.
- Sharing of survey results to which they have contributed.
- Personalised statistical feedback, including sharing tables with suppliers where they can see their own contributions to the totals.

## E. Statistical confidentiality

21.51 In terms of statistical confidentiality, by law, most official statistics producers collect data from businesses, government bodies and households for statistical purposes only and mostly under some form of legislation. Statistics based on these data generally cannot be disseminated, sold, or published in a way that permits the identification of data referring to a particular business or household. Thus, it is important to ensure appropriate data confidentiality policies, anonymisation techniques and disclosure checking procedures are in place as part of the process before publication of any data. There is EU guidance covering the General Data Protection Regulation (GDPR) and the protection of microdata as well as the UNECE Statistical Disclosure Control Committee endorsed book, *Statistical Disclosure Control* (August 2012, Wiley).

21.52

21.53 21.52 One of the most important policy concerns relevant to data dissemination is the preservation of statistical confidentiality. Statistical confidentiality is necessary in order to gain and keep the trust of both data suppliers to statistical surveys and users of the statistical information. Principle 6 of the Fundamental Principles of Official Statistics stipulates that individual data collected by statistical agencies for statistical compilation, whether they refer to natural or legal persons, are to be strictly confidential and used exclusively for statistical purposes. It is therefore important that appropriate disclosure checking procedures are in place as part of the dissemination process. In any case, permissions need to be sought from a business to publish information that would otherwise be considered confidential so as to avoid the loss of fundamental pieces of statistical information. It is also important to clearly communicate confidentiality statements and arrangements to data suppliers and users. In some cases, confidential information may be provided to a specific, limited number of users under strict and agreed conditions for the purposes of validation and quality assurance before its official release. For example, where data validation by an external organisation or a specific expert is necessary or significant benefits as part of data quality assurance are expected or have been previously demonstrated. Such specific cases should be adequately publicised for transparency, for example on the website of the relevant producers.

21.54 21.53 As much as statistical confidentiality is very important, it should not be used in itself as a reason not to release information. Instead, the goal should be to maximise the dissemination of information as a public good for the wide range of users while still ensuring confidentiality obligations are met. It should be recognised that as more granular information is collected to meet increasing user demand for more detail, this may lead to more cases of disclosure and suppression or aggregation of cells.

21.55 21.54 On a global scale, there is a growing challenge to ensure the data covering multi-national enterprise (MNE) groups are properly and adequately covered (see also chapter 23). The various impacts of globalisation (e.g., cross-border flows like intellectual property products, impact of change in economic ownership, merchanting, etc.) imply that domestic only data collection is insufficient to ensure all activities of the MNE group are adequately captured and understood as well as to ensure a reduction of trade and financial account asymmetries to the extent possible. Respecting individual jurisdictions' rules on confidentiality, there is a need for statistical producers to be able to exchange data, share data and reconcile the activities of MNE groups. This requires setting up of appropriate legal agreements and utilising secure channels to enable data exchange. More details are provided in the *UNECE Guide to Sharing Economic Data in Official Statistics* (2021).

21.56 21.55 For researchers, alternative approaches allowing access to micro data for statistical ~~purposes~~ or research purposes should be considered, for example:

- Secure data labs to allow researchers to access and analyse micro data, whereby the research published does not reveal any confidential data.
- Signed data access agreements, which allow access to secure online data areas for specific research or analyses and with limited time.

## **F. Taxonomies and metadata**

21.57 21.56 When statistics producers publish macroeconomic statistics, they also need to provide information about the product and context of the released statistics in order to enable users to properly use and adequately interpret the data.

21.58 21.57 This section provides guidelines, including taxonomies, that statistical producers should consider integrating into their current communication practices as appropriate. These practices will assist users and, if standardised, help to improve cross-country comparability.

## 1. Metadata

[21.59](#)[21.58](#) Metadata may be understood as “data about data” that can enable and facilitate sharing, querying, understanding and using statistical data across process stages such as collection, compilation and dissemination. Metadata apply to data definitions at different levels of aggregation, from micro data to macro data. Accessible and comprehensive metadata also promotes data literacy by helping users navigate complex statistical concepts and understand the nuances of economic indicators. They encompass administrative facts about the data such as who created them and when, and the definition of the concepts applied along with a description of how the data were collected and processed before they were disseminated or stored in a database. Metadata are important for both producers and users. Common standards and definitions for metadata should be followed to the extent possible throughout all statistical domains, in order to facilitate the linking and integration of statistical information such as the examples covered in paragraphs 21.25 and 21.26.

[21.60](#)[21.59](#) Metadata dissemination should be an integral part of the dissemination strategy. As metadata are generated and processed during every step of the compilation process, there is a strong need for a metadata management system to ensure that the appropriate metadata retain their links with data. A good practice in this regard is the active linking of metadata to the statistical data that they describe, and vice versa, by implementing a system that allows metadata to be recorded as part of the data infrastructure throughout the various stages of the statistical production process.

## 2. Releases and vintages of data

[21.61](#)[21.60](#) National statistics producers have developed a range of practices for communicating statistical outputs, updates and methodological changes to users. These practices have greatly assisted with the interpretation and use of national accounts, external accounts and government finance statistics data as well as various other statistical domains. ~~This national approach to communication has been driven in part by limited guidance provided previously in macroeconomic statistical standards. This variation in nationally determined approaches reflects the historically limited available guidance in macroeconomic statistical standards.~~ For example, countries use phrases such as provisional, first, preliminary, second and final to communicate different vintages of economic statistics. Furthermore, the substance of a given release is communicated using terms such as initial estimates, mature estimates, final estimates, data revisions, benchmark revisions, rebased estimates, improvements to methods and corrections among others and experimental estimates.

[21.62](#)[21.61](#) Producers of macroeconomic statistics should match the need that users have for timely, high frequency economic data with their need for highly accurate economic data. In addition to balancing this timeliness / accuracy trade-off, producers also need to match the expectations that users have for a long consistent time-series with their desire for agile macroeconomic statistical standards that ensure an exhaustive measure of economic activity.

[21.63](#)[21.62](#) Vintages refer to the release of updated economic statistics for the same time period, resulting from the availability or processing of new data such as more detailed or benchmark data surveys as well as methodological improvements. As vintages evolve, they are a regular and anticipated part of the statistical production process. They should be consistently described and their release dates pre-announced in a release calendar. To illustrate this and the type of future releases, consider a national authority who releases [an estimate of GDP]/[current account data] for the first quarter of 2023, on May 30<sup>th</sup>, 2023. Between 2023 and 2030 several revised estimates may be made for the first quarter of 2023 as illustrated in the example below:

- June 30<sup>th</sup>, 2023      2023 Q1 may be revised due to more data becoming available [and seasonal adjustment].
- September 30<sup>th</sup>, 2025      2023 Q1 may be revised due to benchmarking to annual estimates [through supply and use tables as well as revised seasonal adjustment analyses].
- May ~~29~~30<sup>th</sup>, 2026      2023 Q1 may be revised due to the results of an [economic census] /[benchmark survey].
- September 30<sup>th</sup>, 2030      2023 Q1 may be revised due to the implementation of the new international standards for macroeconomic statistics ~~[SNA]/[BPM]~~.

21.6421.63 Adherence to standardised definitions to describe different vintages of macroeconomic statistics will improve the use and interpretation of economic data. As well as the title and definition of the data release, the user needs to know the reference period to which it relates, the date of the release, the origin and quality of the sources. Consistent presentation standards can facilitate data comparisons between countries.

21.6521.64 Statistical producers should adopt the proposed common approach when communicating different releases or vintages of data to users. The description of the release, at a minimum, should include information about the: (1) substance of the release; (2) timeliness; (3) frequency; (4) the reference period; and (5) the update period. Defining, describing and communicating vintages of data is a complex undertaking. Before outlining this recommendation in detail, it is important to first establish a set of terms and definitions that help frame the recommendation as shown in **Box 21.2**.

### Box 21.2 Terms and definitions related to different vintages of economic data releases

- A **data point-item** is a discrete unit that can be represented numerically. There are different sources such as data collected, measurement of data based on data collected and model-based estimates.
- A **time series** is a series of regular time-ordered data values of a quantitative characteristic of an individual or collective phenomenon taken at successive, in most cases equidistant, periods / points of time.
- A **data vintage** is a data value or a dataset (sequence of values) for a given reference period that has been released for use at a particular point in time (release period). A new vintage of data is established when the same set of data for the same reference period or some overlapping portion of the reference period is released for use at a different point in time (release period).
- A **reference period** is the time-period represented by the data.
- The **update period** is the time-period over which revisions to a data value have been applied.
- A **release period** represents the calendar date when the data are released to the public.
- An **update** is a revision which is defined as the numerical difference between two vintages of the same data point.
- A **regular (or routine)**<sup>3</sup> **update** relates to the incorporation of scheduled, more complete (not necessarily final) source data, improved models, or other iterations of the compilation process. Regular revisions occur for both sub-annual and annual estimates and can occur throughout the year, at regular (often yearly or quarterly) intervals, or as new information becomes available. Regular revisions may also include for example, the impact of seasonal adjustment, the correction of compilation errors or minor methodological adjustments made outside the benchmark or comprehensive revision process.
- A **benchmark estimate** is the final vintage of a dataset, whereby there is no further expected improvement. It is compiled using the most comprehensive and highest quality source data and the most advanced methods at that point in time. Benchmark estimates are not expected to be further revised and therefore are often referred to as the “final” estimate. However, a change in the definition of the concepts used or the application of new macroeconomic statistical standard or the use of a new data source can change a benchmark estimate.
- A **benchmark update** reflects revisions from the incorporation of a benchmark estimate(s) into a given set of macroeconomic statistics or accounts.
- A **comprehensive update** is a special case of benchmark update where the revision to the macroeconomic dataset not only incorporates the final vintages of source data but also integrates new or updated concepts, the application of new accounting treatments, classifications or substantially improved methods or updating a base year. These generally occur when there are major changes to the macroeconomic statistical standards that are used to compile the accounts. These types of revisions often result in a discontinuity in the time series and a need for compilers to consider whether to apply methods such as back-casting to adjust historical data.

21.6621.65 Together the terms, routine updates, benchmark updates, comprehensive updates are the recommended terms to be used when communicating the “extent” or “substance” of revisions. The first two terms mainly reflect the vintage of source data that enter the compilation process. The term comprehensive revision reflects the addition or changes to concepts, methods (substantial changes),

<sup>3</sup> A regular / routine update can be referred to as either regular or routine with the same meaning and used interchangeably – we will use routine hereafter.

classifications or presentations. All other terms should be phased out as part of the 2025 SNA implementation.

**[The rest of this sub-section may will not be included in BPM7]**

21.6721.66 To illustrate the standard format recommended for communicating the notion of “substance”, series, reference period, timeliness, frequency, type of revision and update period to users, consider the following example. Assume that on average the first, second and third vintages of quarterly GDP are published 30, 60 and 90 days after the reference period, respectively. Assume further that the estimates are based on incomplete source data (such that each vintage is a result of a routine revision). These vintages could be categorised as shown in **Table 21.1**.

**Table 21.1 Naming Convention - Quarterly GDP (successive vintages for the same reference period)**

Series	Reference Period	Timeliness	Frequency	Type of Update	Update Period
GDP	First quarter, Year t	30-day	Quarterly		
GDP	First quarter, Year t	60-day	Quarterly	Routine	Year t, Q1
GDP	First quarter, Year t	90-day	Quarterly	Routine	Year t, Q1

21.6821.67 These vintages should be communicated as:

- Quarterly National Accounts release, first quarter Year t - 30-day
- Quarterly National Accounts release, first quarter Year t - Routine update – 60-day - (Year t-2 Q1 revised)
- Quarterly National Accounts release, first quarter Year t - Routine update – 90-day - (Year t-2 Q1 revised)

21.6921.68 For users’ reference, in line with the releases above, the vintages could be recorded using the real-time releases with the information as shown in **Table 21.2** where it can be seen by you see how the estimate for each period changes or not in successive releases.

**Table 21.2 Recording Vintages of Data in Real-time Tables: Quarterly GDP**

Series	Frequency	Release Date	Type of update	Q1 2024 1	Q4 2023 0	Q3 2023 0	Q2 2023 0	Q1 2023 0
GDP	Quarterly	June 30 <sup>th</sup> , Year t	Routine	99	95	90	85	80
GDP	Quarterly	May 30 <sup>th</sup> , Year t	Routine	102	95	90	85	80
GDP	Quarterly	April 30 <sup>th</sup> , Year t	Routine	100	95	90	85	80

Note, the above numbers are for illustrative purposes only.

### 3. Sources of product updates or revisions

21.7021.69 The macroeconomic statistical standards have three basic features. Firstly, they define the concepts to be measured. Secondly, they outline the methods that can be used to “quantify” those concepts and the accounting rules that need to be followed when recording various flows and stocks. Thirdly, they identify the classification systems, accounts, and table structures that should be used to present the data. One or more of these features can be the source of revising datasets or the presentation of datasets.

21.7121.70 Statistical producers should consider categorising and decomposing the source of the updates (revisions) into different categories reflecting the source of the revisions. These can include for example:

- **Conceptual changes** will cover alignment to an updated set of macroeconomic statistical

standards.

- **Methodological changes** will encompass for example:
  - coverage adjustments (for example, exhaustiveness);
  - changes to source data (for example, new results based on improved methodology for grossing of survey results~~response rates~~, replacing modelling algorithm with a survey-based estimate etc.);
  - quality improvements (for example, data validation, consistency of source data results, seasonal adjustment, etc.); and
  - accounting rules to be followed (for example, changes from cash to accrual accounting).
- **Presentational changes** will cover new tables, charts, revisions triangles, granular detail, etc. The aggregate(s) may not change but the way in which the components are presented are changed.

21.7221.71 Such a decomposition should depend on the source and size of the revisions and may be broken down further, if appropriate, for example, if a single revision combines multiple issues or affects multiple accounts, in order to help users' interpretation. Levels and growth rates effects of revisions should be distinguished. Producers may also wish to consider showing all the components of the revision(s) for a single period or across all periods revised.

#### 4. Types of statistical products

21.7321.72 Statistics producers seek to disseminate~~produce~~ established formats and content choices in statistical releases. They also seek to develop new releases or indicators in response to meeting changing user or public priorities or as new data collection projects come on stream. These can include developmental versions of statistical products, sometimes termed experimental statistics (or similar labels) that may not be of the quality required or data assured as existing products.

21.7421.73 Whatever the descriptor, the common theme is to communicate issues of quality such as whether the:

- estimates comply with nationally or internationally adopted conceptual and methodological standards;
- source data used to compile the estimates are ~~have been~~ reliably defined and produced; and
- compiling agency is producing the statistics in an exploration or in a development phase or is otherwise expecting user feedback on the data.

21.7521.74 It would be helpful for users if a consistent taxonomy could be adopted and applied through time and across countries to communicate the quality of the data. It is recommended that a two-level~~tier~~ taxonomy for classifying product quality be adopted as shown in **Box 21.3**.

**Box 21.3: Statistical product quality: Two-Level Taxonomy**

Level 1	<b>Official Statistics:</b> Estimates that incorporate recommended nationally or internationally adopted concepts, methods, accounting rules and classifications and meet all the standards required.
	<b>Official Provisional Estimates:</b> Provisional estimates incorporate nationally or internationally adopted concepts, methods, accounting rules and classifications but represent an early estimate before more comprehensive data becomes available.
Level 2	<b>Experimental Estimates:</b> Experimental estimates released by a statistical producer relate to statistical products that vary in limited ways from nationally or internationally recommended concepts, methods, accounting rules or classifications in the production of the estimates but where the producer has good confidence in their validity.

21.7621.75 The first level of official statistics will include official statistics and official provisional estimates. A key distinguishing feature of provisional estimates is that there is an expectation these early estimates will soon “graduate” to a revised, more mature official statistics status as the methods already meet the standard required. Statistical producers may compile and disseminate provisional data a number of days after the period in question or when a target data content has been achieved. The provisional estimate will mature to the full official estimate once new or more accurate source data become available. It is also possible within the same vintage of release that some data items might be “official” and others “official provisional”, for example, the observations for the latest period.

21.7721.76 The second level reflects experimental estimates released by a statistical producer. Often, they may be of a research or indicative nature or based on a range of modelling assumptions. The source data used to compile the estimates may be untested and its quality may not be quantifiable as would be the case with Level 1 official statistics or may be based on indicators / proxies which may not conform to the concepts required. The data are communicated with a “proof of concept” notion and the main motivation for releasing them is to seek feedback so the estimates can be improved upon. However, with a range of improvements to meet Level 1, they may meet the standard to be deemed as an official statistic. These releases tend to be more ad hoc with respect to frequency of updates.

**[the following six paragraphs will rest of this sub-section may not be included in BPM7]**

21.7821.77 In addition to the need to communicate the quality of a product to users there is also a need to situate the product within the overall framework. **Box 21.4** shows the taxonomy of the different accounts / tables and their relative placement.

**Box 21.4 Taxonomy of the different accounts / tables and their relative placement in relation to the SNA**

Economic Accounts / Tables	Placement
<b>Sequence of Economic Accounts</b>	Form the core accounts / tables underpinning the main sequence of economic accounts operating within the SNA boundary.
<b>Supplementary</b> Accounts / Tables (e.g., extended SUTs, IOTs, pensions, regional, environmental)	Operate within the SNA boundary and provide additional information that supplement the main sequence of economic accounts.
<b>Thematic</b> Accounts / Tables (e.g., health, tourism, sport, creative sector, etc.)	Operate within the SNA boundary and provide additional detail on a certain aspect or theme.
<b>Extended</b> Accounts / Tables (e.g., unpaid household work)	Operate beyond the SNA boundary and provide additional information beyond the sequence of economic accounts.

21.7921.78 The SNA is a framework covering a set of inter-related accounts that trace economic activity from production to distribution of income, expenditure, saving, capital formation, financing, revaluation and other changes affecting stocks, to balance sheets representing stocks of assets and liabilities. In addition to a “prescribed” list of accounts and tables (i.e., sequence of economic accounts and supply and use tables), the SNA also recommends that countries produce additional information in the form of supplementary accounts / tables, extended accounts / tables and thematic accounts / tables, etc. - all of which have a status different from that of the main sequence of economic accounts and briefly shown in **Box 21.4**.

21.8021.79 Users would benefit if statistical producers followed similar practices and common definitions when referencing the products or statistical outputs associated with a particular statistical standard. Here, users will better understand how the different accounts fit together and how they compare across countries. In addition to defining an account, there is also a need to delineate between those accounts that are part of the sequence of economic accounts and those outside the sequence of economic accounts.

~~21.81~~21.80 Accounts as defined by the SNA have an opening and closing item linking resource and use flows (related to a certain group of transactions and other flows) and stocks (levels). Accounts are also related to each other such that the closing balance of one account can be the opening balance of the subsequent account. The term “table” is distinguished from account in that tables do not have a balancing item and are not part of the sequence of economic accounts. Specific tables tend to be extracts from an account or several accounts and illuminate particular aspects.

~~21.82~~21.81 The macroeconomic statistical standards also offer the flexibility to develop thematic accounts / tables. These types of accounts / tables are covered in more detail in chapter 38 on thematic accounts and provide statistical producers the opportunity to experiment with both the classification, concepts and presentation to provide a fuller, more detailed picture of the activities involved.

21.82 The macroeconomic statistical standards also include recommendations related to the development and dissemination of supplementary tables such as those covering pension entitlements or extended tables like unpaid household activities.

### [the following two paragraphs will not be included in the 2025 SNA]

21.83 This *Manual* shows a standard presentation, which is designed to be used flexibly and to support many kinds of analysis. However, it is recognized that no single framework can meet all the different analytical interests. Thus, thematic, extended, and other supplementary accounts presentations are encouraged (see also Chapter 21 of the *2025 SNA*) for thematic, extended and other supplementary accounts. Such presentations would be based on the circumstances in each economy and are not included in the standard components or memorandum items. They may include data from other sources that are not necessarily obtained from the external accounts compilation system.

~~21.83~~21.84 Thematic, extended, and other Supplementary accounts presentations provide a framework linked to the central accounts standard presentation and that enable attention to be focused on a certain field or aspect of economic and social life international presentation external linkages. Common examples for the national accounts include the environment, tourism, and nonprofit institutions. Examples include trade and investment income by enterprises characteristics; trade by currency; separate identification of factoryless goods production; direct investment by ultimate investing economy; by ultimate host economy; etc., which are developed in the context of globalization. In addition, the external accounts have more detailed presentations for direct investment, portfolio investment, external debt, remittances, tourism, and reserves. The analytic and monetary presentations are discussed in Chapter 19. Statistics on activities of multinational enterprises (as discussed in Chapter 15) are also a related data set. These presentations use the basic framework as a starting point but differ by adding detail or other information, or by rearranging information, to meet particular needs. Use of the basic framework as a starting point increases the ability to relate the topic to other aspects of the economy while maintaining international comparability. Specific manuals and guides are produced on some of these topics. The range of supplementary data is wide and can be developed according to national circumstances.

## 5. Presenting the tables and accounts

### **This sub-section may will not be included in BPM7**

~~21.84~~21.85 The SNA provides the main sequence of economic accounts and tables, broken down by institutional sector(s) as well as the rest of the world. The full set of transactions, other flows and stocks are broken down into the different accounts from the production account through to the balance sheets. To avoid over-crowding the main accounts / tables, in each of these accounts / tables there may be further breakdowns, for example by institutional sector, by industry, by product, by function, by transaction, by flow, by stock, by asset, by liability, etc.

~~21.85~~21.86 In the SNA, specific unique codes are shown where applicable as covered in Annex II, for example, S – institutional sectors and sub-sectors, B - balancing items, P - products, D - distributive transactions, F – financial transactions, etc. Specific suffixes are reflected in the rest of the world accounts functional categories, for example, D - direct investment, P - portfolio investment, F – financial derivatives, etc. Each of these categories may have different levels or types of further breakdowns, some of which are covered below.

~~21.86~~21.87 To aid cross-country comparisons and to aid the user, statistical producers should “publish” a range of other breakdowns using the agreed international classifications and their respective hierarchies

within those classification. For example:

- In terms of the industry breakdowns. For example, the production and income approaches to measuring GDP, gross fixed capital formation, changes in inventories and labour can all be split by industry using the International Standard Industrial Classification (ISIC) Revision 5. The ISIC Revision 5 splits the economy by industry at the section level (one letter codes, for example, A – agriculture, forestry and fishing, B – Mining and quarrying, etc.). These sections are further split into divisions using two-digit numeric codes, for example, separating out 01 - agriculture, 02 - forestry and 03 - fishing. These divisions can then be further split into groups, and in turn further split out into classes. Countries can, and do, have greater level of detail depending upon the activity in the economy.
- In terms of a functional link. Household final consumption expenditure is typically published as a whole economy aggregate but can also be published using the two-digit categories known as Divisions of the Classification of Individual Consumption According to Purpose (COICOP) 2018. For example, 01 Food and non-alcoholic beverages, 02 Alcoholic beverages, tobacco and narcotics, etc. More detail can be published for each of the two-digit COICOP divisions, split further into groups, in turn split further into classes.

21.8721.88 Examples of other additional tables which are useful for a range of users providing variations supporting an aggregate, for example:

- GVA can be presented by institutional sector, by market and non-market sectors, and by public and private sectors.
- Household final consumption expenditure can be shown split by type of goods characterised by durability (non-durable, semi-durable and durable), services and the link between the national and domestic concepts (i.e., resident's expenditure abroad and non-resident expenditure within the economic territory).
- Gross fixed capital formation and changes in inventories can be analysed by industry or by institutional sector or by type of asset.

21.8821.89 Countries' own classifications may have a greater level of detail and will depend upon the scale or uniqueness of the activity in the economy, resources available for data collection and user needs. Nonetheless, these national classifications for publication and dissemination should preferably align either one-to-one or many-to-one to the international classifications.

21.8921.90 The data collection, compilation or balancing may take place at different levels reflecting, for example, the diversity of the economic activity and resources available to the statistical producer. However, allowing for statistical disclosure, the publication levels should reflect the international classifications. For example, if the ISIC is used as described in **paragraph 21.85**, this would enhance the quality of labour and capital productivity analyses within an economy as well as international comparisons. Also, the use of the correspondence tables linking the different classifications enhances the user linking and analytical capability.

21.9021.91 For further details, see **2025 SNA, Annex 2**, Classification and Coding Structure of Accounting Entries which also shows references to other international classifications that may be used. **[to be cross-checked when complete]**

## **G. A framework for measuring alignment with the international macroeconomic statistical standards**

21.9121.92 An important feature of the macroeconomic statistical standards is their ability to develop internationally consistent macroeconomic statistics which in turn facilitate the comparison of estimates across countries. However, when countries use a macroeconomic statistical standard to compile macroeconomic statistics, they have ~~some~~ discretion in implementing the recommendations to accommodate their specific circumstances while maintaining comparability and quality to the extent possible. ~~These circumstances could range~~ For example, ranging from limited resources and data availability to systems constraints to user needs and meeting policy demands. For pragmatic and resourcing reasons, the macroeconomic statistical standard recommendation may not be implemented, if an activity or concept is economically immaterial for a given economy. This results in varying degrees of 'alignment' to these standards across countries. For users to be confident when making cross-country

comparisons, they need some assurance that the economies' estimates are compiled on the same basis.

21.9221.93 A set of internationally accepted alignment frameworks (e.g., for the SNA, BPM and GFS) have been developed to provide structured, systematic and consistent methods to assess an economy's alignment to these standards. These alignment frameworks draw heavily on existing assessment frameworks and tools available to users. For example, the IMF's Data Quality Assessment Framework (DQAF) and Reports on the Observance of Standards and Codes (ROSCs), the UN's Data Quality Assessment Framework (UN-NAQ), and the ISWGNA's Minimum Required Data Set (MRDS).

21.9321.94 The alignment frameworks are stand-alone tools intended for national statistical authorities and international agencies to assess macroeconomic statistical methodologies and processes at country or country-group levels.

21.9421.95 These alignment frameworks are voluntary and based on self-assessment. They allow countries periodically to assess their macroeconomic statistics and development programs. It is important for statistical producers to maintain transparency and document any deviations or adaptations from the macroeconomic statistical standards in their metadata and methodological notes. Thus, they are encouraged to use these common frameworks and make the results publicly available in accessible ways for all users. This section focuses on the alignment framework for the [SNA]/[BPM] domain. The alignment framework is structured around the key building blocks of the statistical standards – concepts and definitions, methods, classifications and the resulting accounts tables that are produced and published.

## 1. Alignment framework for the [2025 SNA]/[BPM7]

21.9521.96 The [2025 SNA]/[BPM7] alignment framework described below reflects a degree of flexibility and is considered after the initial set-up investment, to be and is relatively easy to implement, update and communicate after an initial set-up investment. It is structured around four key high-level components:

- **Concepts and definitions** – reflect the articulation of a macroeconomic activity, interaction, state or ideas. Concepts describe what gets measured.
- **Methods** – describe how a compiler implements an accounting rule or measures a concept.
- **Classifications**– determine the level of detail and its conformity or otherwise with the 2025 SNA / BPM7 classification schemes used by compilers and presented to users, for example, by industry, product, region, or functional categories or instruments.
- **Accounts / tables** – outline how information is presented to users. The SNA and BPM have a set of accounts or tables that form the basis of the respective standards, which in turn have been used as the basis of the structure of the alignment frameworks.

21.97 These four categories serve as an overarching structure for the alignment frameworks. Given the SNA and BPM have many concepts and definitions, accounting rules, methods, classifications and accounts / tables, to be pragmatic only a subset is expected, in the sense that the individual items to be included in the framework focus on those categories that impact the interpretation and assessment of levels and growth rates. Using these criteria, a brief overview of the [2025 SNA]/[BPM7] alignment framework with a few example questions is shown in **Table 21.6** (with fuller detail available in the [LINK](#)). Consistent and similar detailed lists have been developed for the [BPM]/[SNA] and future GFSM update. The proposed levels and the categories of alignment provide flexibilities to help economies share details based on the level of development of their national statistical system.

21.9621.98 It is worth noting that, the B balance of pPayments data and SNA Rest of World data may need to be reconciled given there could be two potential data sources presenting essentially the same information from two different perspectives. Where reconciliation is not made, differences will exist and these would need to be explained.

**Table 21.6a Overview of the SNA Alignment Framework with a few examples of the questions [this version for inclusion in the 2025 SNA]**

Classification of financial assets and liabilities by instrument			
Classification of services			

#### Accounts / Tables

Category	Timeliness (e.g., T+30 days, T+3 months, etc.)	Granularity (level of detail)	Limitations (e.g., any missing lines)
BOP standard components and memorandum items			
IIP standard components and memorandum items			
Other flows standard components and memorandum items			
Reserve-related liabilities			
Non-performing loans separately at fair value			
Currency composition of assets and liabilities and institutional sector			

## 2. Benefits to users and producers

21.9721.99 At any given time, it is likely that different countries may be conforming to different editions of the macroeconomic statistical standards or with varying extents of implementation, for example, 1993 SNA or 2008 SNA or 2025 SNA and BPM5 or BPM6 or BPM7. As a result, cross-country data may not be directly comparable because of variations in aspects of the underlying concepts, methodologies and coverage of the data by the different economies. The proposed alignment framework provides a structure for users to assess national statistical practices in a comparable way.

21.9821.100 The alignment frameworks **bringprovide** several key benefits for national users and the international community. The degree of alignment with the macroeconomic statistical standards provides important signals to users about the quality of cross-country comparisons and the extent to which major revisions should be expected in the future, in cases where an economy is not aligned with the latest macroeconomic statistical standards. The alignment frameworks also provide a mechanism to present and communicate this information to users in a standardised manner.

21.9921.101 The **proposed** alignment framework would assist users in making cross-country comparisons. To illustrate, consider two countries A and B. Country A indicates it uses the 2025 SNA to compile its national accounts and BPM7 for its balance of payments but does not record some of the smuggling activity, neither the stocks nor the flows. Country B also uses the 2025 SNA and BPM7 and records smuggling activity in its national accounts and balance of payments. When comparing the data on gross value added, balance sheets, productivity and the cross-border flows of the two countries, it is important for the user to understand these differences. Country A may not record smuggling because these activities **are it is** not material for that economy or it may be material but the compilers may have no data. If it is not material, then Country A should be encouraged to provide this information to users so that they do not attempt to compensate for the different treatment when making the cross-country comparisons.

21.10021.102 The alignment information also benefits producers of statistics to identify areas for improvement, prioritise resources and formulate strategic plans to align better to the macroeconomic statistical standards as well as assist users to make appropriate adjustments to achieve comparability in their analyses, among others. In addition, this type of detail will help to **giveprovide** users assurance **as regards-of** the statistics and increase their capacity to provide feedback on future priorities and demands.

21.10421.103 It should be noted that the alignment frameworks do not **provideoffer** a comprehensive evaluation of the quality of an economy's macroeconomic statistics as this would require a more rigorous, and different, type of investigation. It will be expected that the design and application of alignment frameworks will evolve over time.

## 3. Communicating the alignment framework with users

~~21.102~~21.104 Having established and completed the alignment framework, it is important how compilers communicate this information to users to ensure it is understood and used appropriately. It should not be used as a form of a scoreboard due to the various flaws in establishing a highly subjective weighting system (e.g., aligning to concepts is, or is not, more important than aligning to accounting rules). Instead, it is recommended that a dashboard approach is taken. Such an approach does not attempt to quantify or summarise the information but will still provide useful information to users in a simple, straightforward and flexible manner.

~~21.103~~21.105 Many of the items in the alignment framework can be structured to provide a “yes” or “no” response, however this may not ~~deliver~~<sup>provide</sup> the granularity needed by users to properly interpret the results. As the framework is intended to measure the degree of alignment to a standard, it is better to show the notion of “degree” of alignment, for example, for each question or group of questions, the compiler can indicate whether the country is:

- **Fully aligned** with the standard – meaning that between 95-100 per cent of the guidelines and standards are implemented.
- **Highly aligned** with the standard – meaning that between 75-95 per cent of the guidelines and standards are implemented.
- **Broadly aligned** with the standard– meaning that between 50-75 per cent of the guidelines and standards are implemented.
- **Partially aligned** with the standard – meaning that between 25-50 per cent of the guidelines and standards are implemented.
- **Not aligned** with the standard – meaning between 0-25 per cent of the guidelines and standards are implemented.
- **Not applicable** – meaning that for issues of materiality or relevance, the standard is not implemented. Materiality in this context is subjective but a steer would be less than 0.05 per cent (and/or a monetary equivalent) of GDP.

~~21.104~~21.106 The introduction of the notion of “per cent aligned” does introduce some subjectivity and flexibility into the exercise, thus a range approach is adopted as it is difficult to define (and impossible to measure) what would constitute being 100 per cent aligned to a concept, accounting rule, method, etc.

~~21.105~~21.107 The fully aligned, partially aligned and not aligned categories are appropriate when considering concepts and definitions, methods, and accounting rules but not when considering classifications used, tables or accounts. It is proposed that the timeliness (days released after the reference period) and granularity (number of detailed classes) be used in “quantifying” the alignment of tables and accounts to a given standard.

~~21.106~~21.108 It is recommended that the dashboard be presented in digital format and included as a part of the sources and methods documentation for a given macroeconomic statistical standard. The assessment can be done for the entirety of a macroeconomic statistics or it can be completed for individual accounts or tables. It is also recommended that the assessment be colour coded, which avoids spurious precision and allows easy to understand and quick messages to be conveyed such that:

- Fully aligned = Green
- Highly aligned = Light green
- Broadly aligned = Yellow
- Partially aligned = Light yellow
- Not aligned = Red
- Not applicable = Black

## H. Prominence given to indicators other than GDP and the clarification of the use of the term “net”

**This sub-section will not be included in BPM7**

~~21.107~~21.109 The role and prominent use of GDP and other gross measures has been well established in the

SNA sequence of economic accounts. However, the role and prominence of other indicators as well as net measures in macroeconomic statistics has increased significantly in recent years as users demand an enhanced set of national accounts that better support well-being and sustainability analysis. For example, net domestic product (NDP), net national income (NNI), household disposable income, consumption, saving and net worth, whereby measures of household income and wealth may be disaggregated by type of household and other characteristics, are already available. As signified in **chapter 2**, in some respects, the net measures are more important than the gross counterparts for capturing (environmental) sustainability considerations. Net measures are conceptually preferred as they are more reflective of the actual costs borne in production. However, the measurement challenges make it more difficult to arrive at comparable aggregates across countries.

21.10821.110 Thus, the importance of placing a greater emphasis on net measures and the indicators named above should be reflected in the outputs of the statistical offices. For example, net measures could be presented alongside the gross measures, not replacing but supplementing the gross measures. However, for the purpose of putting greater emphasis on net measures, it is needed to further improve their quality and timeliness.

21.10921.111 The 2025 SNA reflects an improved articulation of the differences in the concepts of depreciation (related to produced assets) and the notion of depletion (mainly related to non-produced assets, particularly natural resources). In the 2025 SNA, both are treated as the costs of production. Thereby the conceptual advantage of using ~~n~~Net measures such as NDP and NNI becomes clearer, requiring greater emphasis than previously needed, although users may still be interested in the gross counterparts.

21.11021.112 There are now two components of the gross to net adjustment, for example, from GDP to NDP, i.e., depreciation and depletion. This is a significant change for users to be made fully aware by the way in which the tables are presented. An example to show the distinctions is given in **Table 21.7**. Showing estimates of both components allows users the flexibility to use either version to meet their specific needs.

**Table 21.7 Moving from Gross Domestic Product to Net Domestic Product**

Transaction / Balancing item	Code	SNA data set
Gross Domestic Product	B1g	1 854
Depreciation (–)	P51c <i>(code to be confirmed)</i>	222
Depletion (–)	<del>K24</del> P51d <i>(code to be confirmed)</i>	14
Net Domestic Product	B1g <del>n</del> –P51c <del>–</del> <del>K24</del> P51d	1 618

21.11121.113 There is also a need to clarify the use of the terms net and gross for both producers and users to avoid confusion. Statistical producers should only use the terms net and gross in the following two areas:

- Firstly, in conjunction with the balancing items for each account by institutional sector and the whole economy, where the difference is due to the costs of depreciation and the costs of depletion.
- Secondly, there are two concepts where the net term is used in financial accounts: (i) aggregating acquisitions less disposals for each financial instrument on the asset side and on the liability side; (ii) aggregating changes in assets and changes in liabilities and showing both on a net basis. Further details covered in **paragraphs 4.268–4.276** (*[to confirm]*).

21.11221.114 All other uses of the term net tend to be legacies that need to be removed or act as a short-hand description, for example, net exports should be replaced with exports less imports. This has been reflected with the removal of the word net in the examples shown in **Table 21.9**. These and other such terms should be expressed in full to avoid any user confusion or misinterpretation.

## I. Use of more easier-to-understandable terminology for users

21.11321.115 The presentation of macroeconomic statistics can have a significant impact on how the statistics are interpreted and used. The macroeconomic statistical standards depend on an extensive use of technically precise terminology and specialised constructs that may not be widely understood outside of the domain of economic statistics. Indeed, there may be situations where current terminologies are used inconsistently even within macroeconomic statistics.

21.11421.116 Therefore, macroeconomic statistics should be presented and communicated in such a way that the full extent of their analytical usefulness, quality, scope, comparability and policy applications is maximised and reflects the wide user base. To this end, the terminology and branding of the macroeconomic frameworks need an international communication strategy that aligns with the latest technology and current cultural norms.

21.11521.117 The macroeconomic statistical standards have lots of similar technical descriptions of concepts and underlying definitions with explicit inclusions and exclusions. The commonality of the labels and concepts help the producers and facilitate communication across the producers' community. However, they are often not user friendly or understood by users, and it is important that statistical producers target their communication.

21.11621.118 To improve the consistency, readability and understandability for non-specialists, a new feature of the 2025 SNA and BPM7 has been the development of a common glossary of terms and definitions used in macroeconomic statistics. This glossary reflects input from across several existing standards and manuals: SNA; BPM; European System of Accounts (ESA); Government Finance Statistics (GFS); Monetary and Financial Statistics (MFS); System of Environmental-Economic Accounting (SEEA); International Public Sector Accounting Standards (IPSAS); and guidance from the Bank for International Settlements (BIS). This glossary thus delivers a further level of harmonisation across macroeconomic statistical standards and provides users with a clearer and more consistent understanding of key economic terms and definitions together with some alternative easier to understand terms. **(link to be inserted when available)**

### 1. Other changes reflected within the **[2025 SNA]/[BPM7]** This section is likely to appear in one of the Annexes to the 2025 SNA and BPM7 and not in this chapter as appropriate

21.11721.119 Significant steps have been made to harmonise the concepts and methodologies in the macroeconomic statistical standards, in particular within the body of the 2025 SNA and BPM7 without changing the technical definition(s). This effort has also reflected a new Common Glossary of macroeconomic statistics, the alignment of terminologies (affecting variables, account labels, etc.) and improved the branding of the statistical standards such that comprehension and usability of macroeconomic statistics has been improved.

21.11821.120 Examples of other changes agreed affecting the names of the **[SNA]/[BPM]** accounts are shown in **Table 21.8**.

**Table 21.8a** Changes to the Names of the SNA Accounts

2008 SNA Terminology	2025 SNA Terminology (Individual economic account)	Economic Accounts Groups
The production account	No change	Income and Expenditure Accounts
The generation of income account	The generation of earned income account	
The allocation of primary income account	The allocation of earned income account	

<b>2008 SNA Terminology</b>	<b>2025 SNA Terminology (Individual economic account)</b>	<b>Economic Accounts Groups</b>
The secondary distribution of income account	Transfer income account	Accumulation of Economic Assets Accounts
The use of income account	No change	
The capital account	No change	
The financial account	No change	
Other changes in assets account	Other changes in assets and liabilities account	
Balance sheets	No change	Balance Sheets

(needs to be cross-checked / amended against final Editorial Team agreement on Glossary Issue Note discussions)

**Table 21.8b Changes to the Names of the BPM Accounts [for BPM]**

<b>BPM6 Terminology</b>	<b>BPM7 Terminology (Individual economic account)</b>	<b>Economic Accounts Groups</b>
Goods and services account	Goods account / services account	Current account
Primary income account	Earned income account	
Secondary income account	Transfer income account	
Capital account	No change	Capital account
Financial account	No change	Accumulation accounts
Other changes in financial assets and liabilities account	No change	
International investment position	No change	Balance sheets

21.11921.121 Examples of the changes agreed affecting specific terms in the [SNA]/[BPM] are shown in **Table 21.9**.

**Table 21.9 Changes to specific terms [Terms will be included in the SNA / BPM as appropriate]**

<b>Terminology SNA 2008 / BPM6</b>	<b>Terminology SNA 2025 / BPM7</b>
Accumulation accounts	Accumulation of economic assets account

Adjusted disposable income	Disposable income adjusted for social transfers in kind
Allocation of (other) primary income account	Allocation of (other) earned income account
Balance on goods/services/goods and services	Balance of international trade in goods/services/goods and services
Balance of primary incomes	Balance of earned incomes
Compensation of employees	Remuneration of employees
Constant prices	In volume terms
Consumption of fixed capital	Depreciation
Distribution of income account	Earned income account
Financial intermediation services indirectly measured (FISIM)	Implicit financial services on loans and deposits
Financial lease	Finance lease
Generation of income account	Generation of earned income account
Imputed rental of owner-occupied dwellings	Owner-occupied housing services
Net errors and omissions	Statistical discrepancy
Net fees	Fees less service charges
Net guarantees	Guarantees less service charges
Net (non-life) insurance premiums	Non-life insurance premiums less service charges
Net re-insurance premiums	Re-insurance premiums less service charges
Net social contributions	Social contributions less service charges
Other changes in assets account	Other changes in assets and liabilities account
Other changes in the volume of assets account	Other changes in the volume of assets and liabilities account
Primary income	Earned income
Product balance	Balance of the supply and use of products
Purchases less sales of goodwill and marketing assets	Acquisitions less sales of goodwill and marketing assets
Redistribution of income account	Transfer income account
Redistribution of income in kind account	Social transfers in kind account
Resource lease	Natural resource lease
Resources	Revenues

Secondary distribution of income account	Income transfers other than social transfers in kind account
Trade margin	Distribution margin
Use of adjusted disposable income account	Use of disposable income adjusted for social transfers in kind account
Uses	Expenditures

## Chapter 22: Digitalisation

### BPM7 Chapter 16 – Digitalisation

(new chapter)

*Note: This draft chapter has been prepared jointly to cover the full range of topics to be included in the SNA and BPM chapters on digitalization. Only those issues that are relevant for external sector statistics will be included in the BPM; likewise, only those issues that are relevant to national accounts will be included in the SNA.*

#### A. Introduction

- 22.1 Falling costs and rising capabilities to process, transmit, and store digitized data have resulted in ~~the~~ extensive integration of digital technology into goods and services and the activities of production and consumption. This transformation of economic activity and daily life through the pervasive application of digital technology is referred to as digitalization. Digitalization has been enabled by ~~many types of~~ information and communications technology (ICT) goods and services, including ~~the internet~~, semiconductor chips, computing and electronic communication equipment, software, ~~the internet~~, and wireless digital telecommunication services.
- 22.2 A wide variety of digital products and activities have appeared as part of digitalization, and digital assets, ~~(defined as assets that exist only in digital form (such as crypto assets); and data and software)~~ have assumed important roles as stores of wealth or inputs in production. The profound impact of digitalization on production, consumption, ~~transacting~~, investment, prices, finance, and other aspects of the economy, as well as its impact on international trade in ~~goods and~~ services and other cross-border transactions, calls for enhanced visibility of digital activities, products, and transactions in the macroeconomic accounts. Guidelines are therefore needed on measuring the activities, products, and assets associated with digitalization in the conceptual framework of the SNA/BPM and on enhancing the visibility of digital activity and products in the macroeconomic accounts.
- 22.3 Measurement issues associated with digitalization, or that touch on digitalization, are also discussed in other chapters of the SNA/BPM and in other manuals. To increase the visibility of digitalization, chapter 11 of the Balance of Payments and International Investment Position Manual, recommends showing computer and information services as a first-level services category in the balance of payments current account. The capital account chapter in the SNA and the chapters on goods and services account in the BPM discuss the main types of non-financial assets that have enabled or resulted from digitalization, which include ICT equipment, software, data and databases, crypto assets without a corresponding liability, and digital elements of research and development. The financial accounts chapter of the SNA and the chapter on classification of financial assets and liabilities in BPM discuss classification of crypto assets with a corresponding liability and electronic money (e-money). The SNA chapter on measuring prices, volumes and productivity discusses measurement challenges that affect products associated with digitalization, such as adjusting price comparisons for quality change. Finally, the 2023 edition of the [Handbook on Measuring Digital Trade](#) discusses digital intermediation platforms and other aspects of trade affected by digitalization and the *OECD Handbook on Compiling Digital Supply and Use Tables* discusses tools to increase the visibility of digitalization in macroeconomic accounts.
- 22.4 To provide a consolidated view of measuring and reporting on key aspects of digitalization, and to cover additional aspects of digitalization, this chapter considers the main conceptual and measurement issues presented by the products, activities, and assets, including related cross-border transactions, that have emerged as part of digitalization and recommends tools for increasing the visibility of digitalization in national accounts/external sector statistics. The rest of this chapter is organized as follows. Section B ~~introduces digital transactions, activities industries~~ and products. Section C ~~considers~~ discusses ~~two types of nonfinancial digital online~~ platforms, ~~including~~ non-financial digital intermediation platforms ~~and free online platforms~~, along with ~~free online platforms and~~ other free products associated with digitalization. Section D discusses digitalization and the financial system, with subsections on new financial services and means of payment enabled by digitalization, financial digital ~~intermediation~~ platforms, and fungible digital assets,

including crypto assets. These sections (B, C, and D) also highlight the issues relevant for external sector statistics. Section E provides an overview of the issues and challenges presented by digital products for the measurement of prices and volumes and their solutions. Section F concludes the chapter with a section on analytical tools to increase the visibility of digitalization, including a thematic account based on the digital supply and use tables (SUTs), and an extended account showing an alternative treatment of the consumption of free services of digital platforms.

**Commented [A1]:** This will not be included in BPM7

## B. Digital Transactions, and Industries and Products

22.5 An analysis of digital transactions is a key part of understanding the current state and evolution of digitalization, as digital transactions enable many of the activities and products associated with the digital transformation. Digital transactions include both digitally ordered and digitally delivered transactions and can encompass both goods and services. Digitally ordered transactions are transactions ordered over a computer network by methods specifically designed for receiving or placing orders. Digitally delivered transactions are transactions that are delivered remotely over computer networks.

22.6 E-commerce transactions are characterized by digital ordering. An e-commerce transaction is the sale or purchase of a good or service conducted over a computer network by methods specifically designed for the purpose of receiving or placing orders. E-commerce transactions can be ordered from a retail or wholesale trader, directly ordered from the producer or supplier of the good or service, or ordered via a digital intermediation platform (DIP). E-commerce margin services are supplied by retail and wholesale traders that receive orders digitally.

22.7 Digital industries (or activities) include the producers of the goods and services that enable digitalization. For example, digital transactions are made possible by digital networks and complementary ICT products. Digital industries also include the industries enabled by digital networks. One such industry consists of e-tailers, which are retail and wholesale traders that receive most orders digitally. Other digital industries discussed below are DIPs, platforms based on data collection and advertising, and financial service providers that predominantly operate digitally. In addition, the analysis of digital industries discussed as part of the digital SUTs includes a row for producers dependent on DIPs and a row for other producers operating only digitally. Services supplied over a computer network are a defining feature of the digital economy. These digital economy services include wholesale and retail e-commerce distribution services.

**Commented [A2]:** This sentence may not be included in BPM7

### *Digital Products*

22.8 This section defines the digital products that could be included in an analysis of the supply and use of digital products or of international trade in digital products. Some products that have emerged as part of digitalization raise measurement questions. This section also includes subsections on the measurement of some specific digital products.

22.9 Digital products either enable digitalization or are enabled by digital technology and infrastructure. The products enabling digitalization include ICT goods (both ICT equipment and components), software, data and databases, and telecommunication and network communication services. ~~ICT components may be embedded in non-digital goods (such as semiconductor chips in motor vehicles). The products enabled by digitalization include services delivered over a computer network, such as cloud computing (which is also an enabler of many digital services), digital intermediation and other services of online platforms, audio and video streaming, online conferences, online learning, and digital financial and payment services.~~

22.10 Digital products can be divided into ICT goods and digital services, with digital knowledge-capturing products such as computer programs, data and databases included in digital services unless sold on physical media such as a disk. The ICT goods are the goods included in the ICT products of the alternative structure for products of the information economy in the Central Product Classification (CPC) version 2.1. Digital services include the ICT products that are services – ICT services, digitally delivered content and media products such as online video games and online content, and services of validating transactions in digital assets. Knowledge-capturing products are grouped with services even though they have some of the characteristics of a good. ~~priced and free services of online platforms, audio and video streaming, and digital financial and payment services~~

22.5 — ICT equipment, software, and data and databases along with ICT consumer durable goods, and mobile and fixed line digital communication services ICT components embedded in non-ICT equipment (such as semiconductor chips in motor vehicles)

22.622.11 Digitalization has also resulted in, and been accelerated by, the emergence of cloud computing as a new way of accessing information technology (ICT) resources. It has also resulted in new types of assets. The conceptual and measurement issues raised by cloud computing, data assets, artificial intelligence (AI) systems, and non-fungible tokens as a type of digital asset are discussed in this subsection. Online platforms are discussed in subsection C.D and digital financial services and fungible digital assets are discussed in subsection D.E.

## 1. Cloud computing

22.722.12 Cloud computing technology has enabled a shift in the location where most computing occurs from the user's premises to remotely located data centers accessed over a network, sometimes referred to as "the cloud." Furthermore, the growing use of cloud computing services has caused large scale substitution of purchased ICT services for ownership of hardware computing and communication equipment and software assets. Cloud computing services are used in the production or delivery of many of the digital services delivered over the internet are produced with inputs of cloud computing services. Cloud computing services are primarily used as an input into the production of other goods and services (i.e., for intermediate consumption).

22.822.13 Cloud computing services consist of computing, data storage, software, and related ICT services accessed remotely over a network, supplied on demand and with measured resource usage. Measured resource usage allows pay-per-use charging based on actual resources consumed, although charges for some services, such as data storage, may instead be based on predetermined limits on the IT resources accessed (e.g., data storage). Measured resource usage also helps allocate resources efficiently because cloud computing technology takes advantage of resource pooling. Another characteristic of cloud computing technology is rapid elasticity, which means that users with fluctuating or fast-changing computing needs can scale their consumption up or down as circumstances warrant.

22.922.14 The main cloud computing products can be divided into three broad categories: i) infrastructure-as-a-service (IaaS), which gives the user on-demand access to hardware such as a virtual server; ii) platform-as-a-service (PaaS), which also includes access to a software platform; and iii) software-as-a-service (SaaS), which includes access to the application software. Users of IaaS or PaaS provide their own software license, or software original. Function-as-a-service (FaaS) is a simplified type of PaaS that allows application functionalities to be executed in response to events. In addition, business-process-as-a-service (BPaaS) enables organizations to automate business processes using cloud computing software and platforms (i.e., SaaS and PaaS).

22.1022.15 Cloud computing is part of a broader shift to remote computing that also includes the growth of colocation and hosting services. Remote datacenters can offer advantages such as physical infrastructure that supports large-scale computing, high network bandwidth and optimized connectivity, low cost, and security. To benefit from such advantages, IT users may lease space for their equipment in a colocation datacenter, or they may lease servers and other ICT equipment from a supplier of managed or unmanaged hosting services. IT users often consume a combination of the three types of remote computing services – for example, their colocated or hosted equipment may connect with a supplier of cloud computing services.

22.1122.16 Cloud computing users with a long-term contract for dedicated access to a server in a cloud computing datacenter are considered to be economic owners of the server if the operating risk is borne by the user, making the contract a financial lease. Also, rather than paying per-use licensing fees to access a software product supplied by the cloud computing enterprise, cloud computing users may hold long-term license for a software product that they access in the cloud. If the term of the software license is more than a year, the license conceptually represents a software asset of the user, and one-year software licenses that automatically renew are also treated on the same lines, for practical reasons. Software subscriptions from software publishers that come with a long-term license are software assets, not intermediate consumption of software services (which is the case with licenses of less than one year). This follows the treatment of software licenses

outlined in paragraph 10.100, 2008 SNA (and its update in 2025 SNA chapter 11). ~~The treatment of cross-border transactions in such licenses (more than one year/less than one year) is under discussion and will be included in Chapter 11, Services Account, BPM7.~~

**Commented [A3]:** This is deleted as BPM7 will not add any guidance on such licenses.

~~22.12.22.17~~ The fixed capital formation of cloud computing enterprises may include own-account production of software and equipment or equipment designs. For example, a large cloud computing enterprise may design equipment that meets its needs and outsource the physical production to a contract manufacturer. This enterprise's production of original equipment designs ~~is may be measured by its cost and may be categorized as either own-account investment in equipment or part of~~ own-account R&D capital formation.

~~22.13~~ Data center construction is also part of the fixed capital formation associated with cloud computing. Real estate enterprises that specialize in the construction and operation of data center buildings often lease data center buildings to cloud computing enterprises. If the cloud computing enterprise bears the operating risks, the lease should be treated as a financial lease.

~~22.14~~~~22.18~~ The shift from purchasing software and hardware as ICT fixed assets to consuming cloud computing services presents challenges for the analysis of the contribution of ICT fixed capital formation to economic growth and total factor productivity (TFP) growth. To provide the detailed data on consumption of cloud computing and hosting services needed to understand the changes in how ICT resources are accessed and the general role of ICT in production may require adding product detail on cloud computing and related services to existing classifications. This could be done as part of the digital supply and use table (SUT) ~~or the digital economy thematic account~~ discussed in Section F.

~~22.15~~~~22.19~~ Cloud computing and other remote computing services are often supplied across borders, and important suppliers of these services are multinational enterprises with domestic and foreign computing establishments connected by cross-border networks. The consumption of these services takes place in the location of the production process into which they are an input. For example, if a business in country A purchases computing services from a cloud computing establishment in country B, the computing services will be an export of country B and an import of country A. ~~In balance of payments, these services are recorded as part of the standard component computer and information services (refer to Chapter 11, Services Account, BPM7) for further details). The resource pooling aspect of cloud computing technology, which means that workloads can shift between servers or even establishments, can make it hard to know where the physical production of a computing service occurred. However, the flows of spending on exported and imported cloud computing should be possible more feasible to track. Also, ensuring that the estimates of exports and imports of cloud computing services are consistent with the value of net exports implied by the difference between the economy's production and consumption of cloud computing services may improve these~~ ~~their accuracy estimates~~ For an economy that is just an importer of cloud computing services (and not a producer of these services), this implies that the data on intermediate consumption of these services in the economy (assuming that the services are consumed by businesses) could furnish a reliable estimate of imports

**Formatted:** Line spacing: Multiple 1.08 li

**Commented [A4]:** This sentence will be omitted from the SNA

~~22.16~~~~22.20~~ Hosting and colocation services are exported when foreign-owned ~~IT assets, such as~~ servers and software, are hosted in a domestic data center. Similarly, these services are imported when locally owned ~~ICT~~ assets are hosted in a foreign data center. The investment in the ~~ICT~~ assets should be recorded in the economy of their owner.

## 2. Data assets

~~22.17~~~~22.21~~ The emergence of data as an important type of intellectual property product is among the ways in which digitalization has transformed the economy. In the digitalized economy, many enterprises owe much of their value to their holdings and uses of data, and many products and production processes depend on data. ~~Digital-These~~ enterprises' data assets enable them to match suppliers, products, or information to buyers' needs. ~~In particular, e-tailers and online platforms use data to produce matching services, either of customers with the product that suits their needs, of users with each other, of producers with consumers, of advertisers with viewers, or of funders with borrowers Moreover, and producers of all types, including governments, use data for purposes such as developing and implementing product or program improvements, improving operational efficiency and customer experiences, planning, and marketing.~~

22.22 Data as an asset is defined as information content that is produced by accessing and observing phenomena, and recording, organizing, and storing information elements from these phenomena in a digital format and that provides an economic benefit when used in productive activities. Digitized information that does not provide a direct economic benefit to its owner, including ancillary data generated as a by-product of the producer's operations, is excluded.

22.23 Data ~~assets are~~ is produced when information on observable phenomena (OP) such as facts, behaviors, and characteristics is recorded, organized, and stored in digital format. In the next step in the data-information value chain, database assets are created by structuring and formatting the data to enable efficient retrieval and analysis. Databases consist of files of data organized in such a way as to permit resource-effective access and analysis. They do not include the data or the database management system (DBMS) software. The cost of producing databases includes planning and implementing the structure and design of the database and preparing the data to facilitate its analysis.

22.1822.24 In the last step of the data-information value chain, the owner of the data Producers ~~derives economic benefits from data assets by creating databases that bring together data from different sources and that are organized and structured to facilitate analysis, and by extracting insights and knowledge via their analysis of the data. (The owner of the data could also derive economic benefits by selling the data, in which case different steps of the data-information value chain will be performed by different data owners.) The types of intellectual property products created as part of by producing and analyzing data this value chain include databases, software, research and development, and mineral exploration. The cost of acquiring data used only once to develop an intellectual property product is~~ may be included in the value of the intellectual property product.

22.1922.25 Despite their conceptual difference, data and databases are difficult to measure separately because they are produced with similar inputs and because transactions prices generally reflect the combined value of the database and the data. For reporting purposes, data and databases are therefore combined into a single detailed intellectual property (IP) product called data and databases. This detailed product is then combined with software including artificial intelligence to form a higher-level class of IP product. (Refer to Table 11.4, Treatment of Intellectual Property, in BPM7, for details on the recording of data and databases in balance of payments and to the discussion of intellectual property products in SNA2025 chapter 11 for general guidelines.)

**Commented [A5]:** This phrase will be omitted from the SNA

22.2022.26 Most data assets are produced internally. The value of own-account data assets is measured by their cost of production. This cost includes the expenses to develop a data production strategy, to collect and record the information elements of interest, and to gain access to information on the OP.

22.2122.27 Data assets can also be acquired in purchase transactions. Purchasing data may represent either fixed capital formation or intermediate consumption of data services depending on the duration of the use of the data in production and the limitations on the purchaser's use of the data. The sale of the data original, which would include rights to sell copies of the data or licenses access to use the data and all other ownership rights, transfers ownership of the data asset to the purchaser. Copies of long-lived data with general rights to use the data in production for more than a year are also classifiable as fixed assets of the purchaser. However, a non-exclusive right to access a copy of the data for a limited or specific purpose will generally be treated as a service. The right to use a purchased copy of the data for less than a year is a service analogous to an operating lease. The sale of information derived from data, which must be distinguished from a sale of the data, is a service. Cross-border transactions in data assets are recorded in the services account (refer to BPM7 chapter 11 Services Account for further details).

**Commented [A6]:** May not be included in BPM7

22.28 Digital platforms ~~often~~ usually collect data on their users ~~and the content they create~~. If the subjects of the data collection receive payments for granting access agreeing to the collection of data on ~~to~~ their OP, those payments are also part of cost of producing the data asset. However, pPayments for authorization to collect data on users' OP are classified as distributions of income rather than as services and hence included in rents. Agreeing to collection of one's data (such as when visiting a free online platform after accepting the license agreement) does not fall within the definition of production and is therefore not a service. (Platform users who receive payments for undertaking specific actions to assist the collection and recording of data on their OP do supply a service, but such cases are likely to be too rare in practice to be worth distinguishing.)

**Commented [A7]:** This sentence will be omitted from the SNA

22.2222.29 Payments for a license to collect data on access to data collection on an individual's OP are classified

with rents because being the subject of the data collection is not to be considered as being equivalent to supplying a service. However, but this treatment should not be taken to imply that permission to collect a subject's license data confers access to a non-produced, nonfinancial asset, as specified in the definition of a rent in paragraph 8.17. Although rents are payments for access to a non-produced nonfinancial asset, in the case of payments for authorization to users' data, the right to control one's data, and the general right to privacy, are not the type of asset that is recordable on a balance sheet as ownership rights cannot exercised over them. Privacy rights are not an asset that can be recorded on the balance sheet.

~~22.23~~22.30 The SNA asset boundary for fixed assets includes produced assets used in production for more than a year, so data that will be used in production for more than a year is conceptually a fixed asset. However, many types of data (including behavioral data used for targeted advertising) tend to have a relatively short service life. The value of the goods and services produced with inputs of shorter-lived data conceptually includes the value of that data. Therefore, When it is feasible, to treat the cost of production of data whose service life is clearly short (e.g., data that is stored for only a short time) should be treated as intermediate consumption rather than fixed capital formation, it will be appropriate to do so.

**Commented [A8]:** Limited details to be included in BPM7

~~22.24~~22.31 An establishment's enterprise's own-account production of data may include both data with a service life shorter than a year and data with a service life longer than a year. In practice, In these cases, the information needed to separately identify the costs of producing the short-lived data and the costs of producing the long-lived data is often unavailable. When the separate cost of producing the short-lived data is unknown, a relatively short average service life that reflects the inclusion of the data with a service life shorter than a year may be used to estimate the value of the combined stock of data assets. the cost of producing long-lived data may be hard to estimate separately from the cost of producing short-lived data, making it necessary to estimate the combined cost of producing data and then split the combined estimate into short-lived and long-lived components based on an assumed ratio. As an alternative to splitting the combined estimate of the cost of producing data based on a ratio of production of short-lived data to production of data in general, a relatively short service life data assets as estimated in practice may be assumed to reflect the presence of types of data with a useful life of a year or less. Although including expenses that do not create economic benefits in future years in the estimate of fixed capital formation has the disadvantage of causing producers' gross value added to be overstated, this disadvantage is outweighed alternative to the ratio approach does have by the advantage of capturing the potentially important value of the stocks of data whose useful economic life is a year or less inas part of the measure of the stocks of the data assets. Service lives for data of under a year are common, so if the measure of the production of data does not exclude all the data with a service life of a year or less, a relatively short assumption for the service life of data assets is likely to be appropriate.

~~22.25~~22.32 Expenditures to update or add to an existing own-account data asset are also capitalized. Suppliers of software and connected equipment with embedded software or AI systems often collect data on users to update or add to their data assets. Expenses to collect users' data for these purposes are part of investment in data assets. Data and databases are conceptually distinct types of intellectual property products, but they are produced using similar inputs and measuring them separately is often difficult. Moreover, transactions in databases generally include the value of the data stored in the database. Data and databases are therefore combined into a single detailed class of intellectual property (IP) product known as data and databases. This asset type is then further combined with software including artificial intelligence to form a higher-level class of IP product. (Refer to Table 11.4, Treatment of Intellectual Property, in BPM7, for details on the recording of data and databases in balance of payments and to the discussion of intellectual property products in SNA2025 chapter 11 for general guidelines.) Nevertheless, data is separately identified in the label of these IP product classes because "data" refers to the information content that has been recorded in digital form while "databases" refers to the design, structure, and organization of the files to permit efficient access to the data they contain. The costs of producing a database include planning and implementing the structure and design of the database and organizing the data to facilitate its use.

**Commented [A9]:** May not be included in BPM7

**Commented [A10]:** This paragraph was moved up

**Commented [A11]:** This phrase will be omitted from the SNA

### 3. Artificial intelligence (AI)

~~22.26~~22.33 ~~22.35~~ Artificial intelligence refers to capabilities of a computer program, or system controlled by a computer program, of recognition, reasoning, communication, and prediction that emulate human

recognition, reasoning, and communication. Machine learning, in which data enables an AI software program to learn to predict or classify from experience, is often used to develop or improve AI programs, and AI systems rely on a combination of software and data to generate their output. Furthermore, deep learning (a type of machine learning) enables some AI programs to improve from experience while being used in production. Although they perform tasks that normally require human intelligence, AI programs often use data beyond a scale that humans could analyze.

~~22.2722.34~~ Many of the innovative products and product capabilities associated with digitalization are made possible by AI technologies. Among these are text mining, computer vision/image recognition, speech recognition, natural language processing, personalized recommendations, and content creation with the help of generative AI. Applications of AI include translation, predictive modeling, risk assessment by lenders and insurers, data analytics, writing summaries of the content of large textual data ~~basesets~~, smart robots, autonomous drones and vehicles, face recognition, fraud detection, and cybersecurity. AI has greatly expanded the types of jobs or job elements potentially subject to automation ~~and it also has the potential to affect patterns of international trade by facilitating digital ordering and changing relative costs of production.~~

~~22.2822.35~~ The transformative impact of AI calls for the provision of granular data ~~on AI intellectual property assets~~ to permit analysis of ~~questions about the use~~ ~~the prevalence~~ of AI and ~~of questions such as~~ the effect of AI on labor markets ~~and production or international trade~~. To support the provision of this data, AI systems ~~are should be~~ distinguished as a special type of software within a class of intellectual property product identified as “Computer Software, including Artificial Intelligence Systems,” with the separate reporting of AI encouraged as an “of which” item. AI is also distinguished as a type of intellectual property product in the definition of this product group. AI is classified as a special type of software even though AI systems frequently include data and hardware elements, because the system is controlled by software even when these elements are present. However, the equipment that contains an embedded AI system (or other embedded software) is still classified as equipment.

~~22.2922.36~~ The general compilation guidelines for software, data and databases in chapter 11 of the 2025 SNA/chapter 11 of BPM7 also apply to AI software, but AI uses data and machine learning in ways that present some special issues. Data plays a critical role in training AI software, and ~~data databases are~~ often ~~acquired and organized in a database created~~ for the specific purpose of training an AI software program. In addition, AI programs often ~~refer to a use~~ database to generate their output. The value of the data used to train an AI software product or to help AI software to generate its output should be recorded separately from the value of AI software, as the data could have multiple uses. However, ~~data assembled in a database created~~ solely as a step in the production of an AI computer program and that cannot be re-used may be included in the costs of producing ~~AI programs, if the sum of costs methodeest of production is used to value the relevant assets~~ AI program.

~~22.3022.37~~ ~~In contrast to fixed assets’ usual pattern of deterioration in performance over time due to obsolescence or physical decay,~~ ~~(The performance of an AI software program with learning capabilities may improve as the program is used. Fixed capital formation is not recorded in connection with learning from experience by AI software for pragmatic reasons, as the associated cost is likely to be small. However, the depreciation rate of the AI software fixed asset may be adjusted. Learning from experience may can costlessly extend the service life of an many AI programs, making it appropriate to assume a long life for the asset. (Learning from experience by AI software is not the only source improvements in the performance of software that is already being used: many software products receive automatic software updates delivered over the internet may also have this effect.)~~

#### 4. Nonfungible tokens (NFTs)

~~22.3122.38~~ Nonfungible tokens (NFTs) are digital records hosted on a blockchain that are associated with a digital or physical asset or product but that are distinct from that asset or product. NFTs certify ~~ownership of~~ rights to use and benefit from the asset and may also serve to certify the asset’s authenticity. They are nonfungible because the associated asset is unique and not interchangeable with other assets in the same class the way that the units of a fungible crypto assets are. Payments for NFTs usually must be made in the fungible crypto asset native to the blockchain on which the NFT is hosted ~~(see paragraph 22.85 for the description of fungible crypto assets).~~

~~22.3222.39~~ NFTs are classified into three classes: (1) those that convey no ownership rights and only allow for

**Commented [A12]:** These parts may not be included in BPM7

personal use of ~~another specified~~ asset or product; (2) those that convey limited ownership rights, beyond personal use for a ~~another specified~~ asset or product; and (3) those that convey full ownership rights for ~~another specified~~ asset or product. The main classification of NFTs is based on the type of rights conveyed rather than on the characteristics of the associated asset or good. The purchase of an NFT could, based on these rights, be classified as consumption, as an acquisition of a non-produced asset, or as neither (assuming that the ~~purchase of the~~ associated asset ~~has~~ already ~~been~~ recorded). However, NFTs vary widely both in the ownership rights they convey and in the type of digital and physical asset or good to which they are linked.

~~22.33~~22.40 NFTs that convey no ownership rights and only allow for personal use of ~~another specified~~ asset or commodity (e.g., the right to display a video clip of a scoring play in a sporting event or of a piece of digital art for non-commercial purposes) are in the first category. The purchase of an NFT that only gives rights to personal use of an item is treated as consumption. This type of NFT is not an investment item because it cannot be used in production and generally does not serve as a store of value. However, in rare cases, an NFT in this category that commands a high price when first auctioned and that has enough exclusivity and appeal to have a lasting value may qualify as a valuable. Treating the initial purchase of NFTs in this class as a consumption expenditure implies that their creation represents ~~the production of a service~~. In the case of cross-border transactions in this type of NFT, such services are recorded under ~~relevant category depending on the content of the related asset-computer-and-information-services~~.

~~22.34~~22.41 The second type of NFT conveys limited ownership rights to ~~another specified~~ asset or commodity that go beyond personal use to include use for commercial purposes. NFTs that convey limited ownership rights are in the SNA/BPM asset class containing contracts, leases and licenses if they confer valuable benefits that the holder can realize in practice. Assets in this class are non-produced, nonfinancial assets. The ownership rights conveyed to the NFT holder may affect the value of the encumbered asset. Further information on contracts, leases and licenses is provided in SNA chapter 27/BPM chapter 14.

~~22.35~~22.42 The third type of NFT conveys full ownership rights. NFTs that convey full ownership are a method of recording and verifying ownership of an underlying asset. ~~The~~ ~~at~~ ~~underlying~~ asset should already be recorded in the national accounts. An NFT that conveys full ownership is a digital recording of ownership similar to a property title, not a separate asset. Purchasing an NFT in this category is therefore a way of purchasing the underlying asset. In the case of cross-border transactions in this type of NFT, if the underlying asset is digital ~~or physical~~, it is treated based on the ~~existing~~ principles for recording such assets ~~(goods or computer services)~~. If the underlying asset is a physical asset (e.g., a house property), ~~treatment follows the existing principles for recording such assets~~.

**Commented [A13]:** BPM7 will included only the details on recording the cross-border transactions in NFTs.

## C. Digital Platforms

~~22.36~~22.43 Operators of ~~d~~Digital platforms — also known as online platforms — use digital technology to supply a digital services that facilitate interactions via the internet between two or more distinct but interdependent sets of users (either firms or individuals); who interact through the service via the internet. Because they Platforms help users to connect with and interact with other users, ~~P~~platforms are ~~therefore~~ subject to network effects. (~~Network effects which arise occur~~ when the value of a platform or product to each user ~~depends on~~ increases as the number with of other users of the platform or product ~~rises or family of products~~.) The opportunities for beneficial interactions with other platform users increase with the number of users in general or the number of users on the other side of the platform, so adding users makes the platform's services more valuable. For example, increasing the ~~number of sellers on a platform makes it more attractive to buyers and increasing the number of buyers makes it more attractive to sellers; similarly, increasing the audience size raises the prices that advertisers are willing to pay for the platform's services~~. Online platforms deliver their services via the internet, and digital platforms also known as online platforms.

22.44 Digital platforms — also known as online platforms — supply a digital service that facilitates interactions between two or more distinct but interdependent sets of users, who interact through the service via the internet. Digital (or online) platforms ~~are conceptually distinct~~ differ from ~~suppliers of e-commerce margin services (or e-tailers)~~ e-commerce firms because ~~e-commerce firms~~ they do not take possession of the goods or ~~directly produce the services sold on the platform~~. They also differ from other producers operating digitally because they intermediate, rather than produce, the goods and services sold on the platform. ~~they sell~~

However, An establishment that sells its own merchandise and an establishment that facilitates selling by others can, however, both be part of the same multi-establishment enterprise. Furthermore, e-commerce firms and online platforms and e-tailers both use data to produce matching services, either of customers with the products that suits their needs, of users with each other, of producers with consumers, of advertisers with viewers, or of funders with borrowers. To take advantage of the synergies in technology, an establishment enterprise might combine that selling its own merchandise via digital ordering (i.e., an e-tailer) and establishments that operate operating a digital platform that facilitates selling by others, may be part of the same multi-establishment enterprise.

22.45 Digitally-enabled Digital intermediation services facilitate transactions between multiple buyers and multiple sellers in exchange for a fee, without the unit providing the intermediation services taking economic ownership of the goods or rendering the service being intermediated. These services of matching producers and with consumers with each other or funders with borrowers and facilitate their transactions are known as digital intermediation. Digital intermediation is a service in which digital technology and data are used to match parties that desire to transact with each other and to facilitate their transactions.

22.3722.46 Some digital platforms are free, while other fee-based platforms facilitate financial transactions or interactions that do not involve a transaction. There are therefore three-four types of digital platforms:

- a. *Nonfinancial digital intermediation platforms (DIPs)* facilitate transactions between multiple buyers and multiple sellers for the ordering and delivery of goods and services for a fee or commission, without taking ownership of the goods, or rendering and the services, that are being sold (intermediated).
- b. *Free online platforms* facilitate non-commercial interactions between users or provide entertainment and information services and are usually funded by advertising and the collection of data on their users.
- c. *Financial digital platforms* Finally, financial digital intermediation platforms intermediate mediate funding or payment transactions for a fee. Financial digital platforms DIPs are discussed below in the section ED on digitalization and the financial system.
- e.d. *Other fee-based digital platforms* facilitate interactions between users other than transactions in goods and services or financial transactions. Online dating and matrimonial platforms are an examples.

## 1. Nonfinancial digital intermediation platforms (DIPs)

22.3822.47 In addition to helping buyers and sellers of goods and services to find each other, nonfinancial DIPs facilitate ordering, payment for, and delivery of, goods and services supplied by institutional units on the seller side of the platform to institutional units on the buyer side of the platform. DIPs charge fees for these digital intermediation services. To increase parties' willingness to transact, they may also provide quality assurance through steps such as vetting the parties that have access to the platform.

22.48 The output of a DIP consists of digital intermediation services, which are recompensed through a fee. It does not include the goods and services that the DIP helps others to sell. The possible consumption of the platform's services by the users on the two sides of the platform is shown on the sides of the triangle in Figure 22.1. The seller/producer and the buyer/consumer both consume intermediation services in the case in which that where they are separately invoiced for the services supplied by the platform. In the cases where that in which all fees for the platform's services are invoiced to the seller/producer, only the seller/producer is recorded as consuming the intermediation services, and similarly, only the buyer is recorded as consuming the intermediation services in the cases where that in which all fees for the platform's services are invoiced to the buyer. However, in all cases, the buyer using the DIP consumes the good or services supplied by the seller/producer using DIP, as shown at the base of the triangle.

22.3922.49 Nonfinancial DIPs often accept customers' buyers' payments for the goods and services produced or sold by platform users and deduct their intermediation service fee from the amount passed through to the producer/seller of the goods and services. To capture the economic substance of the transactions in which the platform passes on the payment for the good or service after deducting its fee or commission, these payment

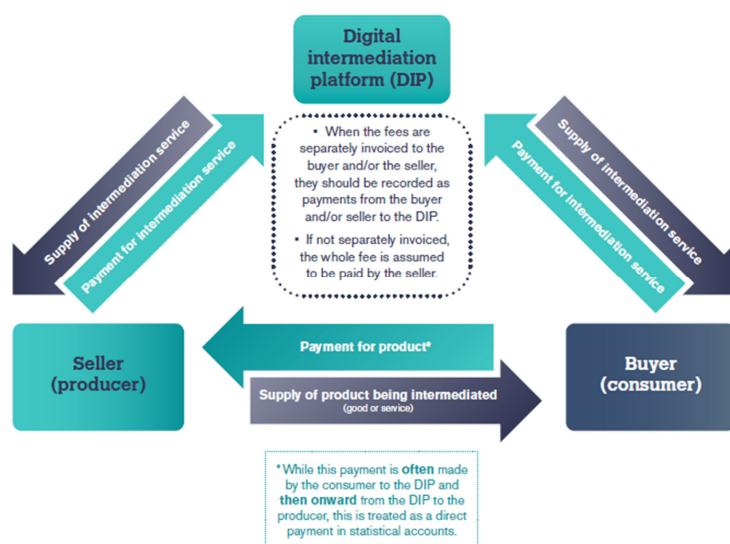

**Commented [A14]:** All the details of this sub-section may not be included in BPM7

flows must be rerouted to include a direct sale of the output good or service by of the producer/sellers using the platform to the buyers using the platform and a purchase by those producer/seller of the intermediation services supplied by the platform. The approach to recording the transactions of a DIP in which the producer of the intermediated good or services consumes is treated as the purchaser of the platform's intermediation services is known as the producer approach. The transactions recorded for a DIP after any necessary rerouting to implement the producer approach are those shown on the left side and at the base of in Figure 22.1.

Figure 22.1. The Possible Types of Producer Approach to Transactions of a Digital Intermediation Platforms

Formatted: Keep with next

Source: *Handbook on Measuring Digital Trade*, 2<sup>nd</sup> edition..

22.50 Handling the case when the platform's fee is implicitly included in the price of the intermediated product by recording transactions in which the buyer purchases the product directly from its producer or seller and the producer/seller purchases intermediation services from the platform has some important advantages. This approach allows the production supplying of the goods and services sold on DIPs to be recorded in the appropriate industry and the consumption of those goods and services to be recorded in the appropriate class of commodities. It also accounts for the effect of the intermediate consumption of the services of the DIP on the producer's value added. (A complete picture portrayal of the services of DIPs and the value of the products ordered through DIPs may be provided in as part of a thematic account on the digital economy or a set of digital supply and use tables.)

22.4022.51 The buyer is recorded as purchasing intermediation services from the DIP in cases when the DIP separately invoices the buyer for its services. However, in these cases the buyer's payment for the good or services must still be rerouted to record a purchase of the good or service from its producer/seller, and, if a fee is deducted from the amount passed through to the producer/seller, a purchase of intermediation services by the producer/seller. In addition, sSome DIPs seek to attract -buyers to the platform by using a portion of the fees received from sellers to pay rebates to buyers. The rebates represent a reduction in the price of the

goods and services supplied by the seller and are also not part of the fee (or price) that the platform retains for its intermediation services. The price received by the seller must therefore be measured by the net price after the rebate, and the fee recorded as received by the platform for its services must exclude the amount that funds the rebates. The rebate payment must therefore be re-routed to show that it is paid by the platform to the seller and then paid by the seller to the buyer, with each rebate representing a reduction in the price received by its payer. The recording of the transactions of the DIP and its users follows a different approach when the DIP invoices the buyer separately for its services and for the intermediated product. In this case, the buyer is recorded as purchasing intermediation services from the platform and as purchasing the intermediated product from its producer (or seller). The DIP may also charge a fee for its services to both the buyer and the seller of the intermediated product. In this case, three transactions are recorded because both the buyer and the seller are recorded as purchasing intermediation fees from the DIP, and the buyer is recorded as also purchasing the intermediated product from its seller.

22.4122.52 Digital intermediation services are frequently supplied across international borders by non-resident platforms. Goods and services supplied by resident producers ~~and consumed by~~ resident buyers via transactions intermediated by a non-resident platform should be recorded as produced and consumed in the compiling economy. Further, the fee or commission received by the DIP should be recorded as an import of digital intermediation services of the compiling economy. ~~Therefore, if the non-resident platform deducts its fee from the buyer's payment for the good or service, the buyer's payment must be rerouted so that the producer/seller is recorded as selling the good or service to the buyer and importing the digital intermediation service.~~ (Refer to BPM7 Chapter 11 the Services Account, for details on the specific recording in balance of payments.) ~~Similarly, in the case of a resident DIP collecting a cross-border payment for the goods and services on behalf of a non-resident producer/seller providing a good or service to a non-resident buyer and deducting its fee from that payment, that it intermediates, this will require rerouting the buyer's payment is rerouted to go to the producer/seller and that an export of the services of the DIP to the economy of the seller/producer is recorded, the goods and services are not treated as being imported at the net price received by their producer and then exported at a marked-up price paid by their buyer.~~

**Commented [A15]:** This sentence will be omitted from the SNA

22.4222.53 Digital intermediation ~~services platforms~~ can also facilitate exports by resident suppliers of goods or services, or imports from foreign suppliers of goods or services. Digital intermediation services used by an exporter ~~are~~should be included in the value of the exported good or service. For example, if a DIP located in country A facilitates the supply of a service by a resident of country B to a resident of country C, the price paid by the buyer in country C is the value of service exported by country B and imported by country C. ~~and~~ The fee or commission charged by the platform is then the value of digital intermediation services exported from country A and imported by country B. Domestically produced digital intermediation services used by the producer of an imported good or service should conceptually be treated as an export of services and ~~included in~~ the value of the imported good or service should be measured by price paid by its buyer. However, this treatment may require rerouting the fee or commission paid to the DIP to pass through the foreign producer. If the source data to compile these rerouted flows are unavailable, assumptions (or international cooperation) may be needed to impute the rerouted flows.

22.54 ~~In general,~~ SServices sold for a fee or commission are usually straightforward to measure, but ~~in the case of measuring the intermediation services of~~ DIPs and the goods and services transactions that they intermediate can present compilation challenges ~~are common~~. Rerouting the payments collected and fees retained by a DIP to the producers of the intermediated goods and services may require data that are generally unavailable, making assumptions necessary. Also, producers of services supplied via a DIP may be hard to distinguish from employees of the producer of the digitally order services. determining whether intermediation services are being provided may be difficult because transactions between platform users may be hard to distinguish from transactions in which the platform takes possession of the good or uses the service as an intermediate input to produce a different service, or is acting as an employer. These latter cases should be treated as e-commerce activity.

22.4322.55 Furthermore, by allowing producers to interact with previously unreachable consumers, including those in other geographical locations, DIPs have provided selling opportunities to producers previously excluded from the market. Selling opportunities created by DIPs have led to growing activity by informal household enterprises, which are likely to be missing from business registers and other standard sources of statistical information. They have also contributed led to the rapid growth of small international transactions in goods and services that may be below the minimum thresholds for customs duties and documentation

requirements. Another common compilation challenge from DIPs providing cross-border intermediation services is that source data on DIPs with no local presence and on the activity that they intermediate is not easily available.

## 2. Free online platforms and free digital products

<sup>22.44</sup><sup>22.56</sup> Digitalization has been marked by ~~a broad-based expansion in the availability of free products, in many cases provided by online platforms~~<sup>the emergence of free online platforms as part of daily life and a general expansion in the availability of free digital products</sup>. The SNA framework that values the free outputs of nonmarket producers such as nonprofit institutions funded by donations by the cost of production does not apply to most of these free digital products because they are supplied by a commercial enterprise. The outputs of commercial enterprises are valued by their price, which is zero in the case of a free product. The emergence of free online platforms and products as part of digitalization has therefore raised questions about whether the output of the digital economy is fully included in GDP.

<sup>22.45</sup><sup>22.57</sup> Free products supplied by market producers are included in GDP as part of the price of other products they help sell or with which they are bundled either directly or indirectly. Taken together, the items in the bundle generate at least enough revenue to cover the operating costs of the supplier of the free product, so the overall output of the supplier of the free digital product is not undermeasured. Free products are supplied by both platform firms and non-platform firms.

### Free products supplied by non-platform firms

<sup>22.46</sup><sup>22.58</sup> In the non-platform case, the free output and the priced output are marketed to the same set of customers, and the function of the free output is to promote sales of the priced output to those customers. Suppliers of digital products frequently adopt a “freemium” pricing strategy, in which a free basic version of the product promotes sales of upgrades or a premium version of the product. In these cases, the price of the promoted output includes a mark-up that covers the cost of supplying the free output that has facilitated its sale.

<sup>22.47</sup><sup>22.59</sup> Rather than being free, the promotional output may have a low price that is subsidized by the fully priced product. For example, ~~a low-priced basic version of a software product may require the purchase of an upgrade or a complementary software product to unlock desirable features or capabilities, printers may boost the sales of high-priced ink cartridges, with the price of the printer supplies funding the subsidy to the printer’s price. Taken together, the sales of the items in the bundle give the value of the producer’s output.~~

<sup>22.48</sup><sup>22.60</sup> Although a zero or artificially low price of an output that is cross subsidized by the price of another output of that same producer does not cause undermeasurement of the producer’s total output, it does affect the measurement of the composition of the producer’s output. The relative values ascribed to the items in the bundle can matter for the measurement of fixed capital formation if a free or cross-subsidized item used for fixed capital formation is bundled with items used for intermediate consumption, such as the supplies needed to operate a piece of equipment, or the training, maintenance and helpdesk services needed to use a free software product. Also, the relative values assigned to the various parts of the bundle could affect the measurement of exports, imports, or trade patterns if a multinational enterprise sources parts of the bundle from different countries. Finally, the effect of these relative values on the weights of the price and volume indexes could matter for measurement of the volume growth of GDP if the prices of the items in the bundle behave differently.

### Free online platforms

<sup>22.49</sup><sup>22.61</sup> Most free online platforms are organized as commercial enterprises. Two-sided (or multi-sided) commercial platforms often charge a price for their services to the users on one side of the platform and supply free services to the users on the other side of the platform to attract and retain those users. The platform users attracted by free services increase the value of the platform’s services to the users on the priced side of the platform. The users who fund the platform by purchasing priced services recoup this expense as part of

**Commented [A16]:** Only limited details from this subsection will be included in BPM7

the transactions with the users on the free side of the platform enabled by the platform's services.

22.62 Free online platforms offer services such as social media, search, and access to content providing entertainment and information. Commercial free online platforms are generally funded by advertising and the collection of data on their users, while ~~offline non-digital~~ free radio and television broadcasters are funded just by advertising. The data is used as input in the platforms' production of advertising services. However, the data, or information derived from the data, may also be sold or used for own-account production of software and R&D.

22.5022.63 Platforms funded by advertising services frequently assemble the audience that the advertisers want to reach by supplying free services. They then include the cost of supplying the free services needed to assemble the audience in the price charged to advertisers. The advertisers, in turn, include the cost of the platform's advertising services in the price of the product sold with the help of the advertising. Both the platform and the firms that advertise on the platform receive at least enough income from the prices at which their output is sold to cover their operating costs. The standard method of measuring the value of a market producer's output by the producer's sales is therefore applicable to both the platform and the funder side users of the platform. Furthermore, households' expenditures on the products advertised on the platform include the cost of the platform's services embedded in the price of the advertised products.

22.5122.64 Digital platforms ~~that~~ collect and store data on users to produce data assets as a type of own-account investment, ~~and they~~ may also license others sell rights to use the data or even sell the data. The value of own-account investment in data assets is usually measured by the cost of production. However, the platforms may also compile collect short-lived data on recent browsing behavior that is used as an intermediate input for targeted advertising. The value of this short-lived data is part of the price of the advertisement targeting services. More generally, short-lived user data collected by digital platforms can be assumed to be used for intermediate consumption, with its value embedded in the price of the products it helps produce.

22.5222.65 A few free online platforms (such as public wikis created and maintained by communities of volunteers) are owned by a nonprofit institution serving households and operate as non-market producers, meaning that their output is not sold for an economically significant price. The output of non-market producers is valued by the cost of production. Nevertheless, the production costs of nonprofit free platforms may be modest in comparison with physical indicators of its output such as number of visits or scale of content it hosts because volunteers may do much of the work. The work of volunteers is outside the production boundary of the SNA but could be included in an extended account on unpaid household service work.

## Content created by platform users

22.5322.66 Many uUsers of free platforms create content such as videos, images, text, and audio, both as a leisure activity and for commercial purposes such as receiving advertising revenue. Creating content for leisure purposes is outside the SNA production boundary. If the content creator does not receive remuneration, the content is assumed to be created for leisure purposes. Households that receive monetary remuneration from an advertiser or platform for use of their uploaded content may be considered unincorporated household enterprises supplying services to the advertiser or platform. In the case of a platform that takes its fees for services out of the payments from advertisers that are passed through to the content creators, the content creators should be treated as the purchasers of the platform's services and the producers of the services used by the advertisers. If the purchaser is a non-resident, the service should be included in exports of services.

22.5422.67 Depending on the context, user-generated content can refer either to content created by the users of a brand's products (customers and brand advocates), or to content created by the users of an online platform. The economic benefits that free platforms receive from platform user-generated content include attracting users to the platform, selling advertising, and adding to the platform's stock of data assets. These economic benefits are a positive externality of the sort that frequently arises from producers' interactions with their customers and are not a basis for inferring that the creator of the unpaid user-generated content has produced a service used by the platform. However, the cost of supplying free services to the platform users who create content may be included in the platform's own-account investment in data assets. Furthermore, an extended

account with an alternative approach to measurement of households' consumption of the services of free platforms can optionally treat user-generated content as a service produced with inputs of the platform's free services and used by the platform as an input in its own-account production of data assets.

22.5522.68 In addition to posting content on free platforms that receive advertising revenue, content creators may publish on digital platforms that collect subscription fees on their behalf in return for a share of the fees. Although most of this content is likely to have a short economic life, content created for commercial purposes that yields economic benefits for the content creator over more than a year is an intellectual property asset of the creator classified as long-lived entertainment, literary and artistic originals.

## Free Software

22.5622.69 Software products are often free to download, although the services of the platform hosting the software code may not be free. The free software may be used by households for final consumption, or it may be used in production. Copies of free software are frequently supplied across borders. In addition, free code shared by software developers on code hosting platforms that facilitate collaboration plays an important role in software development.

22.5722.70 App stores are a type of DIP on which some of the software items where the service that is intermediated available for (the app that households to download to their phone or other device are ) is often free. Free and subsidized apps used by households may be funded by advertising, by and collection of data on their user, by purchases of premium versions or other items that they encourage, or by other services whose use they facilitate. Like the services of an online platform funded by advertising, the services of apps funded by advertising are purchased indirectly as part of the price of the advertised product.

22.5822.71 Open-source software refers to free software whose source code is publicly available under a license to copy, use, inspect, modify, and share. Open-source software is used in production by corporations, governments, and nonprofit institutions. It is usually developed, maintained, and supplied by a corporation, university, government unitresearch office, or nonprofit institution whose investment to develop the open-source software original would be included in a general estimate of own-account software investment based on costs of production, such as the compensation expense for software developers.

22.5922.72 A complex open-source software product may contain components developed in multiple economies, as the development of complex software products is often spread across multiple locations. Depending on the circumstances, it may be appropriate to allocate the investment to develop the open-source software product among the economies in which the development work takes place, or it may be appropriate to attribute the entire investment to the economy of residence of the owner of the software asset. In the case of software produced by a multinational enterprise, the headquarters or one of the foreign affiliates may acquire full ownership of the software original by funding the software's development.

22.6022.73 Even though open-source software does not generate licensing fee income for its developer, it can qualify as an asset of its developer. The producer of an asset is an economic owner if the producer bears the risks of production in order to claim benefits associated with the use of the asset. Open-source software developed by corporations is usually funded through sales of complementary services, such as training and support, or by other products it helps sell. Open-source and other free software may also help increase the number of users on a platform or enhance the developer's reputation and profile. Open-source software supplied across borders may be funded by cross-border sales of complementary services or other products.

22.6122.74 Open-source software is sometimes developed by individuals working independently. Unpaid production of open-source software originals by volunteers is outside the SNA production boundary. However, independent developers of open-source software for commercial purposes are unincorporated household enterprises investing in own-account software.

22.6222.75 The value of open-source software copies supplied by enterprises may be embedded in the price of complementary outputs that the open-source software helps sell or that are bundled with the open-source software. These purchased outputs may be software or services used for intermediate consumption. If software users substitute open-source software funded by mark-ups on intermediate consumption items for explicit purchases of software, the standard procedures will still correctly measure the total output of the

supplier of the free software but the breakdown of the uses of that output will omit the use for software investment. Measured software investment will also be reduced if software users substitute open-source software distributed by a government entity or nonprofit institution operating as a non-market producer for purchased software. ~~The SNA values outputs of nonmarket producers such as the free software by their cost of production, not the willingness to pay of the users of these outputs that could be inferred from the price being paid for a competing substitute commercial product with similar capabilities even if such a price would be available.~~

### Increasing the Visibility of Free ~~online~~ **Online platforms** and Products

~~22.63~~22.76 The value of the free services that advertising- and data-funded digital platforms supply to households is relevant for analytical purposes and for understanding the broader impact on household consumption of the emergence of these free platforms. Alternative measures of household final consumption expenditures and the output of free online platforms that include the households' direct consumption of the services of advertising- and data-funded digital platforms may be presented in an extended account on free online platforms, as discussed in Section F below.

~~22.64~~22.77 The effect of free platforms and free digital products on volume growth of household consumption is also conceptually relevant for understanding the impact of digitalization on prices and volumes. Free digital products and the measurement of prices and volumes is discussed in section E.

## D. Digitalization and the Financial System

### 1. New Financial Services and Means of Payment Enabled by Digitalization

~~22.65~~22.78 Digitalization has resulted in the appearance of new financial service products and ~~of~~ new digital assets designed to be used as a means of payment. ~~Means of payment refers to the instrument used to make the payment, such as a check, debit, or credit card.~~ The new digital financial service ~~products~~ fall within existing categories of products, and the new digital assets fall within existing asset categories. However, they should be reported as "of which" items (or as part of the product detail in a thematic account on the digital economy and the associated digital supply and use tables) when they are important and can be separately identified. ~~(BPM7 recommends introducing "of which" categories for i) fintech companies within the subsector classification; and ii) instruments or services classifications where necessary to separate out fintech-related instruments and services.) (see paragraph 5.154 for the definition of fintech).~~

~~22.66~~22.79 It will usually be appropriate to provide a breakout of ~~financial service providers predominantly operating digitally, which will contain the providers of financial services that primarily transact with consumers via digital channels as part of the digital supply and use tables or thematic account on the digital economy discussed below.~~ ~~Financial service providers predominantly operating digitally include financial digital platforms.~~ ~~The important types of suppliers of digital financial services include financial digital intermediation platforms,~~ digital providers of insurance ~~and reinsurance~~ services (InsurTech), digital banking platforms operating solely online (neobanks) ~~or predominantly online,~~ e-money issuers, and online only foreign exchange bureaus and money transfer operators. Some important digital payment mechanisms are e-money (which includes mobile money), digital assets that are used as a means of payment including fungible crypto assets, and central bank digital currencies (CBDCs).

**Commented [A17]:** We may not require this reference for BPM7

### 2. Financial Digital ~~Intermediation~~ Platforms

~~22.67~~22.80 Financial digital ~~intermediation~~ platforms provide matching services and facilitate financial transactions between suppliers of funds and users of funds. They do not take ownership of the financial assets arising from claims on the users of funds or incur liabilities to the suppliers of funds. They receive fees or commissions for their services and are classified as financial auxiliaries (S126). They differ from conventional financial intermediaries, which incur liabilities on their own account and acquire financial assets and which charge for their financial intermediation services implicitly through interest rate margins.

~~22.81~~ There are ~~three-four~~ types of financial digital ~~intermediation~~ platforms ~~that facilitate access to funding in exchange for a fee or commission~~: (1) peer-to-peer and other online lending platforms, (2) equity-based crowdfunding platforms, and (3) philanthropic ~~(or donation-based)~~ crowdfunding platforms, ~~and (4) reward-based crowdfunding, in which the donors to a project expect to receive a non-financial reward such as a good or service~~. Peer-to-peer lending platforms facilitate loans between households ~~or from households to small enterprises~~. Other lending platforms match households and small enterprises seeking funding to institutional investors seeking lending opportunities. Equity-based crowdfunding platforms facilitate financing transactions in which the funders receive equity stakes in the enterprises or projects they fund. The ~~donation and gift funding~~ transactions mediated by philanthropic crowdfunding platforms are current transfers or, potentially, capital transfers, and an element of the services these platforms perform is vetting of causes that are seeking assistance. ~~The funds advanced to project owners on reward-based platforms do not qualify as loans, as the project owner's obligation to supply the reward is contingent on the successful completion of the project.~~

~~22.68~~

~~22.82~~ Another type of financial digital ~~intermediation~~ platform ~~whose main purpose is not to facilitate access to funding~~ consists of crypto asset exchanges and trading platforms. Crypto asset exchanges and trading platforms allow users to buy, sell and stake (lend) crypto assets for a fee or commission. ~~They embed their fees into their buying and selling prices. Some crypto exchanges may provide custodian services and hold crypto assets of customers for a fee.~~ Crypto assets with a corresponding liability (e.g., asset-backed stable coins, debt, and equity security crypto assets) are classified as financial assets (see paragraph 22.76 for the classification of crypto assets). Since financial assets are generally among the assets traded on ~~a~~ crypto asset exchanges ~~and trading platforms~~, ~~crypto asset exchanges~~ ~~they~~ are classified as financial auxiliaries.

~~22.69~~ Crypto asset brokers allow users to buy crypto and sell crypto assets at prices set by the broker and may also hold customers' cryptocurrencies. ~~They act as intermediaries between buyers and sellers of crypto assets and embed their fees into their buying and selling prices.~~

### 3. Digital Representations of Value

~~22.70~~~~22.83~~ Digital assets designed to act as a medium of exchange or financial instrument are digital representations of value recorded on a cryptographically secured distributed ledger or using a similar technology or issued by a central bank as a CBDC. ~~Medium of exchange is defined as a means for acquiring nonfinancial assets (goods, merchandise equipment, etc.), services, and financial assets without resorting to barter.~~ Digital assets differ from e-money. E-money is monetary value stored electronically on a physical device such as card or phone or stored remotely, which represents a liability of the e-money issuer and is denominated in a fiat currency. E-money must represent general purchasing power (i.e., it can be used for making payments to a variety of other entities).

~~22.71~~~~22.84~~ Crypto assets are digital representations of value that use cryptography and distributed ledger technology (DLT) such as blockchains to enable parties to transact directly with each other without the need for a trusted intermediary. DLTs allow transactions to be recorded, synchronized, and shared simultaneously on multiple nodes in a decentralized network. Blockchains create cryptographic records of transactions and ownership that are impossible to alter ~~without detection~~.

~~22.72~~~~22.85~~ Crypto assets are classified as either fungible or non-fungible. Fungible crypto assets are divisible and not unique (e.g., one bitcoin is equal to any other bitcoin and can be divided into equal pieces of similar value). Conversely, non-fungible crypto assets, commonly known as nonfungible tokens or NFTs, are unique and non-divisible (see Section B.4). Fungible crypto assets are classified into three broad categories: (1) those designed to act as a general medium of exchange (which are further divided in those with, and those without, a corresponding liability); (2) those designed to act as a medium of exchange within a platform or network (again divided into those with, and those without, a corresponding liability); and (3) security crypto assets. Security crypto assets are tokens certifying ownership of a financial instrument. They always have a corresponding liability and should be recorded as debt securities, equity securities, or financial derivative depending on the nature of the claim on the issuer.

~~22.73~~~~22.86~~ A digital assets decision tree to aid in identifying fungible crypto assets according to the above

typology and other digital assets that have a corresponding liability appears in Figure 22.2. Digital assets with a corresponding liability include CBDCs, security crypto assets, payment tokens with a corresponding liability, and most stablecoins. Payment tokens entitle the holder to future access to a good or service. Stablecoins aim to maintain a stable value relative to a specified asset such as a fiat currency or gold, or a specified basket of assets, usually by being backed (or, at least, advertised as backed) by the assets of the issuer. The stability mechanism might also be an algorithm that causes the supply of the asset to respond automatically to changes in demand for the asset.

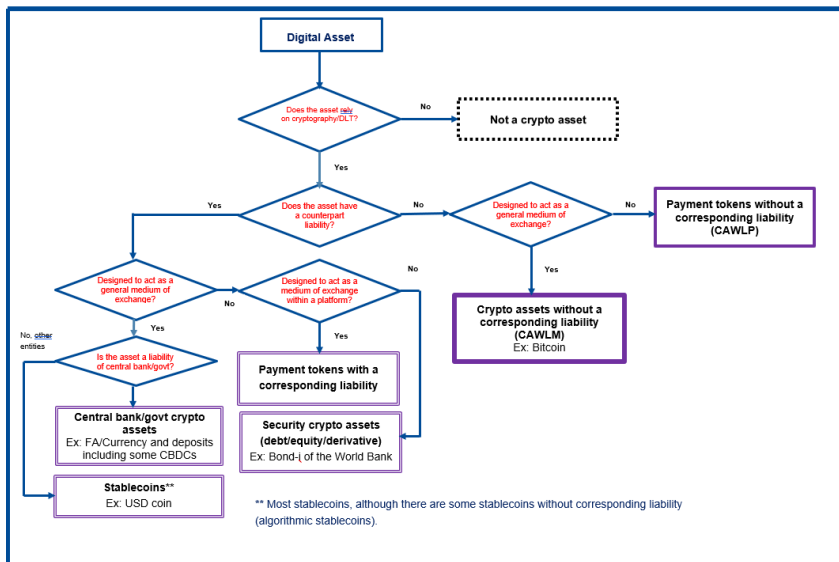

~~22.74~~22.87 All types of crypto assets are within the SNA asset boundary. Crypto assets with a corresponding liability are classified as financial assets. ~~In particular, crypto assets with a corresponding liability designed to act as a general medium of exchange are separately identified under “currency and deposits” and those designed to act as a medium of exchange within a platform are treated as equity or debt security crypto assets;~~ while ~~On the other hand,~~ crypto assets without a corresponding liability are classified as non-produced, non-financial assets within a separate category. If a crypto asset without a corresponding liability is ever able to gain widespread acceptance as a general medium of exchange, the guidance on its classification may be reconsidered. The capital account, financial account, and balance sheet chapters of the SNA (chapters 11, 12, and 14) and the classification of financial assets and liabilities (chapter 5) and the capital account (chapter 14) chapters of the BPM provide additional details.

~~22.75~~22.88 ~~Validating~~ Validation of crypto asset transactions is a service. The process of validating transactions in crypto assets is known as mining in the case of crypto assets without a corresponding liability that rely on proof of work for ensuring the security of transactions. This process includes the release of new units of the crypto asset as an implicit fee paid to the miner validating the transaction. The miner validating the transaction also receives an explicit fee in crypto assets paid by the party initiating the transaction, which is normally the sender/seller. The validation services that are rewarded with newly released units of the crypto asset are assumed to be collectively consumed by the existing holders of units of that crypto asset, while those rewarded by the explicit fee are consumed by the transactor paying the fee (normally the sender/seller). Refer to Chapter 7, *2025 SNA* and Chapter 11, *BPM7* for details on the recording of output of mining and cross-border validation services.

**Commented [A18]:** In BPM7, they will be included under this class with the following footnote: Countries where cross-border flows in these assets are relevant, may report them as a supplementary item under currency and deposits.

**Commented [A19]:** This part of the sentence will be omitted from the SNA

Figure 22.2 Decision Tree for Classifying Fungible Digital Assets

## E. Measuring Prices and Volumes of Products affected by Digitalization

22.7622.89 Many of the measurement challenges arising from digitalization involve prices and volumes rather than the output at current prices. Price and volume measurement challenges are particularly common for products affected by digitalization because price change is straightforward to measure only when the products and their characteristics remain static. Digitalization has transformed household consumption and caused rapid change in products' characteristics and sources of supply. New digital products regularly disrupt existing ones, new models or service contracts frequently embody quality improvements, digital intellectual property products and services with no physical units of measurement are growing in importance, and free products often appear or cease to be free.

22.7722.90 Regular and timely refreshment of the samples of models (and outlets) used to calculate the price indexes for products subject to frequent quality improvements to keep them representative of current purchasing patterns is the first step in compiling deflators that capture these products' quality change. Secondly, the appearance of new models and the exit of obsolete models must be handled in a way that allows the price index for the product to reflect the value of the quality changes.

22.7822.91 The commonly used "matched models" procedure for handling entry of new models and exit of old ones when constructing the price index for a product considers only the price changes of the continuing models in calculating the change in the index. ~~Any models~~ not present in both periods ~~are~~ excluded from the subsample used to calculate the change in the index. Leaving these models out of the index calculation ~~has the advantage of~~ avoiding the risk of counting price differences ~~due to~~ caused by quality differences as inflation, i.e., as a price change caused by the passage of time. However, the method implicitly assumes that the quality-adjusted price of the new model equals the price of the model it is replacing (after adjusting for the general change in price of the product between the last period with the exiting model's price was observed and the first period when new model's price is observed). Newly introduced models of products benefiting from advances in digital technology often offer substantially improved quality at about the same price as the model they replaced.

22.7922.92 To capture the price and volume impact of quality changes in digital products, the prices of new models must be adjusted for the value of their quality difference from the models they replace. Hedonic

regression models relating the price to the product's characteristics are a recommended method for adjusting prices for quality change. Hedonic models that use machine learning methods to predict the price of the new model in the previous period and the price of the old model in the current period have been proposed as a technique for doing quality adjustment at scale when analyzing large datasets covering e-commerce transactions.

~~22.80~~22.93 Another technique used to adjust the price of a digital product for a quality change is options pricing, which averages observations on the differences in the price of the item caused by the presence or absence of a characteristic offered as an option. This is the same sort of adjustment that is implicitly made by a hedonic regression (the results will not be the same if logarithms of prices are used in the hedonic model but not the options pricing model (on hedonic regression, see chapter 18)). Regardless of the quality adjustment procedure used when a quality change is observed in the data used to compile the price index,

~~22.81~~22.94 A price measurement problem known as outlet substitution bias occurs when buyers obtain a substantially identical product at a lower price from a new source of supply. The lower cost supplier may have appeared as part of digitalization. For example, a ride sharing DIP may offer lower prices without a significant sacrifice in quality compared to the taxis, or a good may sell for less online than offline. The impact on the average price paid of a shift in households' shopping patterns to new source of supply can be captured by compiling a unit value price index (in which the total expenditure is divided by the total quantity purchased.) However, the composition of a unit value index must be homogeneous, as the maintained assumption is that all the items included in its calculation have the same per-unit intrinsic value. (Under the weaker assumption that the average quality of items being purchased is not falling, a unit value index can provide an upper bound measure of inflation in price of the product.)

## 1. Measuring quality change in ICT goods and goods with ICT components

~~22.82~~22.95 Frequent quality changes in ICT equipment and ICT durable goods enabled by rapidly advancing semiconductor chip technology have ~~presented been a challenges~~ for price index compilers ever since ~~the emergence of computing devices based on this technology was first commercialized.~~ New models of ~~these~~ICT goods have often offered a substantial improvement in performance at almost the same price as the previous model, yet the widely used "matched models" method for price index compilation implicitly assumes that the quality-adjusted prices of the two models in an overlap period are the same. Furthermore, ~~the spread the measurement problem of quality changes enabled by semiconductors beyond ICT goods has spread as digitalization has proceeded, as embedded semiconductors and software now enable quality improvements into~~ many kinds of equipment and durable goods with ICT components, including motor vehicles, is an important element of digitalization.

~~22.83~~22.96 Hedonic regression methods or the option price method can be used to estimate the value of quality changes associated with model replacements to enable the price indexes for ICT goods and goods with IT components to capture their quality improvements. In the case of microprocessors, rather than just considering physical characteristics, performance benchmarks or indicators are sometimes included in the hedonic quality adjustment model. If ~~hedonic and options pricing~~these methods are not feasible, information on the cost of production of a new product feature may be used to adjust the product's price index for the quality change. For example, a new capability of a motor vehicle made possible by embedded semiconductors and software might be valued by the producer's cost of adding this feature plus the usual distribution margins included in the retail price.

## 2. Software and data

~~22.84~~22.97 Software and data assets play critical roles in the success of many digital firms. The growing importance of software has expanded the range of uncertainty around the deflator for investment in IT products because the volume and quality of different software packages are hard to assess, and in-house production of software is common. The price or volume growth of own-account software and data must generally be inferred from the prices and volumes of the inputs, either assuming no productivity change or using the rate of productivity change of a related activity. Another option for deflating custom software is to use the price index of a related product, such as standardized software products sold by software publishers.

Continuous improvement in the performance of AI software that learns from experience is not included in the volume of software investment.

22.8522.98 Data is a heterogeneous type of asset, with wide variation in value depending on the topic, context, and circumstances. The volume and value of gross investment in creating data assets are measured by the volume and value of the inputs used to produce the data assets. This could be smaller than the income that the data is expected to generate. If the data is sold, however, the price received may imply the need to record a revaluation, holding gains and losses may change the value of the data, and a normal obsolescence causes the volume of a data asset to decay, will have a downward effect on its volume.

### 3. Cloud computing

22.8622.99 Many of the enterprises that supply cloud computing services offer a largegreat variety of detailed products within the broad categories of IaaS, PaaS, and, especially, SaaS. Thus, the length and complexity of the menu of products is likely to pose a challenge for construction of a price index for cloud computing services. Frequent introductions of new or modified products and improvements to existing products compound the difficulty. However, serviceable deflators for cloud computing services can usually be compiled by selecting However, price data from representative samples of major products-varieties with relatively standardizedstable characteristics from each product category and adjusting for quality changes as necessary. can be used to estimate a deflator for cloud computing output.

22.8722.100 Cross-border transactions are another common challenge for estimation of deflators for output and consumption of cloud computing services. International collaboration may be required to overcome the problems of price data availability so that deflators for the consumption of cross-border cloud computing can be compiled. .

### 4. Internet and telecommunications services

22.8822.101 The volumes of internet and telecommunications services consumed by households- have risen rapidly, substantially as households spend more time online and utilize more data via broadband and mobile connections, as e-commerce expands, and consume more digitally delivered content data processing moves to the cloud, and telecommuting becomes routine. Data transmission speeds have also improved. Commonly used methods for constructing consumer price indexes and producer price indexes for telecommunications services may, however, fail to capture this volume growth. To measure the change in the cost of purchasing a given volume of internet and telecommunications services accurately, samples of contracts, products and carriers must be kept up to date and prices must be adjusted for quality changes such as improvements in data transmission speeds or improvements in the geographic coverage offered by a mobile telecommunications provider.

22.8922.102 If the available price indexes for internet and telecommunications services fail to capture the quality improvements that are appropriate to include in the measure of volume growth, an alternative to deflating by a price index is to estimate the volume growth of internet and telecommunications services directly. Theis volume index iswould be constructed from physical-quantity indicators such as megabytes of data usage. To minimize the risk of distortion from changes in the composition of the aggregate being measured, the physical volumequantity indicators should be defined at a detailed level, and the growth rates of the physical indicators for the various detailed products should be aggregated using expenditure or revenue weights.

### 5. E-commerce and digital intermediation platforms

22.103 Both business-to-household and business-to-business e-commerce transactions enable producers to access markets they could not otherwise serve, and prices may behave distinctively in the markets accessed through digital channels. The prices used to construct the price index for a type of good or service must therefore adequately represent the e-commerce transactions. Similarly, suppliers that predominantly sell through digital channels, including e-tailers, digital platforms, and sellers/producers dependent on DIPs, must be must adequately represented in the samples of suppliers.

22.104 Deflators for household final consumption expenditures on items sold online must give appropriate weight adequately represent to prices from e-tailers, e-commerce outlets and other sellers/producers selling online, including those selling through DIPs, suppliers, and from suppliers selling on digital platforms, because online prices may have different trends from offline prices. Furthermore, the high frequency of changes in online prices will often make a monthly unit value a more suitable measure of the price of an item in a month from an online supplier than the supplier's price at a point in time during the month. Finally, if item-level data on expenditures are available for the online sellers, the index weights should reflect this expenditure data and an index formula or algorithm that is resistant to chain drift should be used. (Chain drift is the distortion caused by fluctuations in the weights in a chained index.) Online prices from e-commerce retailers Prices from online retailers and sellers on DIPs platforms such as ridesharing and short-term rental platforms drivers are often lower than offline prices for similar/comparable items. The change in the average price paid by households when households substitute a source of supply with a different price level for their old source of supply for an identical item conceptually represents a decline in the deflator for household final consumption expenditures. In practice, however, practical difficulties and concerns about possible unobserved differences in quality usually keep price index compilers from capturing the possible price decline associated with the switch to online sources of supply.

22.105 A common practice in constructing price indexes for a good or service is to treat the price at a single point in time during the month as the price for the entire month. However, online prices tend to change more frequently than once a month. For items with frequent changes in their online price, a monthly unit value will provide a suitable measure of the price during the month if the data on expenditures and unit sales needed to calculate the unit value are available. When available, item-level expenditure data can also furnish detailed weights for a price index or volume index.

## 6. Expanded access to variety and customization

22.9022.106 Digitalization has given buyers access to vast arrays of products available for purchase and to abundant information on products and sellers and The information provided by digital platforms and e-commerce suppliers enables households to locate the detailed varieties whose characteristics best match their tastes and needs from among the vast array of products available for purchase online. Digitalization has also increased opportunities for product customization. This expanded access to variety and information has improved buyers' ability to find the specific varieties and suppliers whose characteristics best match their needs or tastes. By e The upward effects on the level of material wellbeing achievable with a given level of spending from expanding households' access to variety and improving the matching of product characteristics with the shoppers' tastes and needs are beyond the scope of the deflator for household final consumption expenditures. However, they are relevant for understanding the effects of digitalization on the growth of material wellbeing.

or tastes. This has increased of the households that consume them, digitalization has improved the efficiency with which output is goods and services are used once it has they have been produced. The effective decline in the cost of household final consumption due to the expanded variety and information available to purchasers following digitalization is beyond the production boundary of GDP but could be part of in an expanded measure of economic activity that considers that the change in households' material well-being or economic welfare linked to digitalization, associated with digitalization extended account. Such an expanded measure of economic activity would be presented derived in an extended account, on

Households' material well-being (or welfare) from consumption of goods and services has therefore grown faster than production of goods and services. This source of welfare gain could be relevant for an extended concept of consumption volume used for analytical purposes. The welfare gains from better use of output once it has been produced are, however, not part of the production that is measured by the national accounts. Similarly, the welfare gains from inventions of new digital products with novel characteristics are beyond the scope of the price and volume measures of the SNA.

## 7. Free digital products

~~22.94~~22.107 Conceptually, the increased availability to households of free products brought about by digitalization represents a decline in the price and an increase in the volume of the household final consumption basket. The effect of appearance of a free product is straightforward to measure in the case where the free product directly replaces a priced product. When an item that households must purchase separately becomes free, the same total expenditure will command a greater volume of goods and services and the effect on the household consumption deflator will be given by the decline in the cost of the bundle. However, when the services of free online platforms start to be bundled in the prices of advertised products, the theoretical decline in the cost of the bundle will depend on the assumed value of the free online platform services. An extended account that values the free services of digital platforms by their cost of production is discussed below in the subsection on “Analytical Tools to Increase the Visibility of Digitalization.”

~~22.92~~22.108 The free digital services and embedded product capabilities in devices such as the smartphone that have appeared since the start of digitalization often enable households to achieve outcomes that previously required purchases of market goods and services. They may also save time or allow their user to do things that they previously could not do. However, the assumptions required to measure the effects on the household final consumption deflator of the appearance of a free digital product that is not a direct replacement for any priced product would often have unacceptable effects on the replicability of the results. Theoretical effects on deflators and volume growth associated with the appearance or disappearance of free digital products that are impossible to measure without hard-to-justify assumptions are beyond the scope of the measures of the national accounts.

## F. Analytical Tools to Increase the Visibility of Digitalization

~~22.93~~22.109 Digitalization is a multidimensional phenomenon that requires multiple indicators and perspectives to understand. Furthermore, the standard national accounts aggregates provide limited information on the transactions, products and activities affected by digitalization. In the standard classification of industries and commodities published in the national accounts, digital products are often subsumed in broader aggregates and scattered across different aggregates. Enhanced visibility into digital firms, products, and transactions is therefore needed for a full understanding of the effects of digitalization on the economy and of the performance and the evolution of a digitalized economy. Distinguishing the digital components of the standard aggregates will also provide reassurance to the users of the national accounts that the output and consumption of digital products is being fully measured as part of those aggregates.

~~22.94~~22.110 A thematic account on the digital economy, digital supply and use tables (SUTs), and an extended account on free services of online platforms are flexible tools for bringing the impact of digitalization on the economy into focus, where flexibility means that the content that is appropriate to include depends, in part, on which aspects are locally important and practical to measure. These tools complement each other. The conceptual framework of the digital SUTs will help to ensure the accuracy and consistency of the data presented in the digital economy thematic account, while the digital economy thematic account ~~can help~~ can help a tool for communicating the key information contained in the digital SUTs in a convenient and accessible way and for providing additional context. Also, an extended account can present an alternative framework for accounting for the unpriced services that free online platforms supply to households. Households’ consumption of the free services of digital platforms funded by advertising and the collection of data is a major element of the gains in economic welfare associated with the digital transformation.

### 1. Thematic Account on the Digital Economy

~~22.95~~22.111 ~~A thematic account on the digital economy is a flexible tool for communicating the information needed to understand key aspects of digitalization and its impact on the economy.~~ Compiling a thematic account on the digital economy and the related digital supply and use tables (SUTs) can bring visibility to activities, products and transactions affected by digitalization that are subsumed in broader aggregates in the standard classifications of the national accounts. A digital economy thematic account provides alternative aggregations and additional detail on products and transactions ~~that~~ that separately identifies the digital segments of industries, digital products, and digital transactions, and can highlight key information from the digital SUTs. The conceptual framework of the digital SUTs helps guide the compilation of the digital

Commented [A20]: This section will not be included in BPM7

economy thematic account. ~~The digital supply and use tables (SUTs) may supply much of the data presented in a digital economy thematic account.~~ (For general background on the purpose of thematic accounts and the use of SUTs to compile a thematic account, see [chapter 38.](#))

~~22.96~~22.112 In developing a digital economy thematic account, the items that are most important for understanding the impact of digitalization should be prioritized. These items are likely to include breakouts of digitally ordered and digitally delivered transactions, production and intermediate consumption of cloud computing services and digital intermediation services. ~~They may also include, and the output and value added of each of the industries supplying ICT goods and software, business-to-business and business-to-household e-commerce margin services, and other types of digital services such as cloud computing services, telecommunications and internet services, digital intermediation services, digital advertising services, and digital financial services. ICT services, and other digital services.~~ The suppliers of ~~other digital products services may ight~~ be classified ~~into providers of digital infrastructure (digitally enabling industries) into, e-~~etailers, ~~and data- and advertising-driven platforms, non-financial digital intermediation platforms, financial service providers primarily operating digitally, and other service providers operating only digitally.~~

~~22.97~~22.113 The thematic account should summarize the uses of ICT goods and digital services, including uses for own-account and purchased investment. The fixed capital formation that enables digital activity is also relevant for understanding the impact of digitalization. In addition to ICT equipment, software, and data, this fixed capital includes the infrastructure of data centers and networks.

~~22.98~~ Trade flows of ICT goods and digital services are important to include in the thematic account on the digital economy. A decomposition of exports and imports by major category of products may also be important to report to show the source of the differences between domestic production and domestic uses of the items in these categories. International transactions that are digitally ordered or digitally delivered are additional aspects that should be highlighted in the thematic account. ~~Furthermore, the share of domestic transactions that are digitally ordered transactions is an important indicator of the penetration of e-commerce that is also appropriate to include.~~

~~22.99~~22.114 The indicators in the digital economy thematic account need not be limited to products within the SNA production boundary. The free services that digital platforms supply to households valued by their cost of production can be reported as an addendum item.

## 2. Digital Supply and Use Tables

~~22.100~~22.115 The digital supply and use tables (SUTs) analyze the impact of digitalization along the three dimensions of the nature of the transaction (~~digitally ordered, digitally transmitted, delivered, or intermediated by a DIP~~), products, and industries by adding new detail and aggregations to the standard SUTs. This approach ensures that the framework for analyzing digital transactions, products and industries is aligned with existing classifications and takes advantage of those classifications. The supply table classifications enable a decomposition of the domestic and imported sources of supply of digital products, and the use table classifications enable a decomposition of the uses of digital products for intermediate consumption, final consumption, investment, and exports.

~~22.101~~22.116 As conceptually defined, the digital SUTs have cells that can accommodate all potentially relevant transactions, which makes the number of possible entries in the new rows and columns large. To reduce the compilation burden and source data requirements, a set of high priority aggregates has been identified. The recommended high priority items include (a) decompositions of expenditures by the nature of the transaction, (b) output and intermediate consumption of digital intermediation services, cloud computing services, and ICT goods and digital services, and (c) the output and gross value added of digital industries. (For detailed guidance on compiling digital SUTs, see the *OECD Handbook on Compiling Digital Supply and Use Tables*.)

~~22.102~~22.117 E-commerce transactions are defined by digital ordering—~~using methods specifically designed for the purpose of receiving or placing orders.~~ To provide insight into digitally ordered transactions, the digital supply and use tables include new rows that distinguish these transactions, along with a further decomposition into transactions ordered directly from a counterparty, transactions ordered through a resident digital

intermediation platform, and transactions ordered through a non-resident digital intermediation platform.

22.10322.118 Digital delivery of services is also an important aspect of digitalization. The digitally delivered portion of the output of domestic industries and imports may be shown in “of which” columns in the digital supply table, and digitally delivered portion of household final consumption and exports may be shown in “of which” columns in the digital use table.

22.10422.119 To bring visibility to the output and intermediate consumption of digital products, new rows are added to the SUTs on ICT goods, cloud computing services, digital intermediation services, and all other digital services. An addendum on products beyond the standard production boundary may also have rows for free services of digital platforms and free services of online communities of volunteers. Including imputed values of these free services in the digital SUTs will facilitate compilation of an extended account on free digital services.

22.10522.120 The output and gross value added of digital industries and related industries are shown by incorporating seven new columns in the digital SUTs. One column contains the digitally enabling industry, which comprises the producers of ICT goods and services enabling the use of information technology. The other six columns cover online platforms funded by advertising and data collection, digital intermediation platforms, producers that depend on digital intermediation platforms, e-tailers, financial service providers primarily operating digitally, and other producers operating only digitally.

### 3. Extended Account to Increase the Visibility of the Free Services of Digital Platforms Consumed by Households

22.10622.121 Free online platforms funded by advertising and collection of users’ data have become part of daily life and the time spent by households using platforms offering free services such as social media, search, entertainment, and information suggests that households place a high value on the free services of digital platforms funded by advertising and data collection. An estimate of the value of these free services is therefore relevant for understanding and analyzing the impact of digitalization on the growth of household consumption of goods and services. Yet the value of the free services of platforms funded by advertising and collection of users’ data is not estimated as part of compiling the standard sequence of economic accounts because the cost of supplying these services is implicitly included in the price of the advertising services and data sold by the platform and the platform’s own-account investment in data assets. In effect, in the standard sequence of economic accounts, the digital platform is itself the user of the free services, and the benefits that households derive from these services are merely a positive externality of the production of advertising services and data assets.

22.10722.122 To provide information on households’ direct consumption of the “free” services of digital platforms funded by advertising and data collection, compilation of an extended account showing the value of these services is encouraged. Extended accounts are a flexible tool for presenting concepts that extend SNA boundaries, including expanded measures of economic activity and household final consumption expenditures that extend the production boundary.

22.10822.123 Households’ consumption of the free services of advertiser-funded digital platforms can be included in an extended account as part of expanded measures of household final consumption expenditures and output. Although letting these services be consumed twice, once by households as they use the platform and a second time by the platforms as they produce advertising services and data assets, would cause double counting in a measure GDP, expanded measures of economic activity and household consumption that reflect the simultaneous consumption of these services by the households using the platform and by the platform itself are analytically useful.

22.10922.124 In the framework of the extended account, households’ consumption of unpriced services produced by the platforms’ software and hardware assets in exchange for providinggranting a license to collect data on their behavior and characteristics (or observable phenomena – {OP}) can also be included. The licenses to collect the households’ data are viewed as a payment in kind for the platform’s unpriced services and the platform’s unpriced services are viewed as a payment in kind for the licenses to collect the users’ data. However, agreeing to the collection of data on one’s OP is not a service, so the platform’s imputed payment for the license is a rent rather than a consumption expenditure.

~~22.110~~22.125 The imputed values of items that are bartered for each other (the unpriced platform services consumed by households and the opportunities for the platform to collect the households' data) must be the same. Consequently, there are four theoretical ways to value the platforms' unpriced services: (1) the platform's cost of producing the free services, (2) the value that the households place on the free services, (3) the value that the households place on the privacy of their data that they give up, and (4) the economic benefits that the platforms derive from users' attention and ~~access-the opportunity to collect their~~users' data. The need for consistency within the system of measures of the transactions of the free platforms makes the cost of producing the services the most suitable of these four theoretical values for the extended account. Own-account investment in data assets is usually measured by the cost of production approach, so valuing the licenses to collect data on users' OP by the cost producing the platform services exchanged for these licenses would be consistent with the general approach to measurement of own-account investment in data assets. Cost of production is also more practical to estimate than the other three theoretical values of the platform's free services.

22.126 Although the payment in kind from the platform to the households consists of services produced by the platform, the ~~license-to-access~~ given to the platform collect data on the households' OP ~~that is~~ received in return is not a service produced by the households: ~~so and~~ the imputed payment for the ~~eat~~ license is classified as a rent (see paragraph 22.21<sup>9</sup> for additional details). Licensing collection of data on one's OP is not a production activity – ~~households' OP are not a produced asset, so access to observing and recording a subject's characteristics and actions~~ households' OP cannot be considered ~~does not represent~~ consumption of the services of a produced fixed asset. However, if households actively assist in the collection of their data, the steps they take to assist with the data collection can be considered a production of services (but such cases are rare).

~~22.114~~22.127 The expanded measures of free platforms' output and value added in the extended account will include the imputed value of the free services consumed by households. The balance of primary incomes of the platforms will, however, be unchanged. The platforms' extra value added from imputed sales of services to households will equal the platforms' imputed payments of rent for the licenses to collect households' data. Household saving will also be unchanged because the imputed household consumption expenditures on platform services will equal households' imputed income from licensing collection of their data.

~~22.112~~22.128 In addition to allowing collection of data on their OP, households provide economic benefits to free platforms by creating and supplying user-generated content without monetary compensation. In the standard sequence of accounts, households that receive monetary payments for the content they post online are unincorporated household enterprises producing services, but content supplied without payment is beyond the production boundary. To increase the visibility of households' unremunerated creation of user-generated content, the extended account can treat user-generated content that is uploaded without monetary payment as part of a barter transaction in which ~~the~~ platform user receives unpriced platform services in exchange for the user-generated content. Under this alternative approach, the platform's unpriced services are used by the content creators as inputs to produce the user-generated content and the user-generated content is used by the platform to produce data assets. The net effect is to increase in the measure of the platforms' own-account investment in data assets.

## Chapter 23: Globalization (Chapter 15 BPM7)

*Note: This draft chapter has been prepared jointly to cover the full range of topics to be included in the BPM7 and 2025 SNA chapters on globalization. Only those issues that are relevant to external sector statistics will be included in BPM7; likewise, only those issues that are relevant to national accounts will be included in the 2025 SNA.*

### A. Introduction

- 23.1 Globalization refers to the economic integration of economies around the world. Reduced trade barriers and advancements in communication, transportation, and technology have facilitated a rise in the cross-border movements of goods, services, capital, information, and people in recent decades. Those factors have also contributed to increasingly complex corporate structures that span across multiple economies. Such multinational enterprise (MNE) groups can be set up for many reasons, including to reduce labor costs, transportation costs, taxes, and proximity to markets. In addition, other global manufacturing and distribution arrangements, such as factoryless goods production and merchanting, have added to the complexities of interrelations between economies. These globalization [development activities](#) pose challenges to traditional macroeconomic statistics, which are based on the concepts of residence and economic presence.
- 23.2 This thematic chapter is designed to elaborate on issues related to globalization that are touched upon throughout the Manual/SNA. It focuses on the conceptual, measurement, and analytical challenges that arise from deeper corporate linkages and the fragmentation of production processes across economies. These challenges motivate additional breakdowns and supplementary presentations, which provide alternative views or additional details that complement traditional macroeconomic statistics and are vital for better understanding the connections between economies.
- 23.3 To address the statistical challenges related to globalization, it is important to implement harmonized methodological guidelines to foster comprehensive data collection and international comparability. Even if headwinds develop to some of the factors driving globalization, the guidance in this chapter will still yield macroeconomic statistics that provide insights into the changing nature of globalization.
- 23.4 This chapter is organized as follows. Section B describes global production arrangements, while Section C defines MNE groups and discusses their role in globalization. Section D presents some of the measurement challenges related to MNE groups and global production. Section E introduces existing macroeconomic indicators, additional breakdowns, and alternative presentations that can help address these challenges and meet user needs. Finally, Section F describes analytical tools that have been developed to better understand the relationship between globalization and the domestic economy, including trade in value added and global value chains.

### B. Global Production

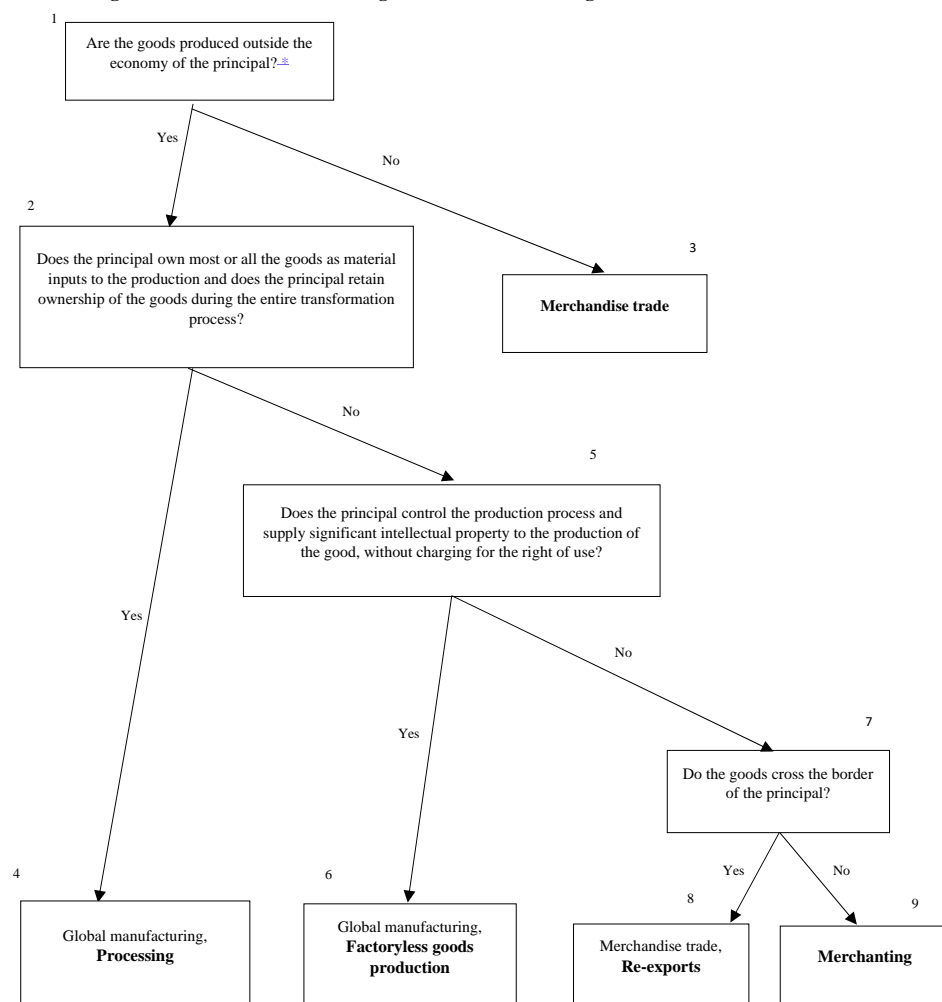

- 23.5 A distinct aspect of globalization is the fragmentation of production in production chains between resident and nonresident firms—the basis of global value chains (GVCs). GVCs are a fundamental pillar of the modern global economy, enabling companies to take advantage of global specialization, cost efficiencies, comparative advantages, and market opportunities. See paragraph [23.43112] for more details about GVCs.

#### 1. Global Manufacturing and Distribution Arrangements

- 23.6 Global manufacturing and distribution arrangements can be broken into different types. Figure [23.1] presents a decision tree to identify whether a transaction in a global arrangement is traditional merchandise trade, re-exports, merchanting, processing, or factoryless goods production. These arrangements are described below, and examples are provided in Box [23.1].

**Commented [ED1]:** This subsection will not be included in the BPM7 version of the chapter, but in BPM7 Chapter 10 on the Goods Account.

**Figure 23.1. Global manufacturing and distribution arrangements decision tree**

Notes: The decision tree is from the point of view of the principal enterprise that organizes or arranges the manufacture and/or movement of goods and has ownership of the goods at some stage. [Principals may engage in several types of production arrangements that may also involve a combination of domestic and foreign production.](#)

### Re-exports

23.7 *Re-exports are goods produced in other economies, and previously imported, that are exported with no substantial transformation from the state in which they were previously imported [insert reference to 2025*

SNA Chapter 33]. The price of the re-exported good may differ from its price at the time it was originally imported, due to factors such as transport costs, dealer's margins, and holding gains or losses. For goods to be included as re-exports, a resident must acquire and subsequently resell the goods with the goods passing through the territory. Goods that are bought and resold but do not pass through the territory of the unit initially purchasing the goods are included in goods under merchanting—see paragraph [23.XX12]. By convention, goods which are imported from a contractor and subsequently exported to a final buyer by a factoryless goods producer are not treated as re-exports, even if the goods pass through the economy of the factoryless goods producer. Instead, these goods are recorded as goods traded within a global manufacturing arrangement.

- 23.8 Goods in transit are not recorded in imports or in re-exports—instead, they are excluded from the general merchandise of the territory of transit. Also, goods cleared by customs, but re-exported without coming into ownership by a resident of that economy, should not be included in re-exports. In contrast to re-exports, in the case of returned goods, there is no change of ownership or the parties later agree to annul the change of ownership.
- 23.9 In cases where the state of the imported goods is substantially transformed, which could be indicated by a change in the Harmonized System (HS) code, goods are recorded as domestically produced exports rather than re-exports (e.g., goods that have been assembled or processed, or goods that have become rags, waste, scrap, or antiques). Used goods that were previously imported and retain the same HS code, but have suffered wear and tear, could in most cases be included in re-exports depending on the rules of origin that the economy applies. Whereas international recommendations<sup>1</sup> on rules of origin exist, the origin of the goods will be determined at a national level. The case of imported goods processed without change of ownership is discussed in paragraphs [23.21 – 23.27]. Goods temporarily imported or re-exported without a change of ownership, such as for repair or operating lease, are not included.
- 23.10 Where possible, re-exports should be shown separately as a supplementary item, particularly in economies where re-exports are a significant proportion of exports. Because re-exported goods are not produced in the economy concerned, they have less connection to the economy than other exports. Economies that are major transshipment points and locations of wholesalers often have large values of re-exports. It may be of interest to derive the value of imports destined for re-export, calculated from re-exports with any timing adjustment.
- 23.11 *Re-imports are domestic goods imported in the same state as previously exported, without any substantial transformation occurring on the goods while they were outside the territory.* [\[insert reference to 2025 SNA Chapter 33\]](#). Where significant, re-imports may be shown separately. Re-imports tend to arise in order to reverse a previous export, while re-exports generally arise because of transport, storage, or distribution through a territory other than that of the buyer or seller. For the goods to be included in re-imports, a nonresident must have acquired the goods, then resell them to a resident with the goods leaving and reentering the territory. (In cases where there was no change of ownership, they are omitted from imports, e.g., goods for repair or goods sent for processing.)

### **Merchanting**

- 23.12 *Merchanting is defined as the purchase of goods by a resident (of the compiling economy) from a nonresident combined with the subsequent resale of the same goods to another nonresident without the goods being physically moved in and out of the compiling economy.* Merchanting occurs for transactions involving goods where physical possession of the goods by the owner is unnecessary for the process to occur.
- 23.13 Inverse merchanting is a special case of merchanting, occurring when both the entity that is selling to the nonresident merchant and the entity that is subsequently purchasing from the nonresident merchant are both resident in the same economy (the compiling economy) and where the goods do not leave and re-enter the compiling economy. Because there is no physical cross-border flow to or from the compiling economy, it may be challenging to identify inverse merchanting from traditional merchandise trade data sources such as customs declarations. However, the goods account of the compiling economy should reflect that a change of economic ownership happens twice, first, as export of general merchandise when the goods are sold to the nonresident merchant and second, as import of general merchandise when the goods are subsequently

<sup>1</sup> World Customs Organization, *International Convention on the Simplification and Harmonization of Customs Procedures (Revised Kyoto Convention)*.

purchased from the nonresident merchant, and appropriate adjustments should be made if international merchandise trade statistics (IMTS) flows are used as a source.

23.14 The treatment of merchanting is as follows:

- a. The acquisition of goods by merchants is shown under goods [acquired under merchanting](#) as a negative export of the economy of the merchant;
- b. The sale of goods by merchants is shown under goods sold under merchanting as a positive export of the economy of the merchant;
- c. The difference between sales over purchases of goods for merchanting is shown as the item “net exports of goods under merchanting.” This item includes merchants’ margins, holding gains and losses, and changes in inventories of goods under merchanting. As a result of losses or increases in inventories, net exports of goods under merchanting may be negative in some cases;<sup>2</sup> and
- d. Because the change of ownership differs from the physical flow of goods, merchanting entries are valued at transaction prices as agreed by the parties, not free on board (FOB).

23.15 The partner allocation of net exports of goods under merchanting should be done by adding the positive and negative entries of goods under merchanting for each partner economy.

23.16 The rationale for recording goods under merchanting in the goods account and for treating purchases of goods for merchanting as a negative export rather than an import is as follows: firstly, the merchant acts similar to a wholesaler or a retailer whose output is measured by the trade margin realized on the goods they purchase for resale; next, the treatment of the net exports as goods rather than services maintains a global trade in goods balance; and finally, if the amounts of imports and exports of the merchant were recorded gross, this would artificially inflate the merchandise trade in the economy of the merchant.

23.17 The merchanting label is only used in the accounts of the economy in which the merchant is resident. In the counterpart exporting and importing economies, export sales to merchants and import purchases from merchants are included under general merchandise. Goods under merchanting are shown separately in statistics of the economy of the merchant because they are of interest in their own right and because they are not covered by the customs system of that economy.

23.18 Wholesaling, retailing, commodity dealing, and management of manufacturing may also be carried out under arrangements where the goods are present in the economy of the owner, in which case they are recorded as general merchandise, rather than as merchanting.

23.19 When a merchant resells goods to a resident of the same economy as the merchant, this does not meet the definition of merchanting. Accordingly, the purchase of goods is shown as imports of general merchandise to the economy in that case. If the entity that purchased from a merchant in the same economy subsequently resells the goods to a resident of another economy, whether or not the goods enter the economy of the merchant, the sales of goods are recorded in exports of general merchandise from the economy of the merchant and the entity that purchased the good from the merchant. (Although such a case is very similar to merchanting, it does not meet the definition given above. In addition, it is impractical for the first merchant to record the purchases as merchanting because that merchant may not know whether or not the second merchant will bring the goods into the economy.)

23.20 Sometimes a purchaser may be uncertain whether the goods will be resold to residents of the same economy or others. In this case, intentions can be used as an indicator, with subsequent adjustment if intentions are not realized.

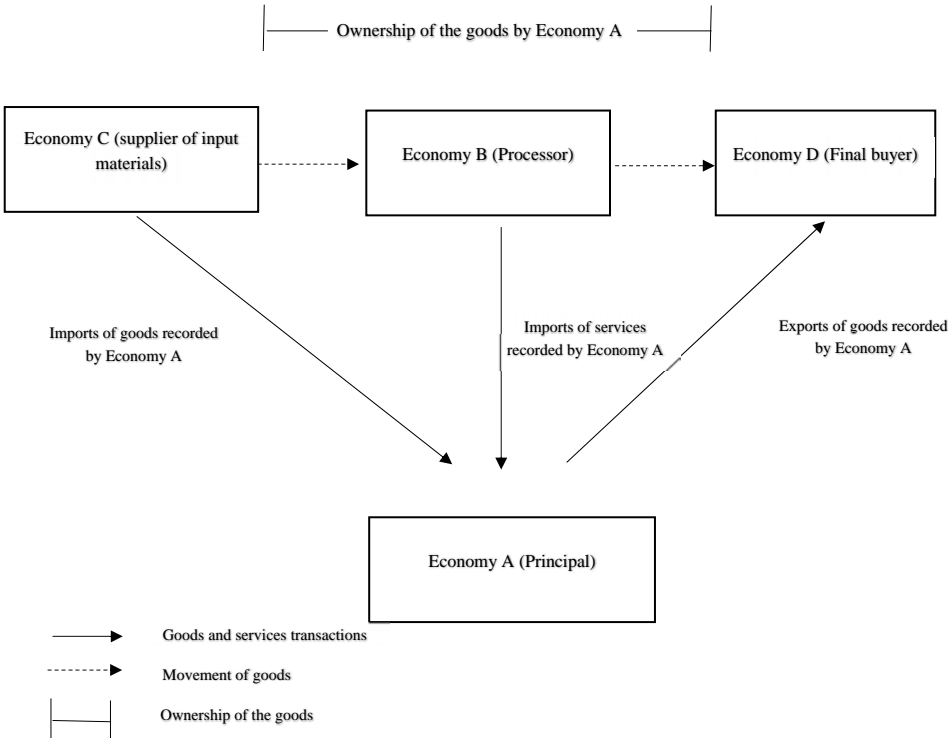

## Processing

23.21 Under a processing arrangement, the principal owns or acquires material inputs and purchases manufacturing services from a nonresident processor (who may provide some material inputs), to substantially change the goods. The ownership of the processed goods does not change during the manufacturing process. The finished

<sup>2</sup> When compiling statistics by partner economy for goods under merchanting, it is common to see negative net exports for partner economies from which the merchant acquires goods.

goods are then returned to the principal, sent elsewhere for further processing, or dispatched to final customers. In the simplest scenario, goods are ~~sent~~ physically ~~sent~~ abroad from the economy of the principal to the economy of the processor and returned after processing. In this case, the movement of the goods are recorded in the IMTS of both economies, but no general merchandise transactions would be recorded. Figure [23.2] illustrates a more complex example of a processing arrangement.

**Figure 23.2. Goods for processing arrangement**

Notes: The principal in Economy A purchases material inputs from Economy C. The goods are shipped to Economy B for further processing. The final goods are sold to Economy D. The principal has ownership of the goods during the processing, but the goods may not pass through Economy A during the production process.

There are variations of processing arrangements. Material inputs may also be sourced from Economy A, Economy B or Economy D. Similarly, the final goods may be sold to Economy A, Economy B or Economy C. The key aspect in all variations is that the processor in Economy B does not take ownership of the goods during the processing. In all variations, the physical flow of goods differs from the change of ownership to some extent.

- 23.22 Goods transactions between the principal in a processing arrangement and other parties may be shown as a supplementary sub-item of general merchandise.
- 23.23 In some cases, the processor provides other materials that are used in the manufacturing process alongside the material inputs owned by the principal. Other materials provided by the processor are treated as intermediate consumption of the processor. In many cases, the principal supplies inputs of intellectual property such as product design without charging the processor for the right to use.

- 23.24 As there is no change of ownership of the processed goods between the processor and the economy from which the goods have arrived or between the processor and the economy to which the goods are dispatched, no general merchandise transactions are recorded by the processor.
- 23.25 Purchases of material inputs (i.e., goods to be processed) by the principal in a processing arrangement may be obtained from residents of the same economy as the principal, the same economy as the processor, or a third economy. The treatment is as follows:
- when the goods are acquired from residents of the same economy as the principal, there is no international transaction; and
  - when the goods are acquired from residents of the same economy as the processor or a third economy, the principal records imports of general merchandise.
- 23.26 Sales of finished goods (i.e., goods after processing) are treated as follows:
- when the goods are sold to residents of the same economy as the principal, there is no international transaction; and
  - when the goods are sold to residents of the same economy as the processor or a third economy, the principal records the sale as exports of general merchandise.

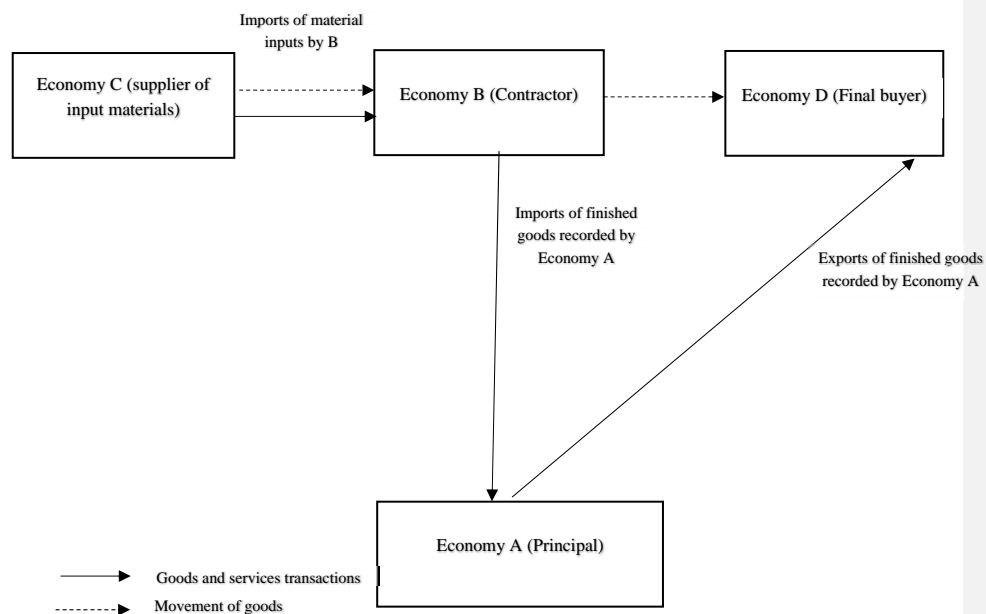

The principal could report merchanting in the case of minor processing (see paragraph [23.XX12] and the decision tree in Figure [23.1]).

- 23.27 The processing fee that the processor charges the principal under a processing arrangement should not be recorded under general merchandise but as a service [under manufacturing services on physical inputs owned by others](#).

### **Factoryless Goods Production**

- 23.28 A *factoryless goods producer* is a principal that controls the production of a good by undertaking the entrepreneurial steps and providing the technical specifications required to produce the good, but that fully outsources the material transformation process required to produce the output. The factoryless goods producer supplies inputs of intellectual property such as product design, without charging for the right to use the intellectual property, but outsources both the acquisition of all of the material inputs and the manufacturing process to a, usually nonresident, contractor. The factoryless goods producer buys the finished goods from the contractor at a price that includes the value of material inputs and processing but does not include the value of intellectual property used in the transformation process. The finished goods may be used by the principal as inputs into further production, sent elsewhere for further processing, or dispatched to final customers. Figure [23.3] illustrates one example of a factoryless goods producer arrangement.

**Figure 23.3. Factoryless goods producer arrangement**

Notes: The principal in Economy A supplies the design specifications but outsources the acquisition of the material inputs and the manufacturing to a contractor in Economy B. The contractor acquires the material inputs from Economy C. The contractor sells the finished goods to the principal at a price that includes the cost of the material inputs plus the manufacturing costs. The goods are then sold to the final buyer in Economy D at a price that will further reflect the input of the design specification by the principal. The final goods may be shipped directly from Economy B to Economy D without passing through Economy A.

There are variations of factoryless goods production. Material inputs may also be sourced from Economy A, Economy B, or Economy D. Furthermore, the principal may source the material inputs and sell them via merchanting to the contractor. The key aspect is that the contractor takes ownership of the material inputs. Finished goods may also be sold to Economy A, Economy B, or Economy C.

- 23.29 Transactions between the factoryless goods producer and other parties may be shown as a supplementary sub-item of general merchandise.
- 23.30 Under factoryless goods production, the material inputs are substantially transformed by the contractor. The inputs of intellectual property products into the transformation of the product retained by the factoryless goods producer should also be significant. As a general guideline, the input values of intellectual property products such as of research and development, design, innovation, and other marketing assets (trademarks, brand names, logos, etc.) supplied by the factoryless goods producer will be greater than the fee paid to the contractor excluding the material inputs.
- 23.31 The goods that the factoryless goods producer buys from the contractor are recorded as general merchandise imports at the value agreed between the principal and the contractor. These goods are considered inputs to the production of the factoryless goods producer.
- 23.32 Sales of finished goods are treated as follows:
  - a. when the goods are sold to residents of the same economy as the factoryless goods producer, there is no international transaction but a domestic transaction to show the sale of the goods to final

[consumer in the resident economy](#); and

- b. when the goods are sold to residents of the same economy as the contractor or a third economy, the factoryless goods producer records the sale as exports of general merchandise.

## Box 23.1. Examples of Global Manufacturing and Distribution Arrangements

### Example 1—Re-exports

A seaport in Economy A serves as a gateway hub for international trade for economies in the region. One practice is for car dealerships to set up near the port. Individuals can travel to the seaport and buy new and secondhand cars directly from the dealer in Economy A.

A car dealer of Economy A imports a car from Economy C for 1000. A resident of Economy B travels to the seaport and buys the car for 1200, driving home through Economy A to Economy B.

Since the goods are imported and subsequently exported, with a change of ownership happening twice in Economy A, and the goods pass through Economy A, the goods are recorded gross in the imports and exports of [Economy A](#) as follows:

General merchandise imports (from Economy C)	1000 Expenditure
General merchandise exports (to Economy B)	1200 Revenue
Of which: Re-exports	1200 Revenue

(As the goods are in excess of customs thresholds in this example, they are included in general merchandise rather than in travel).

### Example 2—Merchanting with manufacturing services that do not change the condition of the goods

A resident of Economy A acquires books from a resident of Economy C for 10. The resident of Economy A has them sent to Economy B, without the books passing physically through Economy A, for a resident of Economy B to put in boxes, for a charge of 3 payable by the resident of Economy A. The books are then sold by the resident of Economy A to a resident of Economy D for 20.

Since the goods are in the same condition, the merchanting treatment applies. The goods and services account entries for Economy A would be:

Goods acquired under merchanting (from Economy C)	–10 Revenue (negative exports)
Goods sold under merchanting (to Economy D)	20 Revenue
Net exports of goods under merchanting	10 Revenue
<a href="#">Manufacturing</a> Import of manufacturing services on physical inputs owned by others ( <a href="#">with</a> from Economy B)	3 Expenditure

(Economy C records goods exports of 10 to Economy A under general merchandise; Economy B records services exports of 3 with Economy A; and Economy D records goods imports of 20 under general merchandise with Economy A.)

### Example 3—Processing arrangement: Manufacturing services that change the condition of the goods

A resident of Economy A (the principal) acquires oil from a resident of Economy C for 10. The oil is sent to Economy B, without passing through Economy A, for refining by a resident of Economy B, for a charge of 15; the oil continues to be owned by the resident of Economy A. ~~The oil~~[The refined product, for instance fuel](#), is then sold to a resident of Economy D for 30.

Since the goods are not in the same condition, the merchanting concept does not apply. The goods account and services account entries for Economy A would be:

*General merchandise import (from Economy C)	10 Expenditure
*General merchandise export (to Economy D)	30 Revenue
Import of manufacturing services on physical inputs owned by others (from Economy B)	15 Expenditure

Economy C records goods exports of 10 to Economy A (~~10 Expenditure~~). Economy B records only manufacturing services on physical inputs owned by others exports of 15 to Economy A (not exports or imports of goods), and as noted above, Economy D records goods imports of 30 from Economy A under general merchandise (not goods imports from Economy B).

Economy B may wish to identify the values of material inputs received and goods sent abroad after processing as supplementary items.

**Example 4—Factoryless goods production**

A resident of Economy A (the principal, or factoryless goods producer) contracts the production of sportswear to a manufacturer in Economy B. The contractor in Economy B purchases the material inputs from Economy C for 3. The transformation of the material inputs by the contractor in Economy B is done under specifications provided by the principal. The principal purchases the finished sportswear from the contractor for 7 (which was agreed as part of the contracting arrangement), and resells these goods directly to the final buyer in Economy D for 28 without the goods passing through Economy A.

The goods account entries for Economy A would be:	
*General merchandise imports (from Economy B)	7 Expenditure
*General merchandise exports (to Economy D)	28 Revenue
The goods account entries for Economy B would be:	
General merchandise imports (from Economy C)	3 Expenditure
General merchandise exports (to Economy A)	7 Revenue

Economy C and Economy D should record the counterpart transactions with Economy A and Economy B. No trade is recorded between Economy B and Economy D.

**Example 5—Factoryless goods production with material inputs acquired and resold under merchanting by the principal to the contractor**

A resident of Economy A (the principal, or factoryless goods producer) contracts the production of sportswear to a manufacturer in Economy B. The principal sources the material inputs from Economy C for 3 and resells the material inputs to the contractor in Economy B for 4, without the goods passing through ~~economy~~Economy A. As in Example 4, the transformation of the material inputs by the contractor in Economy B is done under specifications provided by the principal. The principal purchases the finished goods from the contractor for 8, and resells these goods to the final buyer in Economy D for 28 without the goods passing through Economy A.

The goods account entries for Economy A would be:	
*Goods <u>acquired</u> under merchanting ( <del>with</del> <u>from</u> Economy C)	-3 Revenue (negative exports)
*Goods <u>sold</u> under merchanting ( <del>with</del> <u>to</u> Economy B)	4 Revenue
Net exports of goods under merchanting	1 Revenue
*General merchandise imports (from Economy B)	8 Expenditure
*General merchandise exports (to Economy D)	28 Revenue

Economy C records goods exports of 3 to Economy A; Economy B records goods imports of 4 and goods exports of 8 with Economy A; and Economy D records goods imports of 28 with Economy A.

\* Items marked with an asterisk are recommended to be shown separately as supplementary items for recording global production arrangements of Economy A (see paragraphs [23.XX14, 23.22, and 23.XX29]).

## C. Multinational Enterprise (MNE) Groups

References:

International Monetary Fund (IMF), *Special Purpose Entities: Guidelines for a Data Template*

Organization for Economic Cooperation and Development (OECD), *OECD Benchmark Definition of Foreign Direct Investment*

United Nations Economic Commission for Europe (UNECE), *UNECE Guide to Measuring Global Production*

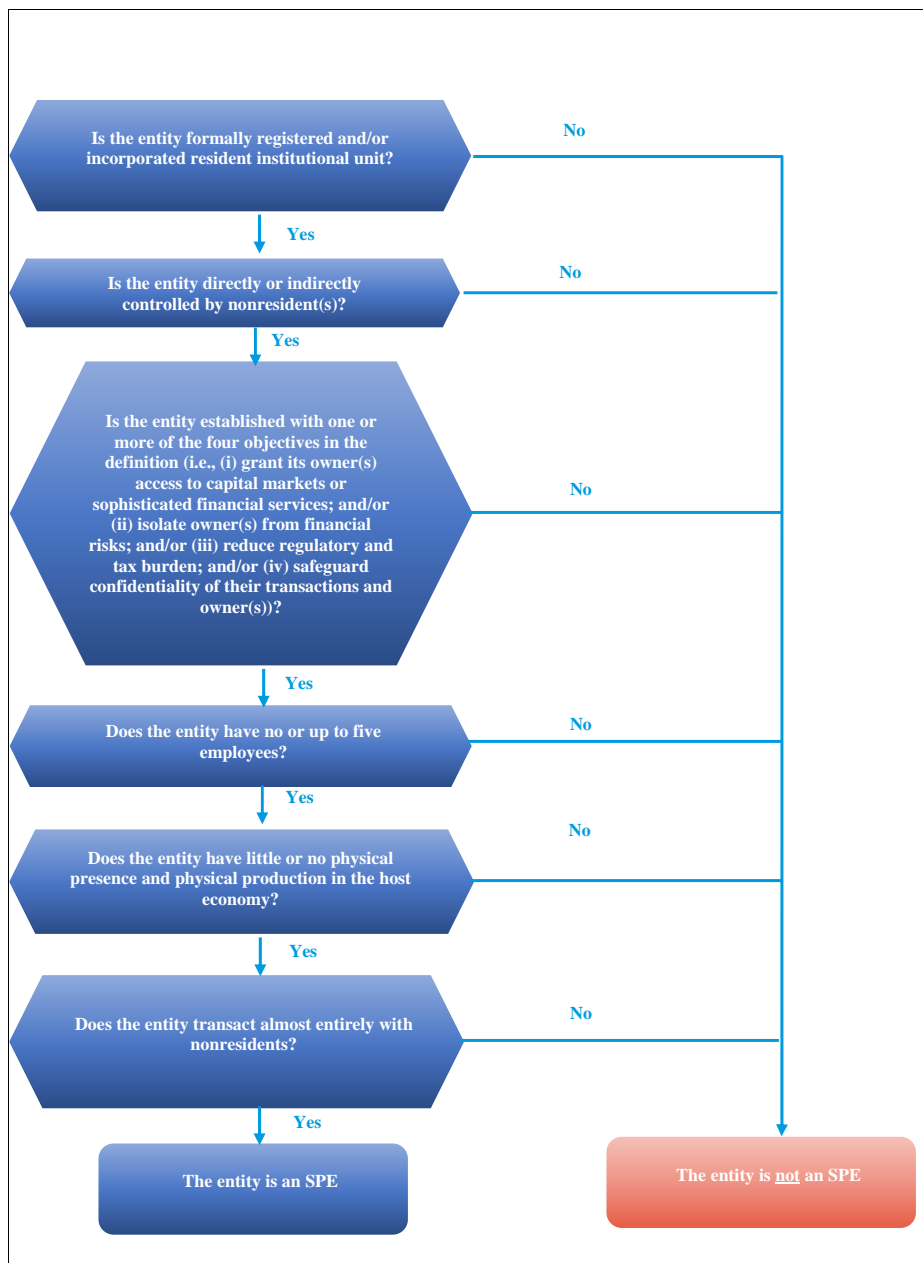

### 1. Definition of MNEs, MNE Groups, and Concept of Control

- 23.33 An MNE is a legal entity that has at least one nonresident affiliate or branch, and exercises control over its affiliate(s) or branch(es) either directly—by owning over 50 percent of the voting power in the entity—or by indirect transmission of control. The MNE is the ultimate controlling parent—the direct investor at the top of the control chain. The MNE group consists of the MNE and the set of entities—regardless of their economies of residence—that are under the control of the same ultimate controlling parent [insert reference to relevant paragraph in *BPM7* Chapter 4/2025 *SNA* Chapter 5].
- 23.34 Control refers to the ability to determine general corporate policy of a corporation. In practice, control is determined to exist if an investor has more than 50 percent of the voting power in an enterprise. The control may be direct (through ownership of voting power or other arrangements) or indirect (through ownership of enterprises that in turn have voting power). This definition of control is aligned with the Framework of Direct Investment Relationship (FDIR), which is a generalized methodology for identifying and determining the types and extent of direct investment relationships [insert references to *BPM7* Chapter 6 and *OECD Benchmark Definition of Foreign Direct Investment*].
- 23.35 It is important to distinguish between ownership and voting power when determining control. While ownership shares and voting power generally are aligned, this is not always the case. For instance, voting power may be greater or less than the percentage of shares held when there are “golden shares” or dual classes of shares, i.e., in cases in which nonvoting shares or some shares have higher weights that allow one or more parties to exercise voting power disproportionately to their share ownership [insert reference to *BPM7* Chapter 6]. Control by government, or another public unit, can also be exercised in other ways than owning more than half of the voting power.

### 2. Understanding the Role of Special Purpose Entities (SPEs) within MNE Groups

- 23.36 Through their activities, MNEs manage production, trade, financial services and intermediation, direct investment, and international transfer of knowledge and technology, with the aim of maximizing their global after-tax profits. MNEs often have significant impact on the real economy through their activities, but they sometimes set up entities with limited presence in the form of employment and physical production to benefit from different regulatory and tax regimes. Special purpose entities (SPEs) are specific cases of such entities and are defined in Chapter 4/5 [insert reference to relevant paragraphs when available]. The decision tree in Figure 23.4 can also be used to identify SPEs.

**Figure 23.4. Decision Tree to Identify Resident SPEs**

- 23.37 Although SPEs have no or little physical presence, they can have a substantial impact on traditional macroeconomic statistics—for example, inflating (foreign) direct investment statistics due to pass-through funds or data for services exports if they own IPPs. Host jurisdictions are encouraged to report supplementary data for SPEs, particularly when such entities are significant [insert references to relevant paragraphs in *BPM7/2025 SNA*].
- 23.38 A typology of SPEs is presented in Table [23.1]. It can be used to identify SPEs and to determine their appropriate institutional sector. The typology aims to delineate the different types of SPEs based on their economic functions and relate them to their institutional sector.
- 23.39 The typology should be used as a complement to the definition of SPEs as it is not meant to be either exhaustive or prescriptive. The entities covered by the typology may be SPEs, but not all entities of the types listed are classified as SPEs. For instance, SPEs may include securitization vehicles, but not all securitization vehicles meet the definition of SPEs. A securitization vehicle would, for example, not be classified as an SPE if it has significant transactions with residents.

**Table 23.1. Typology of SPEs** [*The table will be updated to include 2025 SNA and BPM7 references in due course*]

No	SPE Type	Description	2008 SNA	BPM6	2008 SNA sector
<b>Category I: Corporate Groups' Captive Financial Entities</b>					
<i>(Those captive entities created by a financial or nonfinancial nonresident corporate to fulfil specific financial activities, other than insurance, for the sponsor)</i>					
1.1	Conduits	Raising or borrowing funds, often from unrelated enterprises, and remitting those funds to its parent or to another related enterprise. Typically, do not transact on the open markets on the asset side.	Para 4.59	Para 4.51 Para 4.86	S127
1.2	Holding companies	Owning a controlling level of equity in subsidiaries, without actively directing them (Passive holding corporations)	Para 4.59	Para 4.51 Para 4.84	S127
1.3	Holding financial assets for securitization			Para 4.51	S127
1.4	Intra group lending companies	Loan funding from and to intra group companies Entities taking and granting inter-company loans		Para 4.51	S127
1.5	Captive factoring and invoicing companies	Concentrating sales claims and invoicing sales.			S127
1.6	Captive financial leasing companies	Engaging in lease-in lease-out agreements or as a financial intermediary in a chain of vehicles in which the end		Para 4.83	S127

No	SPE Type	Description	2008 SNA	BPM6	2008 SNA sector
		vehicle is involved in the leasing of equipment or fixed assets.			
1.7	Other captive financial companies	Dealing with financial needs of a group, such as financing particular projects and loan origination.		Para 4.87	S127
<b>Category II: Specialized Financial Entities</b> <i>(These financial entities, with a degree of operational autonomy, have been specially created to isolate the risks of the parent companies to structure financial transactions for or securitize assets of the parents)</i>					
2.1	Captive insurance companies	Providing insurance to group enterprises.		Para 4.88	S128
2.2	Securitization vehicles/Financial vehicle corporations	Carrying out securitization transactions in order to isolate the payment obligations of the undertaking from those of the originator, or the insurance or reinsurance undertaking (in the case of insurance-linked securitizations). <a href="#">Repackaging of existing financial assets.</a>	Para 4.59	Para 4.51 Para 4.77	S125
2.3	Holding financial and nonfinancial assets (including real estate) for related companies	Holding financial and nonfinancial assets of related companies with the goal of capital appreciation, interest/dividend income, and other income.			S11 and S125
2.4	Companies carrying out other financial functions	Performing factoring, invoicing on open markets, financial leasing on open markets, and other financial assets management.		Para 4.51 Para 4.76	S125
<b>Category III: Corporate Groups' Nonfinancial Entities</b> <i>(Those SPEs created by a financial or nonfinancial nonresident entity to fulfil specific nonfinancial activities)</i>					
3.1	Ancillary companies	Registered or incorporated companies providing ancillary services that are not resident in the same economy as its parent.		Para 4.51	S11
3.2	Operational leasing companies	Holding fixed assets, such as planes, vessels, and machinery, for the purpose of leasing them out.			S11
3.3	Merchanting companies	Purchasing goods from a nonresident and re-selling the goods to another nonresident (merchanting companies have ownership of the goods traded).			S11

No	SPE Type	Description	2008 SNA	BPM6	2008 SNA sector
3.4	Royalty and licensing companies	Concentrating group receipts concerning royalties and similar flows received from intellectual property rights and trademarks. Such a company of an SPE-type receiving royalties or similar flows for a group of enterprises or individuals is regarded as an independent royalty and licensing company.			S11
3.5	Legal ownership of intangible assets	Holding intangible assets for a related company or group of companies.			S11
<b>Category IV: Wealth management entities</b> <i>(Those SPEs created by household entities or groups of individuals to hold or manage wealth or real estates for their owners)</i>					
4.1	Companies holding/managing wealth and real estate for individuals and families	Managing family trust funds, foundations, personal holding companies.	Para 4.59	Para 4.51	S11, S126, and S127
<b>Category V: Government Owned Financial Entities</b> <i>(Those SPEs created by governments for fiscal activities)</i>					
5.1	SPEs owned by governments for fiscal purposes	Raising or borrowing funds on behalf of a nonresident general government.		Para 8.24	S11, S12, or S15
<b>Category VI: Other structures</b> <i>(Those SPEs created to conduct any type of transactions other than those covered in the other categories)</i>					

Note: The entity types listed may be SPEs, but not all entities of the types listed are necessarily SPEs. The SPE definition and decision tree should assist compilers in determining which entities are SPEs.

### 3. MNEs, SPEs, and Intellectual Property Products (IPPs)

- 23.40 MNEs often manage intellectual property products (IPPs), which are defined and described in further detail in Chapter 11 [insert reference to relevant paragraphs in *BPM7* Chapter 11/2025 *SNA* Chapter 11]. MNEs increasingly establish SPEs not only to channel financial investments, but also to manage IPPs.
- 23.41 The intangible nature of IPPs makes the transfer and use of IPPs difficult to observe. Especially for IPP transactions within an MNE group, this nonphysical feature can cause significant measurement difficulties. The main difficulty relates to identifying economic ownership (as opposed to legal ownership), which has repercussions for the treatment of related flows, namely those related to IPP use.<sup>3</sup>

<sup>3</sup> The following paragraphs on determining economic ownership of an IPP observed in global production are based on Chapter 4 of the *UNECE Guide to Measuring Global Production* where additional information can be found.

23.42 Figure [23.5] shows a decision tree which assists in determining the economic ownership of IPPs and IPP-related transactions (including IPP-related import and export flows). The tree represents a sequence of steps, from left to right, guiding the statistics compiler to a decision. The starting point of the tree is the observation of IPP output or IPP ownership at the level of a certain unit. The obtained information is examined in 4 different steps:

- a. Control/ownership of the unit: ~~Is~~Does the unit participate in a global production arrangement as member of an MNE group?
- b. ~~Is~~Did the unit ~~the producer of~~produce the IPP?
- c. What is the main kind of activity of the unit, or is the unit expected to use the IPP in its production process?
- d. Does the unit receive ~~income~~revenue related to IPPs, or does the unit pay for the use of IPPs (royalties and licenses)?

23.43 Together these steps should lead to a coherent decision on ownership, the recording of capital formation and the recording of IPP-related service flows (including imports/exports). However, it should be acknowledged that the availability of information needed to go through each of these steps may be insufficient. Particularly inside MNE groups, it may be quite challenging to classify IPP-related transactions properly, identifying separately IPP funding, IPP purchases, and sales and payments for IPP use. This means that each situation identified in the decision tree will be provided with a default solution in case information is insufficient to run properly through each of the decisive steps.

23.44 The first part of the decision tree describes the situation of units inside MNE groups. ~~The~~In cases where the unit produced the IPP, the observed unit may be a main producer of goods and non-IPP services (1.1.1) or a main IPP producer (1.1.2) serving the IPP needs of the various members of the MNE group. In the case of a main producer of goods and non-IPP services, the (default) decision is to assign economic ownership to the unit in question. It could be that other units inside the MNE group equally benefit from this IPP. However, in such cases, it is recommended that intra-group transactions are only recorded when data sources point at receipts for IPP use by member units.

23.45 In case of a main IPP producer, economic ownership of the produced IPP is assigned to this unit (1.1.2.2) unless there is evidence the unit does not generate any IPP-related turnover (e.g., sales of copies, licences to use), or there is evidence of sales of the original to the parent or to other customers (1.1.2.1). No observed IPP-related turnover implies the unit is indirectly funded by the parent. Without conclusive evidence, the default solution is to assign economic ownership to the producing unit (1.1.2.2).

23.46 Source statistics may indicate the use or ownership of IPPs, but without the observed unit being identified as the producer of IPPs (1.2). Unless there is evidence of purchases of IPP originals, such units will generally not be considered the economic owners of IPPs. One may expect that payments for IPP use will be observed (1.2.1.1). But even without such payments, it is quite possible that these units use IPPs provided by the MNE parent in their production processes (1.2.1.3).

23.47 However, one could also argue that since these units are obtaining the benefits from IPPs, they could alternatively be identified as the actual economic owners inside MNEs. This would require imputing the transfer of the IPP original from the parent to the unit and capitalization of this IPP on the balance sheet of the unit under observation. This is not an easy task, and not without risks. The nature, size, and timing of these flows are principally unknown. This is why such an approach is not recommended under 1.2.1.3.

23.48 Case 1.2.2 reflects those units created by MNEs with the purpose of taking advantage of low-tax jurisdictions. The default solution is assigning economic ownership of the IPP to these units, in correspondence with legal ownership. ~~Rerouting of~~Reassigning economic ownership, and corresponding ~~income~~revenue flows, from the legal ~~to the economic~~ owner to some other unit is not recommended. However, ~~income~~revenue received by these ~~units~~legal owners should preferably be ~~classified under~~shown as an "of which" item with a separate heading such as "IPP-related services provided by SPEs", as the provision of these services by SPEs is likely to have very little impact on employment and physical economic activity in the domestic economy. A separate reporting of these IPP services will provide a clearer view on national accounts and balance of payment

statistics.

- 23.49 The second part of the decision tree (2) reflects the situation of global production in which a principal ~~that does and a manufacturer with which it contracts are not belong to an part of a common~~ MNE group ~~contracts with a manufacturer~~. In appraising IPP ownership under such conditions, there are typically two situations to consider. In the first situation (2.1.1), the manufacturer owns the IPP and uses it in its production process, which implies the principal is simply obtaining a full-fledged product including the IPP service. In this case, there is no necessity of recording IPP transfers. The principal has no involvement in the manufacturing process and is expected to concentrate its business on trade-related activities. The IPP recording aspects are relatively straightforward: the manufacturer in question invests on own account in IPP and the asset value should be recorded in its balance sheet.
- 23.50 In the second situation, the principal owns the IPP and provides a contractor with its blueprints of the required output (2.1.2). No IPPs, or IPP-related transactions, will need to be identified when observing the contractor's production activities. The contractor will deliver a product to the principal; however, without reflecting the user costs of the IPP.
- 23.51 The decision tree also reflects the (perhaps hypothetical) situation in which the factoryless producer puts into use the IPPs developed by others (2.2.2.2). Such units will be IPP owners when they purchased the IPP originals. Alternatively, they could use the IPPs owned by dedicated IPP producers.
- 23.52 Outside the scope of MNEs, IPP-related transactions may be observed when dedicated producers provide IPP originals or IPP-related services (2.1.2.1) to those entities in the production chain engaged in manufacturing (2.2.1).
- 23.53 In conclusion, when ~~there is a need to record~~ IPP-related transfers occur outside the domain of MNE groups, such transfers are usually observed from market transactions, and this makes the recording much less complicated. Similarly, the identification of IPP ownership is usually more straightforward when the entities involved do not belong to the same MNE group.
- 23.54 Yet, the analysis of IPP use in production typically requires a complete picture of the global production chain, which will not be obtained from a national input-output table. Alternatively, a worldwide input-output table may show how IPPs are linked, for example via factoryless goods producers, to the global production chain.

**Figure 23.5. Decision tree for determining economic ownership of an IPP observed in global production**

Control/ownership of unit	Production of the IPP	Type of producer	Revenue and expenditure related to the IPP	Decision about economic ownership of the IPP	Related decisions
1.1 The unit produced the IPP		1.1.1. The unit is a main producer of other (non IPP) goods and services and is expected to use the IPP in its production process	1.1.1. The unit may, or may not, receive funding from the parent as compensation for IPP development costs but this aspect is not decisive.	Attribute by default economic ownership of the IPP to this unit	The IPP is by convention recorded on the balance sheet of this unit, even when other member units of the MNE may benefit from the IPP.
			1.1.2.1. The unit does not receive revenue from royalties or licences to use, but either receives compensation for IPP development from the parent or sells the IPP originals to the parent.	Do not attribute economic ownership to the unit. This unit serves as a dedicated IPP producer for the benefit of the MNE as a whole.	Do not record the IPP as fixed capital formation of the unit. Instead record the developed IPP as export to the (foreign) MNE parent. Reported sales of IPP originals may show up in international trade in services statistics.
		1.1.2. The unit is a main IPP producer.			

1. The unit participates in a global production arrangement as member of an MNE group		1.1.2.2. The unit receives revenue from royalties or licences to use, or does not receive any compensation for IPP development from the parent, so it can be assumed that it is expected to obtain revenue from royalties and licences to use in the near future.	Attribute economic ownership to the unit. The unit functions as a dedicated IPP producer with revenue from units outside the MNE from the IPPs produced.	The IPP is recorded as fixed capital formation of the unit.
1.2. The unit did not produce the IPP		1.2.1.1. The unit pays royalties or licences to use.	The unit does not own the IPP	Do not record the IPP as fixed capital formation of the unit. IPP service payments to foreign suppliers are recorded as import of IPP services (or royalties).
	1.2.1. The unit is a main producer of other (non IPP) goods and services and may use the IPP in production			
		1.2.1.2. The unit purchased the IPP original for use in production	Attribute economic ownership of the IPP to the unit	The IPP is fixed capital formation of the unit. If purchased from abroad register an import of the IPP (original)
		1.2.1.3. No IPP related payments are being observed. IPP use may be indirectly observed based on the nature of the production process (with usually high IPP requirements) and above average returns to capital.	The MNE parent is expected to be the economic owner and supplier of the IPPs used in production.	Conceptually, an imported IPP service flow should be recorded. But this is not an easy task (and not without risks) as the nature and size of these flows are principally unknown. Such imputations of imports/exports should preferably be the outcome of a concerted action in which all national statistical institutes (NSI) involved join efforts in filling in the IPP flows between the units of an MNE.
	1.2.2. The unit is not a producer of other (non IPP) goods and services. Its main output is IPP related.	1.2.2. Purchase of the IPP from the parent and revenue from royalties and licences to use may, or may not, be observed.	The unit is assumed to have purchased the IPP (original) from the parent and to receive (on behalf of the parent) revenue from royalties or licences to use the IPP. Attribute economic ownership of the IPP to the unit. The unit is considered an IPP holding SPE providing its services to the MNE parent.	It is recommended to classify the fixed capital formation, revenue and expenditure related to these IPP holding SPEs separately to allow analysis excluding "brass plate" units, also because the transactions carried by these units are not necessarily at arm's length.

<i>Control/ownership of unit</i>	<i>Production of the IPP</i>	<i>Type of producer</i>	<i>Revenue and expenditure related to the IPP</i>	<i>Decision about economic ownership of the IPP</i>	<i>Related decisions</i>
2. The unit participates in a global production arrangement but not as member of an MNE group	2.1. The unit produced the IPP	2.1.1. The unit is a producer of other (non IPP) goods and services and is assumed to use the IPP in production		Attribute economic ownership of the IPP to the unit	The IPP is fixed capital formation of the unit.
			2.1.2.1. The unit receives revenue from copies, royalties or licenses to use.	Attribute economic ownership of the IPP to the unit.	The IPP is fixed capital formation of the unit. If royalty payments are received from abroad register these payments as exports of IPP services.
		2.1.2. The unit is a main IPP (or factoryless goods) producer.			
			2.1.2.2. The unit does not receive revenue from copies, royalties or licenses to use the IPP. One may assume that this unit operates as a factoryless goods producer (FGP).	Attribute economic ownership of the IPP to the unit.	The IPP is fixed capital formation of the unit.
	2.2. The unit did not produce the IPP.		2.2.1.1. The unit pays royalties or licenses to use the IPP	The unit does not own the IPP	Don't include the IPP as fixed capital formation of the unit. If payments to abroad register imports of IPP services
		2.2.1. The unit is a main producer of other (non IPP) goods and services and is expected to use the IPP in production			
			2.2.1.2. The unit purchased the IPP.	Attribute economic ownership of the IPP to the unit.	The IPP is fixed capital formation of the unit. If purchased from abroad register imports of the IPP
			2.2.2.1. The unit receives revenue from royalties or licenses to use the IPP	Attribute economic ownership of the IPP to the unit	The IPP is fixed capital formation of the unit. If revenue is received from abroad register exports of IPP services
	2.2.2. The unit is a main IPP (or factoryless goods) producer.				
		2.2.2.2. The unit does not receive revenue from IPP related royalties or licenses to use. Instead, payments for IPP use (originals or copies) may be observed. This unit is expected to operate as an FGP.		The economic ownership of the IPP should be judged on the basis of the IPP related transactions observed with this unit. It is possible that the unit makes use of IPP services provided by dedicated IPP producers.	The IPP is fixed capital formation of the unit when the purchase of an original is observed. Otherwise, the unit is expected to purchase IPP services in which case royalty or license payments should be observed.

## D. Measurement Challenges

- 23.55 MNE and intra-MNE group flows present measurement challenges for the [SNA/Manual], which can lead to misinterpretation or, in some cases, even mismeasurement of the values in the accounts. The concepts of residence and economic presence, which are central to macroeconomic statistics, ~~are less important to assume a different relevance for~~ MNE groups, for which activities extend across national boundaries. This has increased the complexity of compiling national statistics, as it is more difficult to break down production by economy. The [SNA/Manual] treats foreign affiliates of MNEs as residents in their respective economies of operation. This treatment is designed to place production in the economy in which it occurs, which is fundamental for estimating the economy's GDP and other key balancing items. Furthermore, the existence of distorted transfer pricing on intra-group flows—when prices do not reflect the “arm's length” exchange values recommended by the [SNA/Manual]—or the practice of not recording transactions for the intra-group use of intellectual property products may result in the misallocation of production between the economy of the parent company and those of its affiliates (see also Section C). Moreover, in many cases, estimates recorded by MNEs in national statistical surveys may not be best suited to meet the purposes of national accounts and external sector statistics.
- 23.56 Although the extent of these issues is not easily quantified, the problems are significant because of the growing size and importance of MNE activities. Economic decisions made by MNEs can have a significant effect on macroeconomic statistics. When misinterpreted or mis-measured, these activities can adversely affect the quality of key macroeconomic indicators. The impact on GDP might result from the misallocation between statistics on international trade in goods and services relative to income and the depreciation charges associated with movable corporate assets, especially intangible assets. Consequently, without robustly accounting for MNE group activities, the reliability of macroeconomic statistics for policymaking purposes may be challenged.

### 1. Allocation of Activities to Different Economies

- 23.57 With complex global corporate structures and production arrangements dividing activities across many jurisdictions, there arises the issue of the subsequent allocation of these activities to different economies. MNEs are likely to try to maximize their enterprise-wide global after-tax profits rather than their profits in each of the economies in which they operate. Toward this end, they often structure the locations of their operations, the legal ownership of their assets, and the pricing of intra-enterprise transactions in ways that are designed to reduce their global tax liabilities or regulatory burdens. As a result, statistical measures based on MNEs' business records may be difficult to interpret and for certain types of analysis may even be considered to provide a distorted view of the value of the intra-enterprise transactions and the allocation of activities across economies.
- 23.58 MNEs can reduce their global taxes through a number of strategies, including using distorted transfer pricing between the parent and its affiliates or among the affiliates to shift ~~income~~ profits to lower tax economies; assigning or transferring ownership of IPPs or other movable assets across economies in a manner that reduces tax burdens; interposing a finance or holding company affiliate in a low-tax economy between themselves and their affiliates; establishing offshore factoring corporations in low-tax economies that bill and collect for the parent's worldwide sales; and inverting the corporate ownership structure, with an overseas affiliate in a low-tax jurisdiction becoming the parent that collects net income for the MNE's worldwide corporate structure. As explained in [chapter 4, section on transfer pricing], transfer prices may be distorted – that is, incompatible with the valuation principles used in the [SNA/Manual] – in which case they should be adjusted to actual ~~exchange values if it is practical to do so~~ market prices. However, because of all the complexities involved to arrive at a consistent recording of the adjustments, national accounts and external accounts often refrain from trying to approximate true market prices (see paragraph 4.160).
- 23.59 The use of finance or holding company affiliates, factoring corporations, and corporate inversions are not necessarily inconsistent with the principles used in the system, but they may lead to difficulties in compiling and reconciling the statistics and in interpreting the flows reported by the accounts. Complex financing and ownership structures of MNEs can mask ultimate ownership links and inflate (foreign) direct investment flows and positions as each flow into and out of each economy is counted even if the funds, or income, are just passing through. Compilers can provide additional breakdowns to show, for example, the effects of any

adjustments made to transfer prices (or of the potential effects of not being able to adjust transfer prices to exchange values) or of other factors that lead to multinational profits that are not reflected in measured income in the domestic economy. The macroeconomic indicators and supplementary information discussed in Section E of this chapter also help address misinterpretation of the accounts, including by distinguishing between domestically and foreign-controlled corporations.

## 2. Cross-Border Mobility of Corporate Assets

- 23.60 Cross-border mobility of movable corporate assets, including intangible assets such as IPPs, can make the true location of the generation of profits and value added ambiguous. Because intellectual property products are not physically constrained and the use of an IPP by one part of an MNE group does not prevent the simultaneous use by another part, the MNE can potentially register a previously produced IPP in another economy to maximize the MNE group's overall post-tax profits.
- 23.61 Determining economic ownership of IPPs potentially has a major effect on the recording of assets and related flows in macroeconomic statistics. The creation of IPP assets at one location in an MNE group is quite often funded by affiliates elsewhere in the group. These arrangements are known as cost sharing agreements where the costs associated with research at one location are funded by a number of affiliates across the group.
- 23.62 Section C of this chapter and Figure [23.5] describe the decision tree that should be used to determine the economic ownership of IPPs. It should be emphasized, however, that the measurement of the IPP-related flows within an MNE group, such as recording the sale or transfer of IPP assets or the payment of royalties based on reported transfer prices, could significantly bias the flows shown in the accounts relative to the discounted present value of expected future returns, which unfortunately may not always be available to the compiler. Also, if faulty data are used in implementing the decision tree for determining economic ownership, ownership of IPPs could be attributed to the wrong economy, which would lead to distortions in GDP and other macroeconomic indicators. Furthermore, even when the data underlying the determination of economic ownership and the measurement of IPP flows are correct, in some cases the resulting flows could be surprising to data users and might be inappropriate for certain types of analysis. For example, if a large MNE that produces software originals transfers the ownership of the originals to a low-tax economy, and the global sales of copies of the software are routed through the [low-tax](#) economy, ~~the~~[this](#) economy could show high value-added in software copies with very little associated employment of labour or remuneration of employees. Some users of the GDP statistics for that economy might consider the statistics to be distorted, or at least to be difficult to interpret in the context of typical business cycle analysis that assumes a strong relationship between GDP and aggregate employment. Moreover, the transfer of the originals themselves poses challenges to the interpretation of net exports and capital formation. If practical, the identification within exports/imports and capital formation of transfers of previously produced IPPs contributes to understanding the role of those transactions in GDP and components.

## 3. Consistency and Coherence of MNE Group Data

- 23.63 Ensuring that all activity of an MNE group is captured, not duplicated, and properly allocated by economic territory is a statistical challenge since the SNA/Manual standards do not view the MNE group as a single entity. If not properly recorded, the activities of MNE groups could result in a misallocation of GDP and, as a result, could distort an economy's macroeconomic indicators.
- 23.64 Inconsistent recording of some transactions of MNE groups can lead to large discrepancies in the accounts. Various data sources used in the compilation of statistics may use different statistical units or definitions and may record data in different ways, making it difficult for the compiler to achieve consistency in the measurement of economic activity. Compilers in some national statistical offices have addressed these issues by focusing attention on large MNEs, endeavoring to coordinate the collection of data from the MNE group, tracking changes in the composition of the group, and conducting coherence analysis to ensure that the data are consistent. The successful pursuit of this strategy requires monitoring and understanding of the business activities of the MNE group, as well as maintaining good communication with representatives of the group. In several countries, these tasks are carried out by specific statistical units, combining the expertise of national accountants, balance of payments experts, and business accountants. [Where confidentiality rules allow for it,](#)

[compilers are also encouraged to exchange data and reconcile the activities of MNE groups with their counterparts in other economies \(see paragraph \[21.55\]\).](#)

## **E. Macroeconomic Indicators and Supplementary Information to Monitor the Impact of Globalization**

### **1. Existing Macroeconomic Indicators**

#### **Key Indicators other than GDP**

- 23.65 Traditionally, analysis of economic activity within an economy focused on GDP as a broadly defined, internationally consistent measure of productive activity. Considering various ~~recent~~ economic developments, including increased globalization, the 2025 SNA has given increased prominence to other key indicators, such as gross/net national income (GNI/NNI), gross/net national disposable income (GNDI/NNDI), and household (adjusted) disposable income. These indicators are generally less affected by globalization and less sensitive to the impact of MNE activities than GDP. This is an important factor to consider, especially for economies with significant MNE presence. As such, indicators other than GDP may better reflect the impact of the underlying economic activities of MNEs on an economy's residents.
- 23.66 To illustrate these differences, consider a direct investment affiliate that is wholly owned by a foreign parent and is engaged in capital-intensive production. Because the production process is capital-intensive, most of the value added accrues as operating surplus to the foreign parents, perhaps primarily as reinvested earnings on foreign direct investment, whereas only a relatively small part of the value added remains in the domestic economy as remuneration of employees. Similarly, if an MNE engages in distorted transfer pricing to boost the income of an affiliate in a lower tax economy and it is not possible to replace the distorted transfer prices with exchange values in the compilation of the accounts, the transfer pricing will have less effect on GNI than on GDP. In both cases, comparing GDP with GNI, GDP includes the full value added, whereas GNI excludes the property income that accrues to foreign investors, whether in the form of dividends or interest that are repatriated to the parent or in the form of reinvested earnings on foreign direct investment. The GNI comes closer to measuring the economic flows that are retained by the economy's residents.
- 23.67 Similarly, net measures such as net national income (NNI) will tend to better capture the impact of MNE activities on domestic residents than the gross measure. [Insert reference to relevant paragraphs on net measures] For example, consider an economy to which an MNE relocates a large amount of IPPs. The IPP generates on-going production and income in the form of royalties or license fees, which directly feed into the measurement of GDP. GNI excludes the property income that accrues to foreign investors, but NNI goes one step further by also considering the depreciation that is associated with the IPP. If an MNE affiliate engages in activities that result in the depletion of mineral and energy resources, the depletion is now also reflected in NNI (but not in GNI). Similarly, the depletion of biological resources is deducted in the calculation of NNI, whereas the regeneration of biological resources is recorded as an addition to GDP, GNI, and NNI.
- 23.68 When current transfers represent a large share of an economy's income, net national disposable income (NNDI) can provide a better measure of the income available to residents for consumption or saving. Furthermore, when interest is focused primarily on the material well-being of households, indicators such as net household (adjusted) disposable income may provide the best summary of economic conditions. The latter indicators are hardly affected by the activities of MNE groups; basically, only the remuneration from being employed by the domestic affiliates of the MNE group ~~feedfeeds~~ into household (adjusted) disposable income.

### **2. Supplementary Data**

#### **Additional Granularity in the Institutional Sector Accounts and External Accounts, including Special Purpose Entities**

- 23.69 The institutional sector accounts show the full sequence of economic accounts from output and value added

to net lending and borrowing, the financial accounts, and the resulting balance sheets for institutional sectors. Adding granularity to these accounts and the external accounts based on ultimate control and ownership of corporations can highlight the full impact of MNE activities in the macroeconomic accounts and highlight not only foreign-controlled enterprises but also the domestic enterprises that are part of MNE groups. Because of the data intensity involved, it is recommended that the increased granularity be limited to the nonfinancial corporations sector and the financial corporations sector, and that the breakdown of MNE groups is not needed for any subsector.

- 23.70 For economies for which SPEs have a significant presence, it is recommended that SPEs be separately identified as “of which” items within the [institutional sector accounts]/[external accounts]. Separate identification of SPEs is important for better understanding the contribution of SPEs from both the national and external accounts perspective. For economies for which SPEs are significant, it is recommended that the presentation of the institutional sector accounts with enhanced granularity identify SPEs as an “of which” supplementary category for foreign-controlled financial and non-financial corporations.
- 23.71 Figure [23.6] [Note: if the table shown in Figure 23.6 appears in SNA Chapter 5/BPM7 Chapter 4, it should be referenced here] provides a template for the breakdown of the nonfinancial and financial corporations sector by domestic multinational corporations and foreign-controlled corporations as well as “of which” categories for SPEs.

**Figure 23.6. Template for Institutional Sector Accounts and External Accounts with Additional Granularity and SPEs**

### Supplementary (Foreign) Direct Investment Statistics

- 23.72 The increasingly complex financing and ownership structures of MNE groups, driven by many factors such as tax optimization or labour and transport cost reduction, play an important role in direct investment relationships. (Foreign) direct investment often involves MNEs channeling investments through several economies, resulting in a large portion of direct investment flows in some economies being flows going in and out of the economy on their way to their final destination. This can make it difficult to interpret direct investment statistics and does not show the ultimate sources and destinations of direct investment when the statistics are compiled by immediate partner economy. Supplementary presentations of direct investment statistics, by ultimate investing economy, by ultimate host economy, etc., can help address these challenges. These supplementary statistics are covered in detail in [Annex 6 on Selected Issues on Direct Investment/ *BPM7* Annex 6, Selected Issues on Direct Investment]-] and the *OECD Benchmark Definition of Foreign Direct Investment*.

### Supplementary Presentation of Trade and Investment Income

- 23.73 To develop indicators on GVCs and to better identify the role of MNEs in current account [international] transactions, a supplementary presentation of trade and investment income by characteristics of the enterprise, including ownership (e.g., domestically controlled or foreign-controlled) and size, is recommended. These indicators are not only useful for understanding international transactions by characteristics of the enterprise, but also for national accounts more generally, such as for the extended supply and use tables discussed in [Section F of this chapter paragraphs \[23.78-23.80\]](#).
- 23.74 Economies are encouraged to compile data on goods trade by enterprise characteristics (TEC) and services trade by enterprise characteristics (STEC). Many economies have added information on whether the enterprise is foreign or domestically owned to their TEC and STEC statistics. These statistics can answer questions such as: What kind of enterprises are behind the trade flows of goods and services? What is the share of small and medium-sized enterprises in total trade? What is the share of enterprises that trade with a certain partner economy and the amount of trade value they account for? These statistics can enable compilers to prepare a supplementary presentation that disaggregates exports and imports of goods and services and external flows of investment income broken down by ownership, size-class of enterprises, trading partner, product, and industry.
- 23.75 Table [23.2] provides a template for this supplementary presentation. The main breakdown is by domestic versus foreign ultimate control. The template also calls for the identification of small and medium-sized enterprises (SMEs) that employ fewer than a threshold of a given number of employees. It will be beneficial to further divide SMEs into independent SMEs (i.e., not a part of a group) and those that are part of a group to try to identify the SMEs that might benefit from capital inputs of affiliated parties. Many economies use the threshold of fewer than 250 employees. This threshold is encouraged to enhance international comparability, but other thresholds could also be considered. In cases where the underlying data are not collected or available at the enterprise level (for example, imports of goods or services by individuals), the transactions should be reported as "Unknown". It will be beneficial to further divide SMEs into independent SMEs (i.e., not a part of a group) and those that are part of a group to try to identify the SMEs that might benefit from capital inputs of affiliated parties.

23.76 While the template represents a recommended level of disaggregation, some economies may be able to provide further disaggregation along certain dimensions, whereas in other cases economies may not be able to provide the recommended level of disaggregation because of their own confidentiality criteria for disseminating the information or lack of detailed data. However, the most economically relevant breakdown possible should be considered when publishing these statistics.

### Other Supplementary Balance of Payments Statistics

- 23.77 Detailed balance of payments statistics are useful for the analysis of GVCs (see below). In particular, reporting of the following items is encouraged: total value of re-exports and main product and/or partner breakdown; total value of goods acquired or sold under merchanting and the main products and/or major trading partners; a reconciliation table between international merchandise trade statistics and balance of payments goods statistics; product and partner breakdown of total trade in goods on a balance of payments basis and geographical [breakbreakdown](#) of Extended Balance of Payments Services categories.

### Extended Supply-Use Tables

- 23.78 Extended supply and use tables (eSUTs) are extended tables designed to provide more granularity regarding transactions associated with globalized production processes in a flexible manner that allows for a number of possible extensions. This additional granularity can support the compilation of [Trade in Value Added \(TiVA\)](#) and GVC thematic accounts. Extensions may include details on origin (imports), destination (exports), goods for processing, and re-exports, as well as breakdowns by firm such as by size-class of firm, trading status (e.g., export orientation), or control (e.g., foreign controlled or domestic entities that are part of an MNE group). The details on control may be identified by trade-by-enterprise characteristics (TEC) and services-trade-by-enterprise characteristics (STEC) data. Other possible extensions may include links to the generation of income accounts, employment statistics, and greenhouse gas emissions.
- 23.79 Various eSUT extensions can capture important differences in the input and output structure of different producers in the same industry that are absent from conventional supply and use tables and input-output tables. Under the eSUT approach, as with other extended tables and thematic accounts, economies can implement them according to their own priorities and resources in a way that is most relevant to their specific

**Commented [ED2]:** This subsection will most likely not be included in the *BPM7* version of the chapter.

needs, circumstances, and data availability. The objective of eSUTs is to create an integrated accounting framework that can link disparate data sources such as structural business statistics, trade-by-enterprise characteristics (TEC and STEC), foreign affiliate trade statistics, and trade data in a coherent framework. The eSUTs should be parsimonious in construction—that is, it is not necessary to break down all activities into more homogeneous groups. Like the GVC thematic accounts, the eSUTs only need to focus on ~~core~~[eSUTselected](#) activities. Compilers can focus on the industries and/or products where extra granularity is needed in the context of analyzing their economy. If there is no foreign presence in a given industry, then there is no granularity to be added.

- 23.80 The data collected for the supplementary presentation of trade and investment income described in paragraphs [23.~~XX~~73–23.~~XX~~76] can help improve the quality of eSUTs, GVC thematic accounts, and TiVA estimates. eSUTs build on national supply and use tables and input-output tables through the integration of more detailed data provided via MNE surveys, surveys for the balance of payments purposes, tax data, integrated business statistics, and reconciled trade statistics, among others. The eSUTs provide a holistic, integrated view to better understand the complexities and interactions in measuring the effects of globalization on production processes. They can also serve as useful and important inputs in the compilation of TiVA statistics and GVC thematic accounts. Detailed discussions and recommendations for eSUTs can be found in the *OECD Handbook on Extended Supply and Use Tables*.

### 3. Alternative Presentations

#### Alternative Presentation of Reclassified Special Purpose Entities

- 23.81 Economies in which SPEs are deemed to be especially important are encouraged to consider a voluntary option of extending the sequence of economic accounts by compiling a supplementary presentation of SPEs reclassified from their economies of legal incorporation to the economies of their parents. Although this alternative presentation is outside the [SNA/Manual] conceptual framework, it would allow users to see the effects of consolidating the flows of SPEs with the other flows of parents, giving users an idea of the effects of pass-through flows within MNEs on core macroeconomic indicators. Presenting SPE statistics on a nationality basis would be a complement to the residency-based statistics and not a substitute. Compiling these supplementary statistics should be considered only for economies for which SPEs are deemed important, particularly where resident MNEs set up many foreign SPEs or non-resident MNEs set up many resident SPEs. This supplementary approach of compiling macroeconomic aggregates is considered too ambitious and resource intensive to implement consistently across economies in which SPEs are not deemed important.

### 4. Statistics on the Activities of Multinational Enterprises

References:

Eurostat, *Recommendations Manual on the Production of Foreign Affiliates Statistics*.

Organization for Economic Cooperation and Development (OECD), *OECD Benchmark Definition of Foreign Direct Investment*.

OECD, *OECD Handbook on Economic Globalisation Indicators*

United Nations, *Manual on Statistics of International Trade in Services*

[Summary version of subsection for 2025 SNA]

- 23.82 To complement statistics on foreign direct investment and other globalization indicators, information on foreign-controlled enterprises is also provided through statistics on the Activities of Multinational Enterprises (AMNE statistics) and the closely related Foreign Affiliates Statistics (FATS). AMNE statistics cover a range of variables on foreign direct investment enterprises. This wider dataset is compiled separately from balance of payments and international investment position statistics (although the data may be collected in the

framework of compiling foreign direct investment), as the data relate to the overall holdings and activities of foreign direct investment enterprises rather than just the direct interrelations (positions and transactions) by them with related enterprises. That is, the objective of AMNE statistics is to provide an additional perspective on the impact of foreign direct investment that is complementary to data on international flows and positions.

- 23.83 AMNE statistics cover those foreign direct investment enterprises in which the direct investor (or a group of investors in combination) directly or indirectly holds or controls a majority of the voting power (i.e., subsidiaries). This coincides with the scope of foreign controlled corporations in the SNA but differs from the scope of foreign direct investment enterprises due to the exclusion of associates.
- 23.84 For statistics on foreign-controlled enterprises in the compiling economy (inward AMNE statistics), the geographical attribution should be by the economy of the ultimate controlling parent. However, to facilitate links with foreign direct investment data, compilers are encouraged [to](#) also ~~to~~ provide some data in which attribution is based on the economy of the immediate investor (that is, the first foreign parent). Statistics for foreign enterprises controlled by foreign direct investors resident in the compiling economy (outward AMNE statistics) should be attributed based on the location of the enterprises whose activities are being described. Ideally, all AMNE variables should be attributed on the basis of the industrial activities of the establishment or enterprise, according to the United Nations *International Standard Industrial Classification of All Economic Activities* (ISIC). In addition, particular variables such as sales or output, exports, and imports may be attributed by the types of products produced and sold.

[Full version for BPM7]

#### Introduction

- 23.85 To complement statistics on direct investment and other globalization indicators, information on foreign-controlled enterprises is provided through statistics on the Activities of Multinational Enterprises (AMNE statistics) and the closely related Foreign Affiliates Statistics (FATS). AMNE statistics cover a range of variables on direct investment enterprises, as described below. This wider dataset is compiled separately from balance of payments and international investment position statistics (although the data may be collected in the framework of direct investment compilation), as the data relate to the overall holdings and activities of direct investment enterprises rather than just the direct interrelations (positions and transactions) by them with related enterprises. That is, the objective of AMNE statistics is to provide an additional perspective on the impact of direct investment that is complementary to data on international flows and positions. This section is designed to give an overview of the nature and compilation of AMNE statistics for the information of balance of payments compilers and users who may be considering this extended range of information.
- 23.86 AMNE statistics may be produced for both foreign-controlled enterprises in the compiling economy (a subset of inward direct investment; so-called “inward AMNE statistics”) and foreign affiliates controlled by MNEs in the compiling economy (a subset of outward direct investment; so-called “outward AMNE statistics”). In addition, outward AMNE statistics also may cover the activities of resident direct investors.
- 23.87 AMNE statistics can be important for the analysis of the performance of domestically and foreign-controlled enterprises, both in absolute terms and relative to the larger domestic and foreign universes of enterprises. Direct investment enterprises may be involved in activities such as research and development that benefit the domestic economy but may not be recorded as balance of payments transactions. Also, data on transactions in goods and services (with both residents and nonresidents) can provide an additional perspective to balance of payments data, as transactions by direct investment enterprises with unrelated persons could be significant.
- 23.88 Detailed discussion and recommendations for measuring AMNE and for FATS is found in the *Manual on Statistics of International Trade in Services*,<sup>4</sup> in the *OECD Handbook on Economic Globalisation Indicators*, and in the *OECD Benchmark Definition of Foreign Direct Investment*. A summary is provided here.

<sup>4</sup> The *Manual on Statistics of International Trade in Services* focuses on foreign affiliates producing services, but notes that most of its recommendations (all other than those related to industry/product groupings) for compiling these statistics are equally applicable to goods and services.

## Coverage

### *Universe or population*

23.89 AMNE statistics cover ~~these~~<sup>the subset of</sup> direct investment enterprises in which the direct investor (or a group of investors in combination) directly or indirectly holds or controls a majority of the voting power (i.e., subsidiaries). This differs from the scope of direct investment enterprises due to the exclusion of associates. ~~These~~<sup>AMNE</sup> statistics follow the definition of direct investment discussed in this *Manual* (paragraphs [6.8]–[6.24]) in that coverage is defined as those enterprises with majority foreign ownership of the voting power by a single investor or a group of investors acting together. Only those enterprises with foreign control are covered in AMNE statistics, thereby corresponding to the coverage of foreign-controlled corporations in Figure 23.6.

23.90—

23.91—

### *Economic variables for AMNE statistics*

23.92<sup>23.90</sup> Basic variables of substantial interest may include: sales (turnover) and/or output; employment; value added; exports and imports of goods and services; and number of enterprises.

23.93<sup>23.91</sup> Other variables that might be collected to supplement these data include: assets (both financial and nonfinancial); ~~reenumeration~~<sup>remuneration</sup> of employees; net worth; net operating surplus; gross fixed capital formation; taxes on income; research and development expenditures; total purchases of goods and services; and intra-group exports and imports.

23.94<sup>23.92</sup> The definitions of these variables are given in the *2025 SNA* and in the documents referenced above. It is also useful to have data for the total population of enterprises, or for the domestically-controlled enterprises on the same basis as AMNE statistics on inward direct investment, so performance can be compared with foreign-controlled enterprises.

## Statistical Units

23.95<sup>23.93</sup> In principle, most AMNE statistics could be collected at the enterprise group or enterprise level, or the level of individual business locations or establishments. Some indicators, such as total assets, are more naturally collected from enterprise groups or enterprises than from establishments. Direct investment statistics are usually collected from enterprise groups or enterprises, so collection of AMNE statistics at this same level facilitates linkages between the two types of data. However, because enterprise groups and enterprises are more likely than establishments to have activities in multiple industries, data that are classified on the basis of primary activity can be more difficult to interpret for enterprise groups and enterprises than for establishments. There are thus advantages and disadvantages associated with every basis of collection, and no recommendation is made as to the appropriate statistical collection unit. AMNE statistics ~~will~~<sup>will</sup> often be developed in the context of existing statistical systems, in which the statistical units are already defined, and in these cases there may be little choice in the units used.

## Time of Recording and Valuation

23.96<sup>23.94</sup> Time of recording and valuation are consistent with the *Manual*. Flow variables, such as output or value added, should cover the whole of the reference period (usually a year), and should be measured on an accrual basis. Stock variables, such as assets and net worth, should be as at the end of the reference period. All transactions and positions variables in principle should be measured at market value.

## Attribution of AMNE Variables

### *Geographic*

[23.97](#)[23.95](#) For statistics on foreign-controlled enterprises in the compiling economy (inward AMNE statistics), the geographical attribution should be by the economy of the ultimate controlling parent. However, to facilitate links with direct investment data, compilers are encouraged also to provide some data in which attribution is based on the economy of the immediate investor (that is, the first foreign parent). Statistics for foreign enterprises controlled by direct investors resident in the compiling economy (outward AMNE statistics) should be attributed based on the location of the enterprises whose activities are being described.

### *By activity and by product*

[23.98](#)[23.96](#) Ideally, all AMNE variables should be attributed on the basis of the industrial activities of the establishment or enterprise, according to the United Nations *International Standard Industrial Classification of All Economic Activities* (ISIC).

[23.99](#)[23.97](#) In addition, particular variables such as sales or output, exports, and imports may be attributed by the types of products produced and sold. Data on a product basis would identify the specific types of goods and services delivered through foreign-controlled enterprises and could most readily be compared with data on goods and services delivered through trade between residents and nonresidents, and to domestic output. However, some variables, such as value added and employment, do not readily lend themselves to a product classification.

[23.100](#)[23.98](#) As a longer-term goal, compilers are encouraged to work toward disaggregating, by product, some or all of the variables that lend themselves to this basis of attribution (such as sales (turnover) or output, exports, and imports). Product-based statistics are free of problems of interpretation related to secondary activities and are consistent with the basis of classification used for trade in goods and services in the balance of payments.

## Compilation Issues

[23.101](#)[23.99](#) There are two basic approaches, not necessarily mutually exclusive, to developing AMNE statistics. The first is to conduct surveys that directly request information on the operations of the covered enterprises (appropriate for both inward and outward AMNE statistics). The second identifies the subset of existing domestic enterprise data that is accounted for by foreign-owned firms (for inward AMNE statistics only). Direct investment registers may be used in either case to identify the units to be covered (as well as the economy of attribution, in the case of inward AMNE statistics). The collection of data for inward AMNE statistics can also be combined with the collection of data for supplementary data on foreign-controlled corporations in the external accounts.

[23.102](#)[23.100](#) For both inward and outward AMNE statistics, questions about key AMNE variables might be added to existing surveys of direct investment transactions and positions. However, because direct investment surveys may be conducted more frequently than AMNE statistics are required (for example, quarterly rather than annually) and require a quick turnaround, and also because AMNE statistics are needed for only the controlled portion of the direct investment universe, separate surveys may be a more appropriate way to proceed.

[23.103](#)[23.101](#) For inward AMNE statistics, it should be possible to link the direct investment statistics to the existing domestic economic statistics (for example, as collected for national accounts purposes) through the use of information on ownership structure to identify those resident enterprises that are foreign-controlled, as well as identifying the residence of the owner. AMNE statistics would be obtained as an aggregation of statistical variables across the foreign-controlled statistical population.

[23.104](#)[23.102](#) Additional questions may have to be added to direct investment surveys if information on the ultimate controlling parent is to be obtained.

## F. Analytical Tools

~~23.105~~23.103 The parts and components that make up a final product, whether a good or a service, are increasingly produced in different economies. Therefore, intermediate goods and associated services may cross national borders several times before they are assembled and sold as a final product. Moreover, international trade in goods and services is often intra-group trade, organized and led by MNEs.

~~23.106~~23.104 Policy demand for more statistical information on GVCs has grown significantly over recent years. Production fragmentation has deepened the divergence between gross flows, as recorded by traditional international trade statistics, and the data on production and final demand as accounted for in national accounts. This section introduces analytical tools that have been developed to better understand the relationship between globalization and the domestic economy.

### Trade in Value Added Indicators

References:

OECD (2021), *Guide to OECD's Trade in Value Added Indicators: 2021 Edition*.

United Nations Economic Commission for Europe (UNECE) (2015), *UNECE Guide to Measuring Global Production*

~~23.107~~23.105 Trade flows are generally reported on a bilateral gross basis—that is, an economy will report its exports and imports with each of its trading partners each time a change of ownership occurs. When the production process is fragmented across multiple economies, these bilateral gross trade flows taken by themselves may present a distorted view of the ultimate location of production.

~~23.108~~23.106 Consider the example shown in Figure [23.7]. Country A exports goods produced entirely within A, to Country B, which further processes them before exporting them to Country C where they are consumed. The value added of A is 100 (the same as the value of the exports), and B adds value of 10 to the goods, thus exporting 110 to C. Trade statistics show total global exports and imports of 210, but only 110 of value added has been generated in their production. The bilateral gross flows show C importing 110 from B and no trade at all with A, even though A is the main source of value added in the goods that C is importing from B. Note that C's trade deficit with the world is 110, and the gross trade flows suggest that the deficit is entirely due to its trade with B, even though most of the income associated with the imports of the good ultimately flow to A. The bilateral gross trade flows and any deficit or surplus associated with those flows are likely to provide a misleading picture of the location of production and the ultimate benefits or harms resulting from international trade.

**Figure 23.7. Inflated gross flows of trade**

Source: UNECE *Guide to Measuring Global Production* (2015).

**23.109** Several handbooks, guides, and statistics have been published since the last update of the [SNA/Manual] to better address the statistical challenges in understanding the nature of global production.<sup>5</sup> The **Trade in Value Added (TiVA)** approach addresses the double counting implicit in gross flows of trade. TiVA measures the value that is added by each economy and industry in the production of goods and services that are traded and consumed worldwide.

**23.110** The TiVA information thus incorporates information about the entire global value chain, providing information that policy makers can use to understand the global effects of their economy's trade flows, potentially impacting policies regarding the effects of trade on growth and competitiveness, global imbalances, macroeconomic shocks, employment, and the environment.

**23.111** The TiVA measurement model involves compiling a worldwide input-output table, which combines national supply and use tables with trade statistics. The worldwide input-output table enables the tracking of exports of one economy that are used as intermediate consumption in an industry of a second economy. The worldwide input-output table also includes columns that record the final demand in each economy and rows that record taxes less subsidies on products, value added at basic prices, and output for each industry in each economy.<sup>6</sup>

**23.112** Among the key indicators provided by the TiVA statistics are the domestic content of an economy's exports (that is, the domestic value added of exports as a percentage of total gross exports), a decomposition of an economy's gross exports by source economy in value added terms, and a similar decomposition of an economy's gross imports by source economy in value added terms. It is also possible to decompose the value-added content of exports by goods and services value added. Finally, these decompositions often show that a portion of the value added of imported intermediate goods reflects an economy's own domestic value added (from an earlier stage in the global value chain) that has "returned" to the economy.

**23.113** Granular TiVA statistics can be computed using eSUTs (see paragraphs [23.78-23.80]). Because TiVA estimates rely on supply and use (or input-output) tables from multiple economies, they have generally been compiled by international or regional organizations. Nevertheless, national statistics are the ultimate source of the data used in their compilation, and international cooperation is required in providing the data at the required level of detail. Where sufficiently detailed data are not available, the compiler necessarily has to make several assumptions. Efforts to improve the quality of national data on global value chains has contributed to the next analytical tool, the global value chain thematic account.

### Global Value Chain Thematic Account

Reference:

United Nations, Department of Economic and Social Affairs, Statistics Division (2021), *Accounting for Global Value Chains: GVC Satellite Accounts and Integrated Business Statistics*, Studies in Methods, Series F no. 120.

**23.114** GVCs, coordinated and headed by lead firms, represent interlinked core production activities and supporting activities to produce a final product. GVCs consist of the full range of activities that firms and workers do to bring a product from its conception to its end use. This includes activities such as research and development, production, transportation and distribution, marketing and sales, and after-sales services to the final consumer. While one cannot fully see the activities of GVCs in conventional national accounts statistics, a GVC thematic account uses a bottom-up approach that looks at a specific production chain within the framework of national accounts.

**23.115** The United Nations Handbook, *Accounting for Global Value Chains: GVC Satellite Accounts and*

**Commented [ED3]:** This subsection will most likely not be included in the BPM7 version of the chapter.

<sup>5</sup> For example, see OECD (2021), *Guide to OECD's Trade in Value Added Indicators: 2021 Edition*. International and regional organizations have also compiled regional versions of TiVA accounts for Europe, Asia, and North America.

<sup>6</sup> A more complete description of the construction of TiVA statistics is available in Chapter 7 of the UNECE *Guide to Measuring Global Production*.

*Integrated Business Statistics*, highlights the role of a GVC thematic account approach that can be used to identify and articulate a GVC for a specific product or group of products produced within a GVC. The GVC thematic account consists of GVC-specific supply and use tables (SUTs), either national or multi-country, based on an enterprise-centered approach. It combines integrated and more detailed business statistics and information on business lines and functions and GVC-specific institutional sector accounts. Accordingly, it includes production, including generated income and employment, investment income, and investment (both nonfinancial and financial), and provides information on balance sheets. This level of detail is not readily available in the existing accounting presentation at the level of sectors or sub-sectors that contain the activities of significant GVCs in an economy.

<sup>23.116</sup> <sup>23.114</sup> National (or multi-country) GVC-specific accounts would be compiled from national supply and use tables. The scope of the GVC and the identification of the firms participating in the supply chain of the GVC must first be determined by the compilers. The integration of information starts from the compilation of national supply and use tables with a common breakdown of industries and products. The breakdown at industry level explicitly identifies the relevant International Standard Industrial Classification (ISIC) divisions and groups for the GVC. Similarly, the breakdown at the product level explicitly identifies the GVC-relevant products. However, there are significant additions required for a comprehensive GVC analysis as outlined in the United Nations Handbook.

<sup>23.117</sup> <sup>23.115</sup> A global enterprise can organize its core production activities (production of goods and services to be sold in the market) in a number of different business lines. Such an enterprise could be a lead firm for various GVCs in different specific industries. Therefore, business, trade, and investment data for a GVC thematic account would need to be collected from the business line of a global enterprise to allow for the correct data specification of the industry-specific GVCs controlled by the lead firm. The enterprise or enterprise group would be able to delineate the statistical units in each of its business lines and further by each business function. The activities of the lead firm are recorded in the country of its residence. In addition, in order to reflect the governance structure in the supply and use tables, there should be a further breakdown of the firms in the ISIC categories that correspond with the business functions of a GVC undertaken in the economic territory to reflect if the firm is foreign controlled or nationally controlled and if the firm is part of the GVC or not.

<sup>23.118</sup> <sup>23.116</sup> In a similar way, the list of standardized products explicitly identified in the GVC-specific accounts reflects the GVC-related products which include the final product of the GVC and the intermediate goods and services that are used to produce the final product. Finally, because of the multi-country nature of the GVCs, the trade of these products between the GVC partner countries would also be explicitly shown.

<sup>23.119</sup> <sup>23.117</sup> The GVC thematic accounting framework is a flexible approach that can be implemented depending on an economy's needs and interests without overburdening or reducing the accuracy or consistency of the national accounts. In other words, GVC thematic accounts may focus on a single country or, preferably, expand to multi-country accounts with major GVC partners. Flexibility also applies in choosing one or more industries to focus on, with the selection based on the economic importance or dominance of the industry in the domestic economy and partner country markets. Moreover, GVC ~~satellite~~<sup>thematic</sup> accounts may comprise only one or several GVC-specific SUTs of interest, but preferably it will also include the GVC-specific institutional sector accounts.

<sup>23.120</sup> <sup>23.118</sup> Compilers can choose to focus on the most relevant GVCs for their economy based on their relative importance in terms of value added to the national economy, international investment, and trade relations, and/or to address specific policy questions. GVC thematic accounting aims to address the implicit homogeneity assumption among firms by deconstructing their contributions in the fragmented production process across multiple countries. Large firms, for example, capitalize on economies of scale, whilst affiliated firms may also have different production processes and different cross-border trade relationships than non-affiliated firms.

## Chapter 24: Insurance and pensions

### (OLD Chapter 17: Cross-cutting and other special issues, Part 1: The treatment of insurance and Part 2: Social insurance schemes)

- 24.1 ~~This part of chapter 17 is~~ This chapter provides an overview of insurance and pensions. Sections A to F are concerned with direct insurance and reinsurance. ~~It~~ They attempts to bring together all the entries in the accounts connected with non-life and life insurance and explain their interconnection. ~~Part 2~~ Sections G to K deals with pension and non-pension benefits under social insurance schemes.

#### A. Introduction to non-life insurance, life insurance and reinsurance

- 24.2 At its simplest, an insurance policy is an agreement between an insurance corporation and another institutional unit, called the policyholder. Under the agreement, the policyholder makes a payment (a premium) to the insurance corporation and, if or when a specified event occurs, the insurance corporation makes a payment (claim) to the policyholder. In this way, the policyholder protects itself against certain forms of risk; by pooling the risks the insurance corporation aims to receive more from the receipt of premiums than it has to pay out as claims. However, simply recording the actual premiums and claims paid in the sequence of economic accounts of the SNA would not reflect the links between premiums and claims. Instead, some actual transactions are partitioned and others are imputed in order to bring out the underlying economic processes actually taking place.
- 24.3 The most common form of insurance is called direct insurance whereby the policy is issued by an insurance corporation to another type of institutional unit but an important form of insurance is provided by one insurance corporation to another insurance corporation. This sort of insurance is called reinsurance.
- 24.4 Defining some of the terms peculiar to the insurance industry is a helpful preliminary to further discussion. For ~~direct~~ non-life and life insurance, the term premiums is used for payment to the insurance corporation; payments by the insurance corporation are called claims in the case of non-life policies and benefits in the case of life policies. ***The actual premium is the amount payable to the direct insurer or reinsurer to secure insurance cover for a specific event over a stated time period.*** Actual premiums are measured by the amounts payable after all allowances, discounts or bonuses are taken into account. Cover is frequently provided for one year at a time with the premium due to be paid at the outset though cover may be provided for shorter (or longer) periods and the premium may be payable in instalments, for example monthly.
- 24.5 ***The premium earned is the part of the actual premium that relates to cover provided in the accounting period.*** For example, if an annual policy with a premium of 120 units comes into force on April 1 and accounts are being prepared for a calendar year, the premium earned in the calendar year is 90. ***The unearned premium is the amount of the actual premium received that relates to the period past the accounting point.*** In the example just given, at the end of the accounting period there will be an unearned premium of 30, intended to provide cover for the first three months of the next year. ***A claim (benefit) is the amount payable to the policyholder by the direct insurer or reinsurer in respect of an event covered by the policy occurring in the period for which the policy is valid.*** Claims generally become due when the event occurs, even if the payment is made some time later. (The exception to the general rule is described in section C.) Claims that become due are described as claims incurred. In some contested cases the delay between the occurrence of the event giving rise to the claim and the settlement of the claim may be several years. ***Claims outstanding cover claims that have not been reported, have been reported but are not yet settled or have been both reported and settled but not yet paid.***

#### 1. Direct insurance

- 24.6 There are two types of direct insurance, life and non-life insurance. ***Life insurance is an activity whereby a policyholder makes regular payments to an insurer in return for which the insurer guarantees to provide the policyholder (or in some cases another nominated person) with an agreed sum, or an annuity, at a given date or earlier if the policyholder dies beforehand.*** The sum payable under the policy (benefit) may be fixed or may vary to reflect the income earned from the investment of premiums during the period for which the policy operates.

For policies with varying returns, the terms “with-profits” life insurance or endowment policy are generally used. Although the date and sum may be variable, a claim is always paid in respect of a life policy. *Non-life insurance is an activity similar to life insurance except that it covers all other risks, accidents, sickness, fire, etc.* A policy that provides a benefit in the case of death within a given period but in no other circumstances, usually called term insurance, is regarded as non-life insurance because, as with other non-life insurance, a claim is payable only if a specified contingency occurs and not otherwise. In practice, because of the way in which insurance corporations keep their accounts, it may not always be possible to separate term insurance from other life insurance. In these circumstances, term insurance may have to be treated in the same way as life insurance for purely practical reasons.

24.7 What life and non-life insurance have in common is that they both involve spreading risk. Insurers receive many (relatively) small regular payments of premiums from policyholders and pay much larger sums to claimants when the contingencies covered by the policy occur. For non-life insurance, the risks are spread over the whole population that takes out the insurance policies. For example, an insurance corporation determines the premiums charged for vehicle insurance in a year by relating them to the amount of claims it expects to pay on vehicle insurance in the same year. Typically, the number of claimants is much smaller than the number of policyholders. For an individual non-life policyholder there is no relationship between the premiums paid and the claims received, even in the long run, but the insurance corporation establishes such a relationship for every class of non-life insurance on a yearly basis. For life insurance, a relationship between premiums and claims over time is important both to the policyholders and to the insurance corporation. For someone taking out a life policy, the benefits to be received are expected to be at least as great as the premiums paid up until the benefit is due and can be seen as a form of saving. The insurance corporation must combine this aspect of a single policy with the actuarial calculations about the insured population concerning life expectancy (including the risks of fatal accidents) when determining the relationship between the levels of premiums and benefits. Further, in the interval between the receipt of premiums and the payment of benefits, the insurance corporation earns income from investing the premiums received. This income also affects the levels of premiums and benefits set by the insurance corporations.

24.8 Despite the similarity of the activity of life and non-life insurance, there are significant differences between them that lead to different types of entries in the accounts of the SNA. Non-life insurance consists of redistribution in the current period between all policyholders and a few claimants. Life insurance mainly redistributes premiums paid over a period of time as benefits paid later to the same policyholder. Essentially life insurance premiums and benefits are financial transactions and not current transactions.

24.9 One way in which a regular income stream can be obtained in return for an upfront payment of a lump sum is via an annuity. Annuities are usually offered by life insurance corporations and so a discussion of the recording for annuities in the [sequence of economic accounts](#)<sup>SNA</sup> is given at the end of this part.

24.924.10 [In some countries, one can observe hybrid insurance products that are a mixture of life and non-life insurance. These products should be allocated to one category or the other depending on which features are predominant, with the share of premiums allocated to claims for insured events \(non-life insurance\) versus the share of premiums allocated to payouts at maturity \(life insurance\) to be used to determine the allocation.](#)

## 2. Reinsurance

24.1024.11 Just as an individual institutional unit protects itself against the financial consequences of loss or damage, so an insurance corporation may also protect itself against an unexpectedly large number of claims, or exceptionally heavy claims, by taking out a reinsurance policy with another insurance corporation. All insurance corporations may take out some form of reinsurance but there tend to be a few large corporations that specialize in issuing reinsurance policies. Because these corporations are concentrated in a few financial centres, many of the flows associated with reinsurance involve transactions with the rest of the world. It is common for reinsurers to take out reinsurance policies with other insurance corporations to spread their risks further. This sort of reinsurance is called retrocession.

24.1124.12 Reinsurance policies are most common for non-life policies but may also apply to life insurance policies. There are two types of reinsurance, proportionate reinsurance and excess of loss reinsurance. Under a proportionate reinsurance contract, the reinsurer accepts an agreed proportion of the risks; this proportion of the

premiums is “ceded” to the reinsurer who then meets the same proportion of the claims. In this case, any reinsurance commission paid by the reinsurer to the policyholder (either a direct insurer or another reinsurer) is treated as a reduction in actual reinsurance premiums payable. In excess of loss reinsurance, the reinsurer undertakes to pay all losses over a given threshold. If there are no or few claims above the threshold, the reinsurer may pass a share of his profits to the direct insurer. By convention, profit-sharing is treated as a current transfer from the reinsurer to the direct insurer in a way similar to the payment of claims.

### 3. The units involved

24.1224.13 The institutional units involved in direct insurance and reinsurance are pre-eminently insurance corporations. In principle it is possible for another type of enterprise to carry out insurance as a non-principal activity, but usually the legal regulations surrounding the conduct of insurance mean that a separate set of accounts covering all aspects of the insurance activity must be kept; thus in the sequence of economic accounts~~SNA~~ a separate institutional unit, classified to the insurance corporations and pension funds subsector, is identifiable. Sometimes government may conduct other insurance activities, but again it is likely that a separate unit can be identified. Having noted that exceptionally other sectors may be involved, in what follows it is assumed that all insurance is carried out by insurance corporations, either resident or non-resident.

## B. Output of direct insurance and reinsurance

24.1324.14 Under a non-life insurance policy, the insurance company accepts a premium from a client and holds it until a claim is made or the period of the insurance expires. In the meantime, the insurance company invests the premium and the investment income is an extra source of funds from which to meet any claim due. The investment income represents income foregone by the client and so is treated as an implicit supplement to the actual premium. The insurance company sets the level of the actual premiums to be such that the sum of the actual premiums plus the investment income earned on them less the expected claim will leave a margin that the insurance company can retain; this margin represents the output of the insurance company. Within the SNA, the output of the insurance industry is determined in a manner intended to mimic the premium setting policies of the insurance corporations. To that end, four separate items need to be defined. These are actual premiums earned, premium supplements, claims (or benefits) incurred and reserves. Each of these is discussed in turn before discussing the measurement of output for direct non-life insurance, direct life insurance and reinsurance respectively.

### 1. Actual Premiums earned

24.1424.15 As explained in section A, an important distinction is made between actual premiums, which are payable for cover in a given period and actual premiums earned that are the proportion of actual premiums, relating to the accounting period in question rather than to the period covered by the insurance policy.

### 2. Premium supplements

24.1524.16 For life insurance in particular, but also to a lesser extent for non-life insurance, the total amount of claims payable in a given period often exceeds the premiums receivable. The insurance corporation can accept this because the contingencies covered by the policies do not occur, even for the whole population covered, at the same time as the premiums are paid. Premiums are usually paid regularly, often at the start of an insurance period, whereas claims fall due later, in the case of life insurance often many years later. In the time between the premium being paid and the claim being payable, the sum involved is at the disposal of the insurance corporation to invest and earn income from it. These amounts are called reserves. The income earned on the reserves allows the insurance corporations to charge lower premiums than would be the case otherwise. An adequate measure of the service provided must take account of the size of this income as well as the relative size of premiums and claims.

24.1624.17 The income concerned comes from the investment of the reserves of the insurance corporations, which represent liabilities towards the policyholders. For non-life insurance, even though a premium may be payable at the start of a period of cover, the premiums are only earned on a continuous basis as the period passes. At any

point before the end of the cover, the insurance corporation holds an amount due to the policyholder relating to services and possible claims to be provided in the future. This is a form of credit extended by the policyholder to the insurance corporation described as actual unearned premiums. Similarly, although claims become due for payment by the insurance corporation when the contingency specified in the policy eventuates, they may not be actually payable until some time later, often because of negotiation about the amounts due. This is another similar form of credit, described as reserves against claims outstanding.

~~24.17~~24.18 Similar reserves exist for life insurance but in addition there are two other elements of insurance reserves, actuarial reserves for life insurance and reserves for with-profit insurance. They represent amounts set aside for payments of benefits in future. Usually the reserves are invested in financial assets and the income is in the form of investment income (interest and dividends). Sometimes, however, they may be used to generate net operating surplus either in a separate establishment or as a secondary activity. The most common example is from real estate.

~~24.18~~24.19 It is common with life insurance policies for amounts to be explicitly attributed by the insurance corporation to the policyholders in each year. These sums are often described as bonuses. The sums involved are not actually paid to the policyholders but the liabilities of the insurance corporation towards the policyholders increase by this amount. This amount is shown as investment income attributed to the policyholders. The fact that some of it may derive from holding gains does not change this designation; as far as the policyholders are concerned it is the return for making the financial asset available to the insurance corporation. ~~In addition, all the income from the investment of non-life reserves and any excess of income from the investment of life reserves over any amounts explicitly attributed to the policyholders, are shown as investment income attributed to policyholders, regardless of the source of the income.~~

~~24.19~~24.20 All investment income attributed to policyholders, whether explicitly by the insurance corporation or implicitly within the SNA, is shown as payable to the policyholders in the ~~distribution of primary~~allocation of earned income account. For non-life insurance, the same amount is then repaid to the insurance corporation as premium supplements in the ~~secondary distribution of income~~transfers other than social transfers in kind account. For life insurance, premiums and premium supplements as well as benefits are shown in the financial account.

~~24.20~~24.21 For direct non-life insurance, the investment income attributed to the policyholders should, in principle, be made according to the proportion of reserves attributed to the different classes of insurance and policyholders. In practice, the usual method is to distribute the investment income in proportion to the actual premiums payable. For direct life insurance, all policyholders are individuals and so the investment income is attributed to households (possibly including some non-resident households).

### 3. Claims and benefits

#### Non-life insurance claims

~~24.21~~24.22 The level of claims made on non-life insurance policies varies from year to year and there may be exceptional events that cause a particularly high level of claims. However, the concept of insurance service is the service of providing cover against risk; production occurs continuously and not simply when the risk occurs. As such, its measurement should not be affected by the volatility of the occurrence of the risk. Neither the volume nor the price of insurance services is directly affected by the volatility of claims. The insurance company sets the level of premiums on the basis of its own estimation of the likelihood of claims. For this reason, the formula used in the integrated framework of national accounts~~SNA~~ for the calculation of output should not use ~~not~~ actual claims but a figure based on past experience and future expectations. The term “adjusted claims” is used to describe the level of claims used in determining the value of output.

~~24.22~~24.23 The figure for adjusted claims may be derived statistically in an expectations approach based on previous experience of the level of claims. In considering the past history of claims payable, however, allowance must be made for the share of these claims that are met under the terms of the direct insurer’s reinsurance policy (if any). For example, when the direct insurer has an excess of loss reinsurance, he sets the level of premiums to cover losses up to the maximum loss covered by his reinsurance policy plus the reinsurance premium he must pay. Under a proportionate reinsurance policy, he sets his premiums to cover the proportion of claims he has to pay plus the reinsurance premium.

~~24.23~~~~24.24~~ Alternatively, an approach using information from the accounts of the insurance corporation may be adopted. These may include an equalization provision, which is an adjustment to reflect the variations in claims from one year to another. Whichever method is used, therefore, the adjusted claim figure approximates the expected level of claims.

### **Life insurance benefits**

~~24.24~~~~24.25~~ Life insurance benefits are the amounts payable under the policy in the accounting period in question. No adjustment for unexpected volatility is necessary in the case of life insurance.

## **4. Reserves**

~~24.25~~~~24.26~~ The concept of reserves used in the formula for deriving the value of insurance output corresponds to the definition of non-life insurance technical reserves and life insurance and annuity~~ies~~ entitlements as defined in chapter ~~13~~~~14~~. These cover provisions for unearned premiums, for unexpired risks (i.e., the amounts set aside in addition to the unearned premiums in respect of risks to be borne by the insurer after the end of the financial year in order to provide for all claims and expenses in excess of the related unearned premiums), claims, or benefits, outstanding and reserves for bonuses and rebates, the latter applying in the main to life insurance only. The coverage of unearned premiums and claims outstanding is given in section A.

## **5. Defining insurance output**

### **Non-life insurance**

~~24.26~~~~24.27~~ The output of the insurance corporation represents the service provided to the policyholders. The output of direct non-life insurance is based on the principle of adding premiums and premium supplements and deducting adjusted claims incurred.

~~24.27~~~~24.28~~ If an expectations approach is being used, the formula to calculate output takes the following form:

Actual premiums earned;

*plus* premium supplements;

*minus* adjusted claims incurred;

where adjusted claims are estimated from past experience. In such a case, conceptually premium supplements should also be estimated on the basis of past experience. However, since premium supplements, i.e., the investment income, excluding holding gains and losses, derived from the investment of the non-life insurance technical reserves, are less volatile than claims, in practice no such adjustment may be necessary. If a statistical basis is to be used for estimating output, it is advisable to use information broken down by “line of business”, that is for motor insurance, buildings insurance, etc. separately.

~~24.28~~~~24.29~~ Alternatively, an accounting approach may be used whereby output is calculated as:

Actual premiums earned;

*plus* premium supplements;

*minus* adjusted claims incurred;

where adjusted claims are determined by using claims due plus the changes in equalization provisions and, if necessary, changes to own funds.

~~24.29~~~~24.30~~ If the necessary accounting data are not available and the historical statistical data are not sufficient to allow reasonable average estimates of output to be made, the output of non-life insurance may be estimated as

the sum of costs (including intermediate costs, labour and capital costs) plus an allowance for “normal profit”. However, since any reasonable estimate for “normal profit” is likely to involve expected claims, this option is hardly different from the expectations approach.

## Life insurance

~~24.30~~24.31 The output of direct life insurance is calculated separately as:

Actual premiums earned;

*plus* premium supplements;

*minus* benefits due;

*minus* increases (plus decreases) in life insurance and annuity entitlements~~actuarial reserves and reserves for with-profits insurance.~~

~~24.31~~24.32 If adequate data are not available for the calculation of life insurance according to this formula, an approach based on the sum of costs, similar to that described for non-life insurance, may be used. As for non-life insurance, an allowance for normal profits must be included.

## Reinsurance

~~24.32~~24.33 The formula to calculate the output of reinsurance services is exactly analogous to those for direct insurance. However, because the primary motivation of reinsurance is to limit the direct insurer’s exposure to risk, a reinsurer deals with exceptionally large claims as a matter of normal business. For this reason, and because the market for reinsurance is concentrated in relatively few large firms worldwide, it is less likely that the reinsurer will experience an unexpectedly large loss than a direct insurer does, especially in the case of excess of loss reinsurance.

~~24.33~~24.34 The output of reinsurance is measured in a way similar to that for direct non-life insurance. However, there are some payments peculiar to reinsurance. These are commissions payable to the direct insurer under proportionate reinsurance and profit sharing in excess of loss reinsurance. Once these are taken into account the output of reinsurance can be calculated as:

~~Total a~~Actual premiums earned less commissions payable;

*plus* premium supplements;

*minus* both adjusted claims incurred and profit sharing.

## C. All the transactions associated with non-life insurance

~~24.34~~24.35 This section describes the full set of entries needed in the accounts to record all the implications of a non-life insurance policy. Policies may be taken out by corporations, government units, NPISHs, households and units in the rest of the world. However, when a policy taken out by a member of a household qualifies as social insurance, the entries required are as described in ~~part 2~~sections G to K of this chapter on social insurance and not as described here.

### 1. Net-pPremiums less service charges and consumption of insurance services

~~24.35~~24.36 The actual premiums earned~~payable~~ and the premium supplements are shown in the sequence of economic accounts~~SNA~~ divided between two types of transactions. The first is the value of the output of insurance, which is shown as either consumption or export of insurance services. The second is ~~net~~-premiums earned less service charges by the insurance corporations. Net-pPremiums less service charges are defined as actual premiums earned plus premium supplements less the insurance service charge payable by the policyholders. Because of the way in which the value of the service output is defined, ~~net premiums for~~ non-life

insurance premiums less service charges are equal in total to adjusted, and not actual, claims. Any variation between adjusted and actual claims represents a transfer between the policyholders and the insurance corporation. Over time, a transfer in one direction is offset by one in the other.

24.3624.37 Insurance services are consumed by those sectors (and the rest of the world) that pay premiums. Estimates of the value of consumption by sector are usually made by allocating the total value of the service in proportion to the actual premiums payableearned. Estimates of ~~net~~ premiums less service charges are then made by deducting the consumption of services from the total value of actual premiums payableearned plus the value of the premium supplements. (Because premium supplements are also allocated in proportion to actual premiums earned, the ~~net~~ premiums less service charges are also in effect allocated in the same proportions as the actual premiums earned.)

## 2. Recording non-life insurance claims

24.3724.38 The time of recording claims incurred is generally in the period in which the event to which the claim relates took place. This principle is applied even when, in the case of disputed claims, the settlement may take place years after the event concerned. An exception is made in cases where the possibility of making a claim is recognized only long after the event has happened. For example, an important series of claims were recognized only when exposure to asbestos was established as a cause of serious illness and was judged to give rise to claims under an insurance policy valid at the time of the exposure. In such cases the claim is recorded at the time that the insurance company accepts the liability. This may not be the same time as when the size of the claim is agreed on or when the claim is paid.

24.3824.39 Because the formula for output uses adjusted claims and not actual claims, only when the actual claims happen to be the same value as expected claims will ~~net~~ premiums less service charges and claims be equal in a given period. They should however be approximately equal over a period of years excluding a year in which a disaster is recorded.

24.3924.40 Claims are normally recorded as current transfers payable by the insurance corporation to the policyholder. In some circumstances, an insurance corporation may set the level of premiums so low that they are not expected to cover costs and the predicted level of claims. This may happen when the surplus from one line of business, for example home insurance, is being used to cross-subsidise another line of business, for example, vehicle insurance.

24.41 There is one case where claims may be recorded as capital transfers rather than current transfers and that is in the wake of a major catastrophe. The criteria for when the effects of a catastrophe should be treated like this must be determined according to national circumstances but these may involve the number of policyholders affected and the amount of the damage done. The rationale for recording the claims as capital transfers in this case comes from the fact that many of the claims will relate to destruction or serious damage to non-financial assets such as dwellings, buildings and structures, inventories and valuables. Damage corresponding to a normal level of claims is covered by, for example, consumption of fixed capitaldepreciation or losses from inventories. These losses are thus captured as current expenditure elsewhere in the system. However, major losses in the wake of a catastrophe are recorded as the result of unforeseen events in the other changes in assets accounts and omitted from current expenditures. The recommendation is thus to record claims as current or capital transfers analogously.

24.4024.42 It is noted the recording of claims due to catastrophic events as capital transfers is restricted to damages to non-financial assets. Claims due to losses to consumer durables should be recorded as income transfers. The increase in disposable income would thus cancel out final consumption expenditure on replacing the damaged consumer durables, leaving saving unaffected. However, from a feasibility perspective, it may be difficult to differentiate catastrophic damages to non-financial assets, including inventories from similar damages to consumer durables. This would require further details on claims arising from insurance policies of households as consumers, to exclude those related to non-life insurance of dwellings and unincorporated enterprises. Unless this information is available, it is recommended to treat all claims arising from catastrophic events as capital transfers as the default option.

24.43 The recording non-life insurance claims due to catastrophic events as capital transfers may also have an impact on the recording of reinsurance. However, what constitutes an exceptional event for insurers at the national level may be business-as-usual for a large worldwide operating reinsurance company. As a consequence, one may end up with a national insurer recording claims due to a catastrophic event as capital transfers, while the related claims

received from the reinsurer are recorded as current transfers. Disposable income and saving of the national insurer would thus be positively affected by a catastrophic event, which is very counterintuitive. To avoid this, it is recommended to resolve them on a case by case basis. A strict delineation of catastrophic events would reduce the instances where this might occur.

24.4124.44 It is recommended that following a catastrophe, the total value of the claims related to the catastrophe should be recorded as a capital transfer from the insurance corporation to the policyholders. Information on the level of claims to be met under insurance policies should be obtained from the insurance industry. If the insurance industry cannot provide this information, one approach to estimating the level of the catastrophe-related claims is to take the difference between the adjusted claims and the actual claims in the period of the catastrophe.

24.45 A consequence of recording such claims as capital transfers means that the disposable income of households and other policyholders does not increase counter-intuitively as would be the case if the claims were recorded, as normal, as current transfers. The net worth of the policyholders will show the effects of both the destruction of assets (as an other volume change) and an increase (initially) in financial assets from the capital transfers. This recording is consistent with the recording of assistance by government of an NPISH to cover some or all of the costs of repairing or replacing the assets of those affected by the catastrophe who are not covered by an insurance policy.

### **3. Insurance services provided to and from the rest of the world**

24.4224.46 Resident insurance corporations frequently provide insurance cover to households and enterprises in the rest of the world, and resident households and enterprises may purchase cover from insurance corporations in the rest of the world. The investment income attributed by resident insurance corporations to policyholders includes an allocation to policyholders in the rest of the world. These non-resident policyholders then also pay premium supplements to the resident insurance corporation. This information should be available for resident insurers and should be included in the rest of the world account.

24.4324.47 Similar considerations also apply to the treatment of resident enterprises and households taking out policies with non-resident insurers. They receive imputed investment income from abroad and pay premiums and supplements to abroad. Estimation of the size of these flows is more difficult, especially when there is no resident insurer of the same type against which to make comparisons. However, very often the country providing the service will be known and it may be possible to use counterpart data to make estimates for the national economy. The level of transactions by residents should be known and the ratio of premium supplements to actual premiums earned in the economy providing the services could be used to estimate the investment income receivable and premium supplements payable.

### **4. The accounting entries**

24.4424.48 Altogether six pairs of transactions need to be recorded in respect of non-life insurance that is not part of social insurance; two pairs relating to the measurement of the production and consumption of the insurance service, three pairs relating to redistribution and one in the financial account. Under exceptional circumstances, a seventh transaction relating to redistribution may be recorded in the capital account. The value of the output of the activity, the investment income to be attributed to the policyholders and the value of the service charge are calculated specifically for other non-life insurance in the manner described above.

24.4524.49 The production and consumption transactions are as follows:

- a. Since all such activity by resident institutional units is undertaken by insurance corporations, the output is recorded in the production account of insurance corporations;
- b. The service may be consumed by any of the sectors of the economy or by the rest of the world; the value of the service is payable to insurance corporations. Payments by non-financial corporations, financial corporations, general government or ~~non-profit institutions~~ NPISHs constitute intermediate consumption, recorded in their production account. Insurance clearly associated with the productive activity of a household unincorporated enterprise is also recorded as intermediate consumption in the production account of households. Other insurance payments by households are part of final consumption

expenditure, recorded in the use of income account. Payments by the rest of the world are recorded as exports in the external account of goods and services.

24.4624.50 The redistributive transactions cover investment income attributed to policyholders in respect of non-life insurance, ~~net~~ non-life insurance premiums less service charges, and insurance claims:

- a. Investment income attributed to policyholders in respect of non-life insurance is recorded as payable by insurance corporations. It is recorded as receivable by all sectors and the rest of the world. Both payables and receivables are recorded in the allocation of primary earned income account.
- b. ~~Net~~ non-life insurance premiums less service charges are calculated as actual premiums earned plus premium supplements (equal to the investment income attributed to policyholders) less the value of the services consumed. These ~~net~~ premiums less service charges are payable by all sectors of the economy or the rest of the world and receivable by insurance corporations.
- c. Insurance claims incurred are payable by insurance corporations and receivable by all sectors of the economy and the rest of the world. Both ~~net~~ premiums less service charges and claims are recorded in the ~~secondary distribution of income~~ transfers other than social transfers in kind account.
- d. If some claims are to be treated as capital rather than current transfers, these are recorded in the capital account as payable to policyholders by insurance corporations.

24.4724.51 ~~Net~~ non-life insurance premiums less serviced charges should be recorded on the basis of the amounts due to obtain cover in the period of account, not the amounts actually paid in the period. Insurance claims should be recorded as payable on the date of the event concerned occurred, except in the type of case described above when the claim is recorded ~~when~~ at the time the insurance company accepts that a liability exists. An entry in the financial account records any difference between actual premiums payable and actual premiums earned and claims due and claims payable.

24.4824.52 By convention, unearned premiums and reserves against outstanding claims are shown as a change in liabilities of insurance corporation (with a negative sign if necessary) and a change in assets of all sectors and the rest of the world.

24.4924.53 An example of these flows is shown in table 1724.1.

Table 1724.1: Accounts for non-life insurance - ~~uses~~ expenditures

Table 1724.1 (cont): Accounts for non-life insurance - ~~resources~~ revenues

## D. All the transactions associated with life insurance

24.5024.54 This section describes the way in which recording of the entries for life insurance differs from non-life insurance. As for non-life insurance, but more significantly in practice, a life policy that qualifies as social insurance is recorded not as described here but as described in part 2 sections G to K of ~~the~~ this chapter. The major difference between a normal life insurance policy and one qualifying as social insurance is that under the former, the premiums and benefits ~~related to~~ from the policy are treated as mainly ~~changes in~~ reductions of wealth, recorded in the financial account. For a policy qualifying as social insurance, the contributions and benefits (pensions) are recorded as income transfers in the ~~secondary distribution of income~~ transfers other than social transfers in kind account. The reason for the different treatment is that an individual policy other than social insurance is entered into entirely on the initiative of the policyholder. Policies that qualify as social insurance reflect the intervention of a third party, usually the government or the employer, to encourage or oblige the policyholder to make provision for income in retirement. Distinguishing all payments made under social insurance schemes, including those coming from qualifying individual policies, shows how far social policies to ensure income in retirement are successful.

24.5124.55 The holder of a life insurance policy is always an individual. (If a company takes out an insurance policy

on the life of an employee, this should be treated as term insurance and therefore as non-life insurance in the SNA.) Life insurance transactions therefore take place only between insurance corporations and households, resident and non-resident. The production of the insurance services is matched by the value of the services consumed by households as part of final consumption expenditure and exports. The investment income attributed to insurance policyholders is treated as premium supplements. However, premiums and claims are not shown separately in the case of life insurance and are not treated as current transfers. Rather they constitute components of a net transaction recorded in the financial account, the financial asset involved being life insurance and annuities entitlements.

24.5224.56 Four pairs of transactions are recorded in the accounts; two pairs relate to production and consumption of the insurance service, one pair shows the attribution of investment income to the property holders and one pair shows the change in life insurance and annuities entitlements:

- a. The output of the life insurance activity is recorded in the production account for the insurance corporations.
- b. The value of the services consumed is recorded as final consumption expenditure payable by households in the use of disposable income account or as payable by the rest of the world (exports to non-resident households). Households may also make payments to non-resident insurers. Such payments are treated as imports of insurance services.
- c. Investment income attributed to insurance policyholders in respect of life insurance is recorded in the allocation of primary earned income account. Bonuses declared in connection with life policies are treated as being distributed to policyholders even if they exceed the investment income earned by the institution declaring the bonus. The investment income is recorded as payable by insurance corporations and receivable by resident households or non-resident households in the rest of the world.
- d. In the financial account, the item change in life insurance and annuities entitlements is shown as a change in assets of households and the rest of the world and a change in liabilities of insurance corporations. It is equal to actual premiums plus premium supplements (equal to the investment income attributed to policyholders: see paragraphs 24.16 to 24.21) less the value of the services consumed and less benefits due.

24.5324.57 An example of these flows is shown in table 1724.2.

**Table 1724.2: Accounts for life insurance - uses expenditures**

**Table 1724.2 (cont): Accounts for life insurance - resources revenues**

24.54 1. Annuities

24.55

24.58 Some life insurance policies yield a lump sum at a given date rather than a stream of payments. The lump sum may be used to purchase an annuity that itself converts a lump sum into a stream of payments. The recording of annuities is described in section F.

## **E. All transactions associated with reinsurance**

24.5624.59 Before discussing how the various elements contributing to the measurement of output of reinsurance are recorded in the SNA, it is necessary to describe how reinsurance is measured and recorded.

24.5724.60 The transactions between the direct insurer and the policyholder are measured as described in the previous section without any reference to the transactions between the direct insurer and the reinsurer. The transactions between the direct insurer and the reinsurer are recorded as an entirely separate set of transactions and no consolidation takes place between the transactions of the direct insurer as issuer of policies to its clients

on the one hand and the holder of a policy with the reinsurer on the other.

~~24.58~~24.61 The direct policyholder does not know, or need to know, whether the direct insurer involves a reinsurer to protect it against loss on the policy. The direct insurer receives actual premiums from its policyholders. Some of these are ceded to a reinsurer. The premiums are shown as being first payable to the direct insurer and then a lesser premium is payable to the reinsurer. This non-consolidation is sometimes referred to as gross recording on the part of the direct insurer. The alternative (net recording) would be to show part of the direct policyholders' premiums being paid to the direct insurer and part to the reinsurer but this option is not recommended either in commercial accounting or in the SNA.

~~24.59~~24.62 The actual premium payable by the direct insurer to the reinsurer is used by the reinsurer to earn investment income. This investment income, excluding any holding gains and losses, is treated as investment income payable to the direct insurer and returned to the reinsurer as a premium supplement. Thus a direct insurer pays investment income to its policyholders based on the whole of the actual premiums earned (or by approximation payable) but also receives investment income from the reinsurer corresponding to the amount of the premiums it has ceded to the reinsurer. The investment income receivable by the direct insurer from the reinsurer may be used to offset some of the investment income payable by the direct insurer to its policyholders but is not recorded explicitly as such.

~~24.60~~24.63 As with direct insurance, in exceptional cases, for example following a catastrophic natural disaster, some part of reinsurance claims may be recorded as capital transfers rather than as current transfers; see also paragraph 24.42.

~~24.61~~24.64 The whole of the output of the reinsurer represents intermediate consumption of the direct insurer holding the reinsurance policy. As noted above, many reinsurance policies are between insurance corporations resident in different economies. Thus the value of the output in these cases represents imports by the insurance corporation taking out the reinsurance policy and exports by the reinsurance corporation.

~~24.62~~24.65 The recording of flows associated with reinsurance resembles the recording for non-life insurance except that the policyholder of a reinsurance policy is always another insurance corporation.

~~24.63~~24.66 The production and consumption transactions are as follows:

- a. Since all such activity by resident institutional units is undertaken by insurance corporations, the output is recorded in the production account of insurance corporations. Reinsurance services may be, and often are, provided by non-resident units and thus are recorded in imports.
- b. The service may only be consumed by another insurance corporation, though this may be a non-resident unit, and is intermediate consumption of that unit unless the policyholder is non-resident in which case it is recorded as exports of the reinsurer.

~~24.64~~24.67 The redistributive transactions cover investment income attributed to policyholders in respect of reinsurance, ~~net~~ reinsurance premiums less service charges and reinsurance claims:

- a. Investment income receivable by reinsurance policyholders is payable by insurance corporations, resident or non-resident, and receivable by similar institutions either resident or non-resident.
- b. ~~Net-r~~ Reinsurance premiums less service charges are calculated as actual premiums earned plus premium supplements (equal to the investment income attributed to policyholders) less the value of the services consumed. These ~~net~~ premiums less service charges are payable by insurance corporations and receivable by [other] insurance corporations. (Either of the units due to make the payment or to receive it may be non-resident.)
- c. Reinsurance claims are payable by insurance corporations and receivable by [other] insurance corporations, either resident or non-resident. Both ~~net~~ premiums less service charges and claims are recorded in the ~~secondary distribution of income~~ transfers other than social transfers in kind account.
- d. Commissions payable by reinsurers to the insurance corporation as the reinsurance policyholder are treated as reductions in the premiums payable to the reinsurers.
- e. Profit sharing payable by the reinsurer to the direct insurer is recorded as a current transfer. (Although they are recorded differently, both commissions payable and profit sharing serve to reduce the output of the reinsurer.)

- f. If some direct insurance claims are treated as capital and not current transfers, any reinsurance claims relating to the same event should also be treated as capital transfers.

~~24.65~~24.68 An entry in the financial account records any difference between actual premiums payable and actual premiums earned and claims incurred and claims payable.

## F. Annuities

~~24.66~~24.69 The simplest case of a life insurance policy is one where a stream of payments is made by the policyholder to the insurance corporation over time in return for a single payment received as a claim at some point in the future. With the simplest form of annuity, the equivalent to the policyholder, called the annuitant, pays a single lump sum to the insurance corporation and in return receives a stream of payments either for a nominated period or for the rest of the annuitant's life (or possibly for the rest of the life of both the annuitant and a nominated other person).

~~24.67~~24.70 Annuities are organized by insurance corporations and are a means of risk management. The annuitant avoids risk by agreeing to accept a known payment stream (known either in absolute terms or subject to a formula, such as being index-linked) in return for parting with a considerable sum. The insurance corporation takes the risk of making more from investing the sum than is due to the annuitant. The rates of annuities are determined taking life expectancy into account. The insurance corporation has to pay more than originally planned to long-lived annuitants who may receive more than their original payment and the income earned on it. Those who die early receive less, possibly considerably less, and the insurance corporation receives more than expected.

### 1. How an annuity works

~~24.68~~24.71 It is simplest to explain the working of an annuity by means of an example. Suppose an insurance corporation offers an individual payments of 600 for life in return for a lump sum payment of 10 000 and further suppose that the insurance corporation expects the individual concerned to live for 25 years and that the discount rate being used is five per cent. As shown in figure ~~1724~~.1, the net present value of 600 for 25 years is only 8 700. Thus the remaining 1 300 represents the net present value of the service charges of about 90 per year the insurance corporation expects to make. Thus, whether the annuitant recognizes it or not, the insurance corporation offer of 600 a year is a ~~net~~-figure adjusted for service charges. The annuitant will actually be entitled to 690 a year but 90 is retained by the insurance corporation as a fee for its services.

**Figure ~~1724~~.1: Example of an annuity**

~~24.69~~24.72 Each year there is investment income payable to the annuitant equal to the unwinding of the annuity entitlements, equal to the discount factor of five percent on the remaining amount held by the insurance corporation. In the first year, the proportion of the investment income relating to the prepaid service charges~~premium~~ (1 300) is 65 and the remaining 25 of the service charge is met from a drawdown of the value of 1 300 to 1 275. The remaining investment income (435) adds to the value of the net annuity entitlement~~reserve~~ of 8 700. At the end of the first year, therefore, the annuity entitlement~~reserve~~ is 8 535; the original sum of 8 700 plus the ~~interest~~investment income of 435 and less the payment of 600. The drawdown on the start of year amount of the net annuity entitlement~~reserve~~ is thus 165 and the drawdown on the prepaid service charges~~premiums~~ is 25.

~~24.70~~24.73 This process continues year by year. As time progresses, the drawdown of the remaining reserves is an increasingly larger part of the payments due and the investment income payable a smaller part. In principle, every year the insurance corporation can review its assumptions about the remaining life expectancy of the annuitant and recalculate the amount available as a service charge. (In practice this is likely to be done at intervals and by cohort of annuitants.)

~~24.71~~24.74 The detailed numerical example is intended to demonstrate the way an annuity functions but in fact it is not necessary to undertake all these calculations to determine the output of the insurance corporation. The value

of output can be determined more simply as the total investment income due to the annuitant (500) less the amount payable to him (600) less the change in the value of the reserves (a reduction of 190), or 90 (500-600-(-190)). This result can be seen to be parallel to the measurement of life insurance except that there is no actual premium element.

## 2. The output associated with an annuity

24.7224.75 The output of an insurance corporation associated with administering annuities is calculated as:

the investment income attributable to the annuitants;

*minus* the amount payable to the annuitants (or surviving beneficiaries) under the terms of the annuity;

*minus* the change in the annuity ~~entitlements~~~~reserves~~ but excluding the initial payments for new annuities.

The amount of the investment income attributable to the annuitants is equal to the discount factor times the start of year reserves and is independent of actual investment income and holding gains or losses earned by the insurance corporation. The item is parallel to the concept of premium supplement in the life insurance context.

## 3. All the transactions associated with annuities

24.7324.76 There are three sets of transactions recorded for an existing annuity and further entries required for the initiation and termination of an annuity.

- A service charge associated with the annuity is payable every year. It is recorded as output of the insurance corporation and final consumption expenditure of the household to which the beneficiary belongs. This might be a non-resident household.
- Investment income equal to the discount factor times the level of annuity ~~entitlements~~~~reserves~~ at the beginning of the period is recorded in the ~~primary distribution of~~earned income account as payable by the insurance corporation and receivable by the household.
- The change in the value of the reserves for annuities is recorded in the financial account as payable by the household to the insurance corporation.

24.7424.77 When an annuity is initiated, there is a transfer of funds from the household to the insurance corporation. In many cases, however, this may simply be a “rollover” from a lump sum payable by that or another insurance corporation from the maturing of a normal life insurance policy immediately into an annuity. In such a case there is no need to record the payment of the lump sum and the acquisition of the annuity; there will simply be a change from life insurance reserves to annuity ~~entitlements~~~~reserves~~ in the insurance corporation ~~and pension fund~~ subsector. If an annuity is purchased independently of the maturing of a life insurance policy, this is recorded as a pair of financial transactions between the household and the insurance corporation. The household makes a payment to the insurance corporation and receives in return an asset arising from the terms of the annuity. The insurance corporation receives a financial asset from the household and incurs a liability towards it.

24.7524.78 Annuities are normally terminated by death, at which point any remaining reserves for that annuitant are transferred to the insurance corporation. However, assuming the insurance corporation has predicted life expectancy accurately, for the group of annuitants as a whole, the average funds remaining at death will be zero. If life expectancies change, revisions to the reserves must be made. For annuities in operation, an extension of life expectancies will reduce the amount available to the insurance corporation as a service charge, possibly making this negative. In such a case, the insurance corporation will have to draw on its own funds and hope to build these up again in future by associating higher service charges with new annuities.

## G. Introduction to social insurance

24.7624.79 Social insurance schemes are an important way in which individuals who participate in the scheme are

paid benefits, described as social benefits, when certain conditions exist that would adversely affect their welfare. Some social benefits, however, are payable independently of participation in a social insurance scheme. It is the conditions under which the benefits are payable that identify a social insurance scheme, not the nature of the benefits in themselves.

[24.77](#)[24.80](#) A social insurance scheme is a form of contract and always involves at least one unit other than the beneficiary. The other unit may be an employer, general government or a financial institution (often an insurance corporation) or sometimes a non-profit institution serving households (NPISH).

[24.78](#)[24.81](#) The objective of this part of the chapter is to describe how the various sorts of social benefits provided under social insurance schemes are recorded in the SNA. In order to do this, it is necessary to clarify the identifying characteristics of a social insurance scheme, the nature of the other unit involved, the types of benefits payable and the ways in which these are funded.

## **H. Basic definitions**

### **1. Social benefits**

[24.79](#)[24.82](#) Social benefits become payable when certain events occur, or certain conditions exist, that may adversely affect the welfare of the households concerned either by imposing additional demands on their resources or reducing their incomes. Social benefits may be provided in cash or in kind. There are a number of circumstances in which social benefits may be payable:

- a. The beneficiaries, or their dependants, require medical, dental or other treatment, or hospital, convalescent or long-term care, as a result of sickness, injuries, maternity, chronic invalidity, old age, etc. The social benefits may be provided in kind in the form of treatments or care provided free or at prices that are not economically significant, or by reimbursing expenditures made by households. Social benefits in cash may also be payable to beneficiaries needing health care.
- b. The beneficiaries have to support dependants of various kinds: spouses, children, elderly relatives, invalids, etc. The social benefits are usually paid in cash in the form of regular dependants' or family allowances.
- c. The beneficiaries suffer a reduction in income as a result of not being able to work, or to work full-time. The social benefits are usually paid in cash regularly for the duration of the condition. In some instances a lump sum may be provided additionally or instead of the regular payment. People may be prevented from working because of:
  - voluntary or compulsory retirement;
  - involuntary unemployment, including temporary lay-offs and short-time working;
  - sickness, accidental injury, the birth of a child, etc., that prevents a person from working, or working full time.
- d. The beneficiaries receive payments to compensate for suffering a reduction in income because of the death of the main income earner.
- e. The beneficiaries are provided with housing either free or at prices that are not economically significant or by reimbursing expenditure made by households. These are social benefits in kind.
- f. The beneficiaries are provided with allowances to cover education expenses incurred on behalf of themselves or their dependants. Occasionally education services may be provided in kind.

[24.80](#)[24.83](#) The above are typical circumstances in which social benefits are payable. However, the list is illustrative rather than exhaustive. It is possible, for example, that under some social insurance schemes other benefits may be payable. Conversely, by no means all schemes provide benefits in all the circumstances listed above. In practice, the scope of social insurance schemes is liable to vary significantly from country to country, or from scheme to scheme within the same country.

### **2. Social benefits provided by general government**

~~24.81~~24.84 Many social benefits are provided by general government. They may appear in the accounts as payments under social security, social assistance or social transfers in kind. Government may also be involved, as an employer, in other social insurance schemes.

~~24.82~~24.85 Social security is the name given to the social insurance scheme operated by general government. As will be explained below, in order to receive social security benefits, an individual must participate in a social security scheme.

~~24.83~~24.86 Social assistance is not a scheme and thus does not require participation. However, social assistance is frequently restricted to individuals with low incomes, disabilities or other particular characteristics. In some countries, though, a universal pension may be paid without any need for participation in which case it is part of social assistance also. There is a section discussing the difference between social insurance and social assistance at greater length in chapter 89.

~~24.84~~24.87 The definition of social benefits includes the possible provision of health and education services. Typically general government makes such services available to all members of the community without requiring participation in a scheme or qualifying requirements. These services are treated as social transfers in kind and not as part of social security or social assistance. Social transfers in kind are also discussed in chapter 89.

~~24.85~~24.88 In addition to health and education services provided by general government, such services may also be provided to individuals by NPISHs. These also are treated as social transfers in kind and not as part of social insurance schemes.

### 3. Social benefits provided by other institutional units

~~24.86~~24.89 Social benefits may also be provided by employers to the employees and their dependents or may be provided by other units such as a trades union. Collective arrangements that provide social benefits may also be set up for selected groups of self-employed persons. All social benefits provided by units other than general government are made under a social insurance scheme.

### 4. Social insurance schemes

~~24.87~~24.90 A social insurance scheme is a form of contractual insurance scheme where the policyholder is obliged, or encouraged, to insure against certain contingencies by the intervention of a third party. For example, government may oblige ~~all~~ employees or self-employed persons, which may include persons temporarily without employment, to participate in a social security scheme; employers may make it a condition of employment that employees participate in an insurance scheme specified by the employer; an employer may encourage employees to join a scheme by making contributions on behalf of the employee; ~~or~~ a trades union may arrange advantageous insurance cover available only to the members of the trades union; or a separate institutional unit may be established to manage a collective arrangement for selected groups of self-employed persons (see paragraph 24.100). Contributions to social insurance schemes are usually paid by, or on behalf of employees, though under certain conditions persons temporarily without employment~~non-employed~~ or self-employed persons may also be covered.

~~24.88~~24.91 *A social insurance scheme is an insurance scheme where the following two conditions are satisfied:*

- a. the benefits received are conditional on participation in the scheme and constitute social benefits as this term is used in the SNA; and*
- b. at least one of the three conditions following is met:*
  - Participation in the scheme is obligatory either by law or under the terms and conditions of employment of an employee, or group of employees;*
  - The scheme is a collective one operated for the benefit of a designated group of workers, whether employees ~~es~~ or self-employed persons, which may also include persons temporarily without employment, or non-employed, participation being restricted to members of that group;*
  - An employer makes a contribution (actual or imputed) to the scheme on behalf of an employee,*

*whether or not the employee also makes a contribution.*

The second of these conditions implies that employer-independent schemes established specifically to provide social benefits for groups of self-employed persons may qualify as social insurance schemes; see paragraph 24.100 for a further elaboration.

~~24.89~~24.92 Those participating in social insurance schemes make contributions to the schemes (or have contributions made on their behalf) and receive benefits. Contributions and benefits are defined in similar ways to insurance premiums and claims. *A social insurance contribution is the amount payable to a social insurance scheme in order for a designated beneficiary to be entitled to receive the social benefits covered by the scheme. A social insurance benefit is a social benefit payable because the beneficiary participates in a social insurance scheme and the social risk insured against has occurred.*

~~24.90~~24.93 Social security is a form of social insurance scheme. The relative importance of social security relative to other social insurance scheme varies considerably from one country to another depending on institutional arrangements. In some countries, social security may be restricted to basic pension provision of the social safety net variety. ~~In such cases even the pension provision of general government employees may be dealt with other than via social security.~~ At the other extreme, almost all pension provision, including that accruing to employees in government, private and public enterprises as well as self-employed persons, which may include persons temporarily without employment, may be routed through social security.

~~24.91~~24.94 The two classes of social insurance schemes are:

- a. Social security,
- b. ~~Employment-related~~Other social insurance schemes ~~other than social security~~.

The ~~other social insurance schemes other than social security~~ may be managed by an employer directly on his own behalf, or by a designated institutional unit set up to provide a collective social insurance type of arrangement. Alternatively, the other social insurance scheme may be arranged with an insurance corporation as a group policy or series of policies or they may be managed by an insurance corporation in return for a fee. ~~Alternatively, the schemes may be managed by an employer directly on his own behalf.~~

## Multiemployer schemes

~~24.92~~24.95 An insurance corporation may, for a fee, agree not only to ~~administer~~manage a pension scheme but to take on the risks associated with it. This ~~can be~~is done in the context of performing this service for a number of schemes collectively under what is called a multiemployer scheme. Under many such schemes, the insurance corporation takes over the responsibility of managing the funds at its disposal so as to make sufficient funds available to meet pension liabilities and to make a surplus it can retain. If it fails to make sufficient funds available for the pension entitlements, it is then the responsibility of this firm and not the original employers, to make good the difference from its own resources.

~~24.96~~ Alternatively, special institutional units may be set up to administer multiemployer pension schemes, for which the risks associated with the scheme are shared between those participating in the scheme, be it the employers, the employees and/or the persons in retirement. Such schemes may have at some stages positive, or occasionally even negative, own funds, depending on whether the accumulated asset are higher, or lower, than the pension entitlements. Similar arrangements may exist for groups of self-employed persons, or self-employed persons may be permitted to join multiemployer schemes that are predominantly intended for employees.

~~24.93~~24.97 When government takes over the responsibility for providing pensions to large sections of the community, the social security function is in effect filling the role of a multiemployer scheme. Like the insurance corporation, the government then takes on the responsibility for any shortfall in funds to meet the pension liabilities or may be entitled to retain any surplus generated. It is often the case, though, that social security is funded on a pay-as-you-go basis so there is no question of a surplus arising and, if there is a shortfall in resources, government may have powers to change the entitlements not just relating to future employment but for the past also.

## 5. Individual insurance policies qualifying as social insurance

~~24.98~~ Many social insurance schemes are organized collectively for groups of workers so that those participating do not have to take out individual insurance policies in their own names. In such cases, there is no difficulty distinguishing social insurance from insurance taken out on a personal basis. However, some social insurance schemes may permit, or even require, participants to take out policies in their own names. Most of these individual policies that may qualify as social insurance schemes are likely to be for pension provision but it is also possible that they may cover other eventualities, for example by providing income in the case the policyholder is unable to work for a prolonged period because of ill-health.

~~24.99~~ In the case of employer-employee relationships, ~~t~~The determinants for the insurance to count as a social insurance policy, and not as an individual insurance policy, are that the benefits must be of the social benefit type (see paragraph 24.82), and an employer makes an actual or imputed contribution to the scheme on behalf of an employee. If participation to a scheme is not obligatory, but only encouraged, it can become more difficult to differentiate between social insurance type of schemes and individual insurance policies. It is clear, however, that insurance policies solely taken out by individuals would not qualify as social insurance, even if, for example, a discount is arranged for a designated group of people.

~~24.100~~ Schemes providing social benefits may also be established for groups of self-employed persons. When organized by government, as part of a broader arrangement, such schemes would typically qualify as social insurance. If government is not directly involved, the default option is to not treat such types of schemes as part of social insurance, unless the schemes are collective arrangements which provide policies, for certain industries or professions, with a strong resemblance to similar arrangements organized by employers or government. These schemes may, or may not, be encouraged by government; in the former case, this would strengthen the case for a classification as social insurance. In addition, to qualify as social insurance, generally separate institutional units should be established, which are subject to regulation or supervision in line with or similar to other social insurance schemes. In the case of pension-related schemes, an additional criterion for the qualification as social insurance is that accumulated contributions are set aside for retirement income.

~~24.94~~24.101 The premiums payable, and claims receivable, under individual policies taken out under a social insurance scheme are recorded as social contributions and social insurance benefits. Contributions to social insurance schemes are frequently paid on a monthly or even more frequent basis as they are often made directly when wages and salaries are payable.

~~24.95~~ ~~Most individual policies that qualify as social insurance schemes are likely to be for pension provision but it is possible that they may cover other eventualities, for example to provide income if the policyholder is unable to work for a prolonged period because of ill-health.~~

~~24.96~~

~~24.97~~24.102 Individual insurance policies that do not qualify as social insurance are described as individual insurance not qualifying as social insurance, or in short as other insurance. They are recorded in the accounts of the sequence of economic accounts~~SNA~~ as described in sections A to F~~part 4~~ of this chapter.

## 6. Benefits payable under social insurance schemes

~~24.98~~24.103 In the SNA, social insurance benefits and the corresponding contributions are divided between those relating to pensions and those relating to all other forms of benefit. The most important pension benefit covered by social insurance schemes is income in retirement but a number of other contingencies may be covered also. For example, pensions may be payable to widows and widowers or to people who suffer an industrial injury and are no longer able to work. All of these sorts of contingencies that give rise to payments because the main income earner is no longer able, through death or incapacity, to provide an income for himself or herself and dependants are treated as pensions.

~~24.99~~24.104 All other benefits are grouped together as non-pension benefits. The distinction between the two is important because the sequence of economic accounts~~SNA~~ recognizes liabilities for some pensions whether there are actually assets set aside to meet the entitlements or not but recognizes reserves for non-pension benefits only when these actually exist.

## I. Accounting for non-pension contributions and benefits

~~24.100~~24.105 Non-pension benefits may be payable under social security and under ~~employment-related~~other social insurance schemes~~-other than social security~~. Although in many countries there may in fact be no non-pension benefits, a description is given of how these should be recorded if they exist. For other, non-pension related, social insurance schemes, the way of recording varies depending on whether reserves for provision of future benefits are set aside or not. Although in many cases there may be no such reserves and the benefits are paid on a pay-as-you-go basis, a description of the appropriate recording in each case is given.

### 1. Non-pension benefits payable under social security

~~24.101~~24.106 As is typical of social security schemes, there may be contributions payable by both the employer and the employee. Contributions may also be payable by self-employed persons, or persons temporarily without employment. The costs of operating social security schemes are treated as part of the normal expenditure of general government and so the accounting for social security operations does not include measures of output.

~~24.102~~24.107 In the sequence of economic accounts~~SNA~~ flows are recorded as follows.

- a. Employers' social security contributions are shown as payable by the sector in which the employer is located and receivable by households. The sector of the employer may be any of non-financial corporations, financial corporations, general government (as an employer), employer households, NPISHs or the rest of the world (when a resident works for a non-resident institutional unit). For resident employers the payables are shown in the generation of earned income account; payables by non-resident employers are shown in the ~~primary distribution of earned~~ income account for the rest of the world. Receivables by resident households are shown in the allocation of primary earned income account and by non-resident households in the ~~primary distribution of earned~~ income account for the rest of the world.
- b. In the ~~secondary distribution of~~ income transfers other than social transfers in kind account, the sum of employers' social security contributions and social security contributions by households in their capacity~~ies~~ as employees or any other capacity, is shown as payable by households and receivable by government. Further, social security benefits in cash payable to households are shown as payable by government (or the rest of the world if from a foreign government) and receivable by households.

~~24.103~~24.108 An example of these flows is shown in table ~~1724~~24.3.

**Table ~~1724~~24.3: Accounts for non-pension benefits paid through social security - ~~uses~~expenditures**

**Table ~~1724~~24.3 (cont): Accounts for non-pension benefits paid through social security - ~~resources~~revenues**

### 2. Unfunded non-pension benefits other than from social security

~~24.104~~24.109 In the SNA, an employer operating an unfunded scheme is regarded as making an imputed social contribution to the scheme on behalf of the employees. In practice, the value of the employers' and employees' contributions is usually set equal in value to the benefits payable in the period under consideration (plus the cost of operating the scheme as described in the following paragraph). The imputed contribution forms part of the compensation remuneration of employees and is also shown as being payable by the employees to the scheme together with any actual payments by the employees. Even though the scheme is unfunded, the employee may still make a contribution; however, it is not uncommon for unfunded schemes to be non-contributory for the employees.

~~24.105~~24.110 Even if a scheme is unfunded, there are costs involved in administering it. In principle, output equal to the sum of these costs should be treated as being paid for by the beneficiaries from an imputed element of contributions. The imputed contribution to employees should include these costs as well as the value of the benefits received by employees. A value equal to the amount of the costs of operating the scheme is then recorded in the use of income account as a purchase of a service by the employees from the employer.

~~24.106~~24.111 There are two transactions recorded for the production and consumption of the services provided by the employer. Because the scheme is unfunded, there are no investment income flows and no contribution supplements to be recorded. There are two sets of redistributive transactions recorded.

~~24.107~~24.112 The production and consumption transactions are as follows.

- a. Output of services is imputed in the production account of the employer and the value of the output forms part of the imputed employers' contributions to social insurance incorporated in ~~compensation~~remuneration of employees.
- b. Consumption of the service is recorded as household final consumption expenditure in the use of income account for resident households or as exports for non-resident households.

~~24.108~~24.113 The redistributive transactions are as follows.

- a. Employers' imputed contributions to unfunded social insurance schemes are shown as a payable by the sector in which the employer is located in the generation of earned income account and a receivable by households in the allocation of ~~primary~~earned income account.
- b. In the ~~secondary distribution of income~~ transfers other than social transfers in kind account, employers' imputed contributions and any actual contributions by employees are shown as payable by households and receivable by the employer. Further, benefits payable to households by the employer are shown as payable by the employer and receivable by households.

~~24.109~~24.114 An example of these flows is shown in table ~~1724~~4.

**Table ~~1724~~4: Accounts for non-pension social insurance benefits from unfunded other employment-related schemes - ~~uses~~expenditures**

**Table ~~1724~~4 (cont): Accounts for non-pension social insurance benefits from unfunded other employment-related schemes - ~~resources~~revenues**

### 3. Funded social insurance other than pensions

~~24.110~~24.115 As noted above, funded schemes for benefits other than pensions are not very common. They may, however, exist in two circumstances. The first is when an employer has a fund for such benefits and accumulates any underspend in one year to pay for possible overspends in future years. Alternatively, an employer may realize that the commitments to make payments in future are such that it is prudent to build reserves to be able to make such payments. An example of such a scheme might be one that provides health cover to present and past employees. Unlike in the case of pensions, estimates of possible future claims on social insurance benefits other than pensions are not necessarily included in the SNA. Liabilities are recorded only when and to the extent that they exist in the employer's accounts.

~~24.111~~24.116 Funded social insurance covering benefits other than pensions for employees, including persons temporarily without employment, may be carried out by insurance corporations or by employers on behalf of their employees. Separate units may also be established for administering a scheme for self-employed persons. The output of this activity is measured in the same way as the output of non-life insurance but the matching consumption of the services is payable only by the households of the beneficiaries. These will be resident households except where a resident producer is liable to pay benefits to a present or former employee who is a non-resident or who has a non-resident family member entitled to the benefits. The investment income attributed to the beneficiaries of the social insurance schemes can only be receivable by the same households.

~~24.112~~24.117 Employers' contributions relate only to employees. However, both current and former employees who are now, or may in future be, beneficiaries may make contributions to the scheme and receive investment income from it. This investment income is then treated as contribution supplements payable by those receiving it.

~~24.113~~24.118 All contributions to the schemes are recorded as payable by households. These contributions include that part paid by the employer as part of ~~compensation~~remuneration of employees in the generation of earned income

account as well as contributions paid directly by the employee funded from wages and salaries or by others including former employees and self-employed persons. Further, households receive investment income attributable to policyholders in respect of these contributions and this is treated, in total, as contribution supplements. Two items of contributions appear in the ~~secondary distribution of income~~ transfers other than social transfers in kind account. The first, the employers' actual social contributions, is exactly equal in value to the amount receivable by households from the employer in the generation of earned income account. The second item, called households social contributions, includes the direct payment by households, including those paid by former employees and self-employed persons, plus the contribution supplements less the service charge payable to the social insurance schemes.

~~24.114~~24.119 Eight transactions must be recorded, ~~one each~~two relating to production and consumption of the insurance service, three relating to contributions and benefits, one to the investment income attributable to policyholders and two relating to the difference between contributions and benefits:

- a. The activity by resident units is undertaken by an insurance corporations, ~~or~~ by an employer, or by a unit specifically established for administering a scheme; the output is recorded in the production account of the insurance corporations or in the sector of the employer as appropriate;
- b. Employers' actual social contributions to employment-related social insurance schemes are shown as payable by the sector in which the employer is located in the generation of earned income account and receivable by households in the allocation of primary earned income account;
- c. Investment income attributed to policyholders (beneficiaries) in respect of these schemes is payable by insurance corporations and employers, and receivable by households. Both payables and receivables are recorded in the allocation of primary earned income account;
- d. ~~Net~~Social contributions less service charges are shown in the ~~secondary distribution of income~~ transfers other than social transfers in kind account as payable by households and receivable by insurance corporations or the sector of the employer as appropriate;
- e. ~~Employment related~~Other social insurance non-pension benefits ~~other than pensions~~ are also shown in the ~~secondary distribution of income~~ transfers other than social transfers in kind account as payable by insurance corporations or the sector of the employer and receivable by households;
- f. The value of the service is payable by households as part of final consumption expenditure and is recorded in the use of income account, except for non-resident employee households where it is payable by the rest of the world;
- g. The excess of ~~net~~ contributions less serviced charges over benefits represents an increase in the liability of the insurance scheme towards the beneficiaries. This item is shown as an adjustment in the use of income account. As an increase in a liability, it is also shown in the financial account. As noted, the item is likely to occur only rarely and, for pragmatic reasons, changes in such non-pension entitlements may be included with those for pensions.

~~24.115~~24.120 An example of these flows is shown in table ~~1724~~24.5.

**Table ~~1724~~24.5: Accounts for non-pension social insurance benefits from funded other employment-related schemes - ~~uses~~expenditures**

**Table ~~1724~~24.5 (cont): Accounts for non-pension social insurance benefits from funded other employment-related scheme - ~~resources~~revenues**

## J. Accounting for pension contributions and pensions

~~24.116~~24.121 Pensions are provided to individuals in an economy under one of three mechanisms, via social security, via employment-related other social insurance schemes ~~other than social security~~ or via social assistance. Together, social security and employment-related other social insurance pension schemes ~~other than social security~~ constitute social insurance schemes. Although the benefits provided under social assistance and some social insurance schemes may be very similar, the key distinction is that social insurance benefits are only paid if

the beneficiary participates in the social insurance scheme, participation being normally evidenced by the beneficiary or another on his behalf having made qualifying contributions. Social assistance is paid without qualifying contributions having been made though means-testing may be applied to applicants.

~~24.117~~24.122 The means by which pensions are provided to persons in retirement varies considerable from one country to another. This ~~section~~~~part of chapter 17~~ describes the most common forms of pension provision made under social insurance schemes though not all aspects may apply to all countries. Pensions provided under social assistance are not discussed in this chapter but in chapters ~~89~~ and ~~910~~.

~~24.118~~24.123 Social insurance pensions in all countries are provided, if at all, in part by general government and in part by employers. ~~They may also relate to collective arrangements for self-employed persons (see paragraph 24.100).~~ The part provided by general government (~~other than certain schemes provided by government in its role as an employer~~) is called social security and the ~~part by employers~~~~remainder~~ is called ~~employment-related~~~~other social insurance~~ schemes ~~other than social security~~. The division between which pensions are provided by social security and which by other ~~employment-related~~~~social insurance~~ schemes varies considerably from country to country with the consequence that the coverage and therefore national perceptions of what the term “social security” designates also vary considerably. In order to make clear the recommendations in the SNA, it is necessary to consider the types of coverage provided in different countries.

~~24.119~~24.124 The narrowest form of social security pension is very basic. The level may be fixed independently of the size of contributions (though not of the fact that contributions have been made for a given period of time). ~~In the case of employer-employee types of arrangements,~~ ~~A~~an employee’s right to a pension under social security is often transferable (“portable”) from one employer to another, which is an advantage not always applying to other pension provisions, but for many people in low paid jobs, working temporarily or intermittently, it may be the only form of pension provision they can expect to receive.

~~24.120~~24.125 ~~By contrast, i~~In some countries most or all pension provision may be made via social security. In this case, government acts as an intermediary relative to the employer, ~~or self-employed person~~, so that once the government has received the contributions to the scheme paid by the employer and the households, the government then takes on the risk of making the eventual payment. Government relieves the employer, ~~or the self-employed person~~, of the risk that the cost of pensions may be too great ~~for his enterprise~~ to meet and assures the population that pensions will be paid, though it may do so with the qualification that it may alter the amount of pensions payable, even retrospectively, if economic conditions so dictate.

24.126 Pension schemes ~~derived from an employer-employee relationship, including those~~ run by ~~private~~public employers, are usually not subject to retrospective adjustments of the amounts payable, but there is a risk that the employer may be unable to pay because he has gone out of business. Increasingly, though, protection for the pension entitlements of individuals is becoming more common. Equally, the pension built up with one employer may not be transferable to a new employer though this too is undergoing change. While social security may be, and very often is, financed on a pay-as-you-go basis, without building up reserves for future liabilities, other ~~employers~~social insurance schemes are increasingly likely to have reserves set aside. Even if there are no reserves, accounting conventions may require ~~employers~~them to recognize pension entitlements of present and past employees in their accounts.

~~24.121~~24.127 When it comes to the recognition of pension entitlements, entitlements related to social security type of schemes are typically not recognised as assets (and liabilities) in the sequence of economic accounts, while entitlements derived from an employer-employee relationship are recognized as such. The main reason for treating the latter entitlements as assets is that they are usually not subject to retrospective adjustments of the amounts payable. The entitlements can be regarded as part of the conditions of employment, whereas social security schemes are generally imposed by law. The legal nature of the employment contract underlying the scheme significantly limits the possibility of the manager, be it a private employer or a public employer, to change the basis on which entitlements are determined. This assumes that the conditions of employment are the same, or at least sufficiently similar, for employees of private and public employers. If this is indeed the case for schemes for public employees, the related entitlements would qualify as assets (and liabilities) in the sequence of economic accounts, most certainly if the schemes are clearly separated from the social security type of pension schemes. In certain circumstances, defining similarity may not be that straightforward. A public employment contract may not follow the same terms as a private employment contract. The former type of contracts may be more generous in some aspects (e.g., tenure) but more restrictive in other aspects (e.g., ability to join political groups). Moreover, in some countries, public employees are governed by a general law, not by individual employment contracts. In

such cases, where there are separate schemes for public employees, the concept of similarity should first and foremost focus on the terms and conditions of compensation, both current compensation and future compensation after retirement.

~~24.122~~24.128 Employment-related pensions, other than the most basic form of social security, are seen as part of the compensation package and negotiations between employees and employers may focus on pension entitlements as much as on current conditions of service and pay scales. Often pensions are provided by ~~private~~ employers from funds that the employers control or contract to a third party such as an insurance corporation, or another unit specifically established to administer the scheme. These funds may also provide social benefits other than pensions, for example private medical coverage. It is sometimes possible for a specialized unit to agree to assume responsibility for providing pensions for a number of employers in return for assuming the risk of ensuring adequate funding is available to make the promised pensions. Such an arrangement is called a multiemployer pension scheme; see also paragraphs 24.95 to 24.97.

~~24.123~~24.129 As with non-pension social benefits, ~~both current employees, and former employees and self-employed persons~~, who are current or future beneficiaries may make contributions to the scheme and receive investment income from it. This investment income is then treated as contribution supplements by those receiving it.

## 1. Social security pensions

~~24.124~~24.130 It is common but not essential for both employers and employees to make contributions towards a social security pension. In addition, contributions may be made by self-employed persons and persons temporarily without employment. It is also common for the contributions to be compulsory. Social security pensions are frequently funded on a pay-as-you-go basis. The normal assumption in the ~~mainsequence of economic~~ accounts of the SNA is that this is how social security pensions are funded. That is the contributions receivable in a period are used to fund the benefits payable in the same period. There is no saving element involved, either for the government operating the scheme or for the individuals participating in it. No liabilities for the scheme are recognized in the ~~mainsequence of economic~~ accounts of the SNA although concern is often expressed that benefits may exceed contributions and this situation is likely to worsen in an ageing population. For this reason, estimates of the liabilities of social security as well as any other pension schemes not included in the ~~mainsequence of economic~~ accounts are included in a supplementary table described below in section Jxx.

~~24.125~~24.131 The recording of the flows for social security pension schemes is simple. Any contribution made by the employer is treated as part of ~~compensation~~remuneration of employees. It is recorded as payable by the employer in the generation of earned income account and receivable by the employee in the ~~distribution of primary allocation of earned~~ income account. The employee then pays an amount equal to what he receives from the employer together with any contribution he is liable to make on his own behalf to the social security fund. This amount is recorded as payable by households in the ~~secondary distribution of income~~ transfers other than social transfers in kind account and receivable by the government in the same account. Any contributions made by self-employed ~~persons or persons temporarily without employment~~non-employed people are also included with the contributions payable by households to government. Social security benefits are also recorded as payable by government and receivable by households in the ~~secondary distribution of income~~ transfers other than social transfers in kind account.

~~24.126~~24.132 An example of these flows is shown in table ~~1724~~1724.6. It is similar in content to table ~~1724~~1724.1 except that table ~~1724~~1724.1 relates to non-pension benefits and table ~~1724~~1724.6 to pension benefits.

Table ~~2417~~1724.6: Accounts for pension benefits paid through social security - ~~uses~~expenditures

Table ~~1724~~1724.6 (cont): Accounts for pension benefits paid through social security - ~~resources~~revenues

## 2. ~~Employment-related~~Other social insurance pension schemes ~~other than social security~~

~~24.127~~24.133 There are two forms of ~~employment-related~~other social insurance pension schemes ~~other than social security~~. One is called a defined contribution scheme, sometimes referred to as a money purchase scheme. ~~(The expression “defined contribution pension scheme” is not intuitive but is widely used in the pension industry.)~~ The other is a defined benefit scheme, for which the benefits are typically based on salaries earned during employment

~~and the years of service sometimes referred to as a final salary scheme, though this term does not accurately describe all defined benefit schemes.~~ Typically both schemes are contributory, in the case of schemes derived from an employer-employee relationship often by both the employer and the employee.

~~24.128~~24.134 *A defined contribution scheme is one where the benefits payable to an employee, or self-employed person, on retirement are defined exclusively in terms of the level of the fund built up from the contributions made over the employee's working life and the increases in value that result from the investment of these funds by the manager of the scheme. The entire risk of the scheme to provide an adequate income in retirement is thus borne by the employee, or self-employed person.*

~~24.129~~24.135 *A defined benefit scheme is one where the benefits payable to an employee, or a self-employed person, on retirement are determined by the use of a formula, either alone or as a minimum amount payable.* In this case the risk of the scheme to provide an adequate income in retirement is either borne entirely either by the employer or is shared between the employer(s), the and employees, or self-employed persons, and the retired persons. In certain cases, the employer's risk may be borne by the multiemployer scheme that operates the defined benefit pension scheme on behalf of the employer. A scheme that may be defined in terms similar to a defined contribution scheme but with a guaranteed minimum, say, or other such hybrid schemes are grouped with defined benefit pension schemes in the SNA. Notional defined contribution schemes are also grouped with defined benefit schemes.

~~24.130~~24.136 For both types of schemes, pension entitlements of the participants are recorded as they build up. In both cases, there is investment income earned on existing entitlements and this is recorded as being distributed to the beneficiaries and reinvested by them in the pension scheme. There are, though, a number of different features of the two schemes, so the transactions relating to each are described in detail separately before turning to other changes in the levels of pension entitlements. The recording of transactions for a defined contribution scheme is less complicated than the defined benefit scheme and is described first.

~~24.131~~24.137 ~~For both types of schemes, a pension fund is assumed to exist.~~ For a defined contribution pension scheme, a fund must exist. For ~~a~~ defined benefit pension schemes, there are three cases: (i) a fund of accumulated assets may exist and is sufficient to cover the pension entitlements (fully funded) in reality; (ii) a fund of accumulated assets exists, but is insufficient to meet the pension entitlements (partially funded); or (iii) or it may be a notional no fund exists (unfunded). If ~~it~~ a fund exists, it may be part of the same institutional unit as the employer, it may be a separate institutional unit (an autonomous pension fund ~~scheme~~) or it may be part of another financial institution, either an insurance corporation or a multiemployer pension scheme. In describing the recording of transactions, transactions with the pension fund must be attributed to the sector where the fund is located.

## Defined contribution pension schemes

~~24.132~~24.138 Recording the transactions related to a defined contribution pension scheme presents no conceptual problems. There are no associated imputations either for the flows concerned or for the values appearing in balance sheets for the pension entitlements of the beneficiaries nor any doubt as to which unit has a liability and which an asset.

### *Transactions recorded for a defined contribution pension scheme*

~~24.133~~24.139 The contribution made by an employer to a defined contribution pension scheme on behalf of his employee is treated as part of compensation remuneration of employees. It is recorded as payable by the employer in the generation of earned income account and receivable by the employee in the distribution of primary earned income account.

~~24.134~~24.140 The investment income on the cumulated pension entitlements is also recorded as being distributed to (receivable by) households in the allocation of earned primary income account and is shown as payable by the pension fund. The investment income includes interest and dividends payable plus the distributed income of collective investment schemes if the pension fund holds shares in them. It is possible that the pension fund may own property and generate net operating surplus on this which is also included along with the investment income as being distributed to the pension beneficiaries. In this case, the term investment income is to be interpreted as

being elastic enough to include this source of income if it exists. Holding gains and losses generated by the investment of the cumulated pension entitlements are not included in investment income.

~~24.135~~24.141 Part of the income distributed to households is used to meet the costs of operating the pension fund. This cost is shown as the output of the pension fund in the production account and as an element of consumption expenditure by households in the use of income account. The remaining part of the distributed income is treated as pension contribution supplements paid back by households to the pension funds.

~~24.136~~24.142 In the ~~secondary distribution of income~~ transfers other than social transfers in kind account, social contributions are shown as payable by households and receivable by the pension fund. The total amount of the social contributions payable is made up of the actual contributions payable by the employers as part of ~~compensation remuneration~~ of employees, actual contributions by employees and possibly by other individuals (individuals formerly participating in a scheme, self-employed and non-employed persons as well as retirees) plus the contribution supplements just specified. For clarity, and to enhance the comparison with defined benefit schemes, the supplements are shown at full value in both the allocation of ~~earned primary~~ income account where they appear as investment income and in the ~~secondary distribution of income~~ transfers other than social transfers in kind account where they appear as contribution supplements. However, the service charge is shown as an offsetting negative element to total household contributions in the ~~secondary distribution of income~~ transfers other than social transfers in kind account. The total contributions made by households to the pensions scheme are ~~not adjusted for the service charges~~ in the same way that direct insurance premiums are ~~not adjusted~~, that is to say they are the total of all contributions made less the service charge appearing in the use of income account.

~~24.137~~24.143 Those other than employees who contribute to a defined contribution pension scheme may be self-employed persons participating in a defined contribution pension scheme or may be persons not employed who participate in a defined contribution pension scheme by virtue of their profession or former employment status, for example.

24.144 Also in the ~~secondary distribution of income~~ transfers other than social transfers in kind account, the pension benefits payable to households by the pension fund are shown. However, the benefits payable under a defined contribution pension scheme take the form of a lump sum payable at the moment of retirement. It may be a requirement of the scheme that these sums are to be immediately converted to an annuity with the same or another financial institution but this is not a universal requirement. The appropriate recording of the benefits is not to show the benefit as payable immediately on retirement and then, where appropriate, reinvested in terms of an annuity or other forms of financial assets but to record the transfers of the entitlements and related assets as financial transactions. Any difference between the transfer of entitlements and the transfer of related assets is to be recorded as a capital transfer between the pension scheme and the unit providing the annuity, notionally as a reclassification from life insurance entitlements to annuities entitlements. However, since no distinction is normally made between these two sets of entitlements, no actual classification change will show in the accounts. In this respect, it is also important to note that the benefits from such an annuity continue to be recorded as pension benefits. For more information on the transfer of entitlements, see paragraphs 24.196 to 24.200. In case the benefits become payable in the form of a lump sum, and the subsequent investment into an annuity (or another form of investment) is an individual decision, the lump sum would be recorded as pension benefits, followed by the purchase of a (individual) life insurance contract. The recording of annuities is discussed in ~~part I~~ section D of this chapter.

~~24.138~~24.145 In the use of income account, there is an entry for the payment of the service provided by the pension fund (equal to the value of the pension fund's output) payable by households to the pension fund.

~~24.139~~24.146 In the same account there is an entry showing the increase (or decrease) in pension entitlements caused by the excess (or deficit) of contributions payable less benefits receivable in the ~~secondary distribution of income~~ transfers other than social transfers in kind account. This amount is shown as payable to households by the pension fund. Because much of the increase in the pension entitlement of participants in a defined contribution pension scheme, and thus ultimately the funding for the benefits, come from holding gains that are not included in the contribution supplements of participants in defined contribution pension schemes, the adjustment for the change in pension entitlements for these individuals will frequently be negative.

~~24.140~~24.147 The adjustment for the change in pension entitlements that is included in the use of income account as payable by the pension fund to households is shown in the financial account as payable by households to the pension fund. The effect of any transfer of the obligations to meet pension entitlements from a unit in one sector

to another are also reflected in the financial account item.

~~24.141~~24.148 The other factors affecting the change in the balance sheet entry for the change in pension entitlements are shown in the other changes in assets accounts. In particular, the liabilities of the scheme to the beneficiaries show holding gains or losses in the revaluation account corresponding exactly to those on the assets held by the scheme to meet these obligations. ~~When payments under a defined contribution scheme are made via annuities, other volume changes may need to be recorded as explained in paragraph 17.136.~~

~~24.142~~24.149 Table ~~1724.7~~ illustrates the entries necessary to record the transaction related to a defined contribution scheme. It is simpler than the corresponding table for a defined benefit scheme, which is described in the following section, because of the absence of any imputed transactions.

**Table ~~1724.7~~: Accounts for pension benefits payable under a defined contribution scheme - ~~uses~~ expenditures**

**Table ~~1724.7~~ (cont): Accounts for pension benefits payable under a defined contribution scheme - ~~resources~~ revenues**

## Defined benefit pension schemes

### *Differences between a defined benefit and a defined contribution pension scheme*

~~24.143~~24.150 The fundamental difference in accounting for a defined benefit pension scheme as compared with a defined contribution pension scheme is that, for the defined benefit pension scheme, the benefit to the employee in the current period is determined in terms of the undertakings made by the employer about the level of pension ultimately receivable, whereas for the defined contribution pension scheme the benefit to the employee in the current period is determined entirely by the contributions made to the scheme and the investment income and holding gains and losses earned on these and previous contributions. Thus while there is (in principle) exact information available on the ~~benefits~~ pension entitlements accrued to date by for the participants in a defined contribution pension scheme, the ~~benefits~~ pension entitlements accrued to date by for the participants in a defined benefit pension scheme must be estimated. The source of these estimates is the actuarial estimates drawn up by the employer ~~or other institutional unit administering the scheme is faced with in drawing up his own accounts.~~

~~24.144~~24.151 There are four sources of changes in pension entitlements in a defined benefit pension scheme. The first of these, the current service increase, is the increase in entitlements ~~resulting from the employee service associated with the wages and salaries earned~~ in the current period. The second source, ~~the past service increase~~, is the increase in the value of the entitlement due to the fact that for all participants in the scheme, retirement (and death) are one year nearer. The third change in the level of entitlement is a decrease due to the payment of benefits to retirees of the scheme. The fourth source of change comes from ~~the past service increase, which is the change in the present value of the pension entitlement for employee service in prior periods resulting from scheme amendments or curtailments, and other factors, factors that are reflected in the other changes in assets account.~~

~~24.145~~24.152 As with a defined contribution pension scheme, both employer and employee may make actual contributions to the scheme in the current period. However, these payments may not be sufficient to meet the increase in the benefits accruing from the current year's employment. Therefore an additional contribution from the employer is imputed to bring equality between the contributions and the increase in current service entitlements. These imputed contributions are usually positive but it is possible for them to be negative if the sum of the contributions received exceeds the increase in current service entitlements. The implications of this case are discussed below when examining the relationship between the employer and the fund.

~~24.146~~24.153 At the end of an accounting period, the level of the pension entitlements due to past and present employees can be calculated by estimating the present value of the amounts due to be paid in retirement using actuarial estimates of the expected life length of the beneficiaries. This is the amount that appears in the balance sheet as the liability towards the employees. One element in the increase of this amount year by year is the fact that the present value of the entitlements existing at the beginning of the year and still due at the end of the year have increased because the future is one year nearer and so one fewer discount factor must be used to calculate the present value. It is this unwinding of the discount that accounts for the ~~investment income earned by the pension beneficiaries~~ past service increase in entitlements.

~~24.147~~24.154 A further basic difference between a defined benefit pension scheme and a defined contribution pension scheme concerns the payment for the cost of operating the pension scheme. As already noted, under a defined contribution pension scheme all the risk is borne by the beneficiaries. The pension scheme is operated on their behalf and they pay for the cost of it. Since the fund may be operated by a unit other than the employer, it is appropriate to treat the operating cost as part of the investment income that is retained by the fund to meet its costs (and generate a profit). In keeping with accounting for insurance, the investment income is treated as being attributed in full to the beneficiaries, part being used to meet the cost and the remainder being reinvested with the fund.

~~24.148~~24.155 For a defined benefit pension scheme, the situation is somewhat different. The risk that the fund may be insufficient to meet the promises of entitlement is met in part or in whole by the pension manager (either the employer or a unit that has assumed the risk of meeting the pension obligations, often referred to as the pension sponsor) and not by the beneficiaries alone. The fund may be directly controlled by the employer and be part of the same institutional unit or may be purely notional. Even in this case, there are costs associated with operating the scheme. Although these are initially borne by the employer, it is appropriate to regard this as a form of income in kind provided to the employees and for convenience it may be included with the employers' contributions. There is an element of pragmatism in this since this assumes all the costs are borne by current employees and none by retirees. It also assumes that the attribution that must be made in the case of notional schemes can be applied in other circumstances also.

~~24.149~~24.156 For a defined benefit scheme, it is unlikely that self- and non-employed persons currently contribute though it is possible if they were previously in employment giving rise to a defined benefit pension and have the right to continue to participate. Those previously in employment (whether currently in receipt of a pension or not) receive investment income and pay contribution supplements.

### *Transactions recorded for a defined benefit pension scheme*

~~24.150~~24.157 The initial discussion assumes that the employer retains the whole responsibility for meeting the pension payments. Alternatives involving the use of a multiemployer scheme or where government assumes responsibility on behalf of the employer are discussed subsequently.

24.158 The total contribution made by an employer to a defined benefit pension scheme on behalf of his employee must be sufficient that, together with any actual contribution by the employee and excluding the cost of operating the scheme, it exactly matches the current service increase in the employee's pension entitlements. The contribution by the employer is divided into an actual and an imputed part, the latter being calculated so as to meet the need of an exact match between all contributions to the fund adding to the entitlements of the employee and the current service cost of these entitlements.

~~24.151~~24.159 The contribution by the employer should be calculated in relation to the pension entitlements earned in the period regardless of any investment income earned by the scheme in the same period or any overfunding of the scheme. The current period entitlement is part of compensationremuneration of employees and not to include the full value of the employer's contribution understates compensationremuneration of employees and therefore overstates operating surplus. An extreme case has occurred in the past when the investment of the pension entitlements has done so well that the employer has taken a "contribution holiday", that is he has not made an actual contribution towards new entitlements. It is important that contributions continue to be recorded even in the event of a contributions holiday, the benefit to the employer being regarded as a change in liabilities between the pension fund and the employer. This leaves the net worth of both the same as when contributions are not recorded under a contributions holiday without reducing compensationremuneration of employees artificially.

~~24.152~~24.160 Under many defined benefit schemes, there is a qualifying period before an employee does in fact become eligible to receive a pension in retirement. Despite this qualifying period, both contributions and entitlements should be recorded from the start of employment adjusted by a factor reflecting the probability that the employee will in fact satisfy the qualifying period.

~~24.153~~24.161 The sum of employers' actual and imputed pension contributions is treated as part of compensationremuneration of employees. It is recorded as payable by the employer in the generation of earned income account and receivable by the employee in the allocation of primaryearned income account.

~~24.154~~24.162 The increase in the present value of the entitlements of continuing employees and those who no longer contribute but remain eligible for pensions in future ~~(the past service increase)~~ represents the investment income distributed to the employees. No deduction is made for any amount that may be funded from holding gains or that is not actually matched by existing funds. It matches the amount that is unequivocally due to the employee under the prevailing agreements; the means by which the employer may ultimately match this obligation is not relevant for the recording of this as investment income any more than the means by which interest or dividends are actually financed affect their recording as investment income. The investment income is recorded as payable by the pension fund and receivable by households. It is immediately reinvested by the households in the fund and in this guise is described as pension contribution supplements.

24.163 Especially in the case of (significantly) underfunded schemes, the income earned on the accumulated assets may fall short of the investment income payable on pension entitlements. On the other hand, there may be schemes where the income earned from accumulated assets is in excess of the investment income payable on pension entitlements. The shortfall (or excess) in investment income receivable by the pension fund is treated as an imputed investment income attributable to surplus/shortfall in defined benefit pension funds. This income flow is recorded as a (negative) payable and a (negative) receivable between the pension manager (i.e., the sponsor of the pension scheme) and the pension fund. As a result, the income related to the unwinding of the entitlements exactly matches the income earned on the accumulated assets plus the imputed income from the pension manager.

~~24.155~~24.164 In the ~~secondary distribution of income~~ transfers other than social transfers in kind account, social contributions are shown as payable by households and receivable by the pension fund. The total amount of the social contributions payable is made up of the actual and imputed contributions payable by the employers as part of ~~compensation remuneration~~ of employees (excluding the amount of the costs of running the pension scheme), plus actual contributions by employees, plus the contribution supplements ~~just~~ specified in paragraph 24.162. As explained in the discussion under defined contribution schemes, the accounts show the full value of the contributions and contribution supplements with an offsetting item representing the service charge payable. ~~The amount actually payable is thus a net contributions figure.~~

~~24.156~~24.165 Also in the ~~secondary distribution of income~~ transfers other than social transfers in kind account, the pension benefits payable to households by the pension fund are shown. When the benefits are taken in terms of an annuity, it is the annuity payments that are shown here, not the lump sums payable at the time of retirement. ~~(Unless the demographics of the retirees changes dramatically, the two figures will be very similar in any case.)~~

~~24.157~~24.166 In the use of income account, there is an entry for the payment of the service provided by the pension fund (equal to the value of the pension fund's output plus the output of the enterprises operating annuities bought with pension entitlements) payable by households to the pension fund and recorded as final consumption expenditure.

24.167 Also in the use of income account, there is an entry showing the increase (or decrease) in pension entitlements caused by the excess of contributions payable less benefits receivable in the ~~secondary distribution of income~~ transfers other than social transfers in kind account. This amount is shown as payable to households by the pension fund. In the case of a defined benefit pension scheme, the amount is unlikely to be negative unless it is a scheme for a defunct employer and it is only paying benefits and not receiving new contributions.

~~24.158~~24.168 The value of defined benefit pension entitlements may also be affected by changes in the terms of entitlements, mainly impacting past service costs. If these changes in terms are the result of negotiations between the employer (pension manager, often referred to as the pension sponsor) and beneficiaries, for example via a trade union, or the result of a legislative act, for instance on pension reforms for public sector employees, in which the 'negotiation' is deemed to have taken place via the discussion by members of the legislature, the changes in entitlements should be recorded as capital transfers from the beneficiaries to the pension scheme, and subsequently as a capital transfer from the pension scheme to the pension manager.

~~24.159~~24.169 The same amount that is included in the use of income account as the adjustment for the change in pension entitlements plus the changes in entitlements as a result of negotiations about the terms are included in the financial account as a change in the claim by households on the pension fund. ~~(The other part of this item reflects any change in responsibility for pension entitlements recorded as part of capital transfers.)~~ The other factors affecting the change in the balance sheet entry for the change in pension entitlements are shown in the other changes in assets accounts and are discussed further below ~~in section 4~~.

### *Defined benefit pension schemes operated by other than employers*

~~24.160~~24.170 It is possible that some other organization, such as a trades union, may operate a defined benefit pension scheme for its members that is in all respects parallel to an employer's defined benefit pension scheme. Exactly the same recording is followed as just described except that references to the employer should be understood to refer to the scheme organizer and references to the employee should be understood to refer to the participant in the scheme.

### *The relationship between the employer and the pension fund*

~~24.161~~24.171 As noted above, an employer may contract with another unit to administer the pension ~~scheme~~~~fund~~ and arrange disbursements to the beneficiaries. There are two ways in which this may happen. The operator of the pension ~~scheme~~~~fund~~ may simply act as the employer's agent and the responsibility for any shortfall in the fund (or the benefit of any excess) remains with the employer. In this case the unit handling the day to day running of the pension ~~scheme~~~~fund~~ is called the pension administrator.

24.172 However, it is not uncommon for a single unit to contract with several employers to manage their pension ~~schemes~~~~funds~~ as a multiemployer pension ~~scheme~~~~fund~~. The arrangements are such that the multiemployer pension ~~scheme~~~~fund~~ accepts the responsibility for any shortfall in the funds to meet the liabilities in return for the right to keep any excess funds. By pooling the risks over a number of employers the multiemployer fund expects to balance under- and over-funding so as to emerge with an excess over all the funds taken as whole in a similar way that an insurance corporation pools risk for many clients. In such a case, the unit assuming responsibility for meeting the pension obligations becomes the pension manager in place of the employer.

24.173 Alternatively, as noted in paragraph 24.96, special institutional units may be set up to administer a multiemployer pension scheme, for which the risks associated with the scheme are shared between those participating in the scheme, be it the employers, the employees and/or the persons in retirement. Such schemes may have at some stages positive, or occasionally even negative, own funds, depending on whether the accumulated asset are higher, or lower, than the pension entitlements. Similar arrangements may exist for groups of self-employed persons.

~~24.162~~24.174 In the case where the employer retains the liability for any underfunding or the benefit of any overfunding, a (negative) claim on ~~(or liability towards)~~ the employer (the pension manager) by the pension fund should be recorded for any deficit or surplus. The change in this claim is equal to the difference between the increase in pension entitlements and the sum of the contributions and contributions supplements in the period, plus the investment income earned on the entitlements, plus the holding gains made on them, less the pensions payable, less the fee charged by the pension administrator. When the amount accruing to the pension fund exceeds the increase in entitlements, there is an amount payable by the pension fund to the employer as pension manager. In this way the net worth of the pension fund remains exactly zero at all times.

~~24.163~~24.175 The amount due to the pension manager by the pension fund is where the impact of a contribution holiday shows up since it includes the amount of the employer's contributions that would normally be payable.

### **A numerical example**

#### *Transactions for ~~a~~ defined benefit schemes operated by other than employers*

~~24.164~~24.176 In order to illustrate the recording of transactions connected with a defined benefit pension scheme, table ~~17~~24.8 shows a numerical example. Figures that are imputed are shown in bold; those that result from re-routing are shown in italics.

**Table 17.8: Accounts for pension benefits payable under a defined benefit scheme - ~~uses~~expenditures**

**Table ~~17~~24.8 (cont): Accounts for pension benefits payable under a defined benefit scheme - ~~resources~~revenues**

~~24.165~~24.177 Actuarial calculations show that the increase in pension entitlement coming from current service, that is the pension “earned” in the year in question is 15. Households (the employees) contribute 1.5. The employer therefore is obliged to provide 13.5. In addition the cost of operating the scheme is estimated at 0.6. In total therefore the employer must provide 14.1. He actually contributes 10 so the remaining 4.1 is an imputed contribution. The output of 0.6 is shown in the production account; the contributions by the employer are shown as payable by the employer in the generation of earned income account and receivable by the households in the allocation of ~~primary~~earned income account.

~~24.166~~24.178 In the allocation of ~~primary~~earned income account, investment income is also shown. The increase in pension entitlement coming from ~~past service, due to~~ the unwinding of the discount factor because retirement is one year nearer, is 4. This is shown as an imputed flow of investment income from the pension fund to households. At the same time, the pension fund actually earns 2.2 from investment income of the funds they manage. ~~At this point, therefore, there is a shortfall of 1.8 in the pension fund resources but it is not shown in the current accounts. The difference between the unwinding of the pension entitlements and the actual investment income received is to be recorded as (imputed) investment income on the claim between a pension fund and its sponsor. As a consequence, the entitlement coming from past service is matched by actual receivables of investment income and imputed investment income receivable from the pension manager.~~

~~24.167~~24.179 In the ~~secondary distribution of~~ income transfers other than social transfers in kind accounts, the payments from households to the pension fund are shown. This can be viewed in one of two ways. The sum of the contributions paid by households should be equal to the increase in entitlements coming from current service (15) plus that coming from income on past entitlements (4) or 19 in total. The amounts actually paid are 10 received as the employers’ actual contributions, 4.1 as the imputed contributions, 1.5 of the households own contributions, contribution supplements of 4 less the service charge of 0.6; again 19 in total. In the same account pensions of 16 are also shown as payable by the pension fund to households.

~~24.168~~24.180 In the use of income account, as well as the purchase of the service charge as part of household final consumption expenditure, the change in pension entitlement is shown as payable by the pension fund to households. In this example, the amount of household contributions of 19 is set against pension benefits of 16. There is thus an increase in pension entitlements of 3 owing to households.

~~24.169~~24.181 Households have saving of 17.5 of which 3 is the increase in their pension entitlements. This means that they have acquired other financial assets (or reduced liabilities) by 14.5. This figure is the difference between the benefits received (16) and households’ actual contributions of 1.5.

~~24.170~~24.182 For pension funds, saving is ~~-1.20.6~~ but this can be seen as the composite of the actual and imputed elements. In terms of actual flows, pension funds receive contributions of 10 from employers routed via households, 1.5 from households and pay out benefits of 16. In addition, they receive investment income of 2.2. Their disposable income is thus -2.3. When the change in pension entitlements of 3 is taken into account, saving is -5.3. In addition, employers make an imputed contribution of 4.1 and also pay an imputed investment income on the claim of the pension fund of 1.8. ~~This~~The former element is routed via households. Both elements together ~~but~~ adds ~~4.15.9~~ to the saving of the pension fund and reduces saving of the employer by the same amount.

~~24.171~~24.183 In the financial account of the pension fund, the figure of 4.1, which was the imputed contribution, as well as the figure of 1.8, which was the imputed investment income, are ~~is~~ shown as the claim of the pension fund on the employer. There is a claim by households on the pension fund of the change in pension entitlements of 3. In addition the pension fund either runs down financial assets or increases liabilities by 2.3, the figure corresponding to disposable income excluding the imputed contribution element from the employer.

### Transactions for ~~D~~efined contribution pension schemes

~~24.172~~24.184 Table ~~4724.7~~ shows the similar flows for a defined contribution scheme. The accounts are simpler, compared to the defined benefit case, because there are no imputed contributions. Further, the investment income payable by the pension fund to households reflects only investment income received by the pension fund and does not involve calculations about increases in entitlement from the operation of a formula.

~~24.173~~24.185 The investment of the entitlements of defined contribution pension schemes leads to holding gains (and

possibly losses). These come about through the management of the assets held by the fund but an amount exactly equal to the holding gains and losses should be attributed as an increase in the pension entitlement of the beneficiaries. The holding gains appear under entries for the relevant assets in the revaluation account for the pension fund with a matching entry for the increase in the liability of the pension fund towards households.

### *Other flows for ~~a~~ defined benefit pension schemes*

~~24.174~~24.186 At first sight it would seem that there are no entries to be made in the other changes in assets accounts for a defined benefit pension scheme since the two components recorded as the pension contributions and investment income are matched exactly to the increase in entitlements. However, because the nature of a defined benefit pension scheme is that the amounts due are determined by a formula, there are other factors that may intervene to change the level of entitlements. These factors include, for example, actuarial gains and losses, i.e., changes in entitlements resulting from experience adjustments (the effects of differences between the previous actuarial assumptions and what has actually occurred) and the effects of changes in actuarial assumptions, among which changes in the discount rate, changes in demographic assumptions about life length and other changes in the formula used to determine benefits. It may also include the impact of settlements that eliminate all further entitlements for part or the whole of entitlements, a price escalation clause, changes in the formula used to determine benefits and demographic assumptions about life length. The special case of the impact of promotions on entitlements is discussed separately below. These changes in entitlements are generally to be recorded as other changes in the volume of assets and liabilities, unless they are clearly driven by a price element (such as change in the estimates of entitlements due to changes in the expected levels of price indexation).

~~A pension fund invests the funds at its disposal. If they work on a fully funded basis, the investment income should be more than enough to cover any price escalation clause in the pension agreement. The excess may also be sufficient to cover some other adjustments to entitlements. However, a major source of revenue comes from holding gains on investments. These were assumed to be sufficient to cover most or all changes in entitlements. It has become clear that many schemes were underfunded in the expectation that holding gains would make up this shortfall also.~~

~~Given these adjustments are funded in large part by holding gains which appear in the revaluation account, it seems reasonable to record the contingencies that they are assumed to cover in the other changes in the volume of assets account except for the price escalation factor which should appear in the revaluation account.~~

### *The issue of promotions*

~~Many defined benefit pension schemes use a formula to set benefits that involves either the final salary or average salary as a key determinant. This implies that any promotion means that the total pension entitlements accrued to date are increased to take account of the new salary level. This is a significant benefit for the individual being promoted but what are the consequences for the employer's pension liabilities?~~

~~The accounting profession uses two actuarial terms that bear on this discussion. The accrued benefit obligation (ABO) records, as its name implies, only the benefits actually accrued to date. It represents the amount the employee could walk away with if he left the firm tomorrow and may be the basis of assessing a person's net worth in the case of a divorce settlement, for example. A projected benefit obligation (PBO) is a more prudent measure of what the eventual level of entitlement is likely to be. For an individual, the PBO makes assumptions about how many future promotions the person is likely to receive and calculates his final salary accordingly. Then, if he has in fact only worked 20 out of an expected 40 years, it halves the final salary and calculates pension entitlement for the individual as if this were his current salary. Where an individual's ABO increases in steps as he is promoted, the PBO increases steadily over time. For the individual, PBO is always higher than ABO until the moment of retirement when the ABO catches up with the PBO.~~

~~It would seem at first sight that the level of pension entitlements for a corporation should be the sum of all the pension entitlements of each of the employees and that therefore the sum of the PBO estimates would be considerably higher than that of the sum of the ABO estimates and would evolve more smoothly over time. However, what is true for the individual is not necessarily true for the cohort of employees. Suppose the employer has five classes of people for whose pensions he is responsible, four grades of employees and one set of retirees, and for simplicity there are the same number of each. Consider the situation where in a year the retirees die; the most senior set of employees retire, the next three sets of employees are all promoted and a new set of employees is recruited at the lowest level. Every current employee is better off after promotion but the overall liability of the employer has not changed. The effect of aggregating ABOs is to smooth the total entitlement and while it will still be lower than the aggregate PBOs, it will not necessarily be more volatile. Indeed it may be more stable.~~

~~While the profile of the ABO of an individual will show step changes when promotions occur, for a cohort of employees, the effect is much smoother. For a cohort of the same age remaining with the corporation for the whole of their working lives, the ABO estimates will be considerably lower than PBO estimates in the early years but the rate of increase of the ABOs will be faster than that of the PBOs so that at the point immediately before retirement, the two sets of estimates will be equal. Merging cohorts of employees with different periods of service with the corporation will bring the ABO estimates for all employees closer to the PBO ones also.~~

~~As long as the grade structure of the corporation stays the same, ABO and PBO will move roughly in step. If the firm expands and takes on many new employees at the lower grades, the PBO will increase noticeably faster than the ABOs because the PBOs make estimates of how long the new employees will stay and how far they will be promoted while the ABOs record simply the pension accrued in their first year. If the firm decides to downsize and reduces the number of their managerial staff, this will reduce the promotion prospects of the employees and a downward revision in PBO will be necessary. Because ABOs reflect simply the "locked-in" pension, this estimate is not affected.~~

~~The question arises, though, of how to record the impact of promotion on the employee if an ABO recording is used. Any version of treating the increase as a form of compensation of employees or investment income falls back into the assumption that the aggregate of entitlements is the sum of the individual entitlements but without looking at other individual impacts on the aggregates such as when someone leaves and loses pension entitlement because not enough time has been served or when someone dies before retirement age. A simpler and adequate solution is to treat the impact of promotions for the unit as a whole as a price change and record the change in the revaluation account.~~

~~If the PBO method of recording entitlements is chosen as the preferred valuation, an adjustment in the other changes in volume of assets account is needed only if the structure of the enterprise changes so the chances of promotion change. On the other hand, the regular estimates of the employer's contributions to social insurance schemes included in compensation of employees will be systematically higher than those made under an ABO regime because the increase in pension entitlement that determines the size of the contributions will be based on a notional salary calculated on a PBO basis rather than the actual one.~~

### 3. Transferring pension entitlements

~~24.175~~24.187 One characteristic of the changing environment of pensions is the increasing possibility of having "portable pensions". ~~Until recently it was often~~It used to be the case that a person leaving one employer had his pension frozen at that point and had to start a new pension with the new employer. It is becoming more common now for a person moving jobs to be able to convert the pension entitlement with the former employer to one with the new employer. When this happens, the pension entitlement of the household concerned is unaffected but there is a transaction between the two pension funds as the new one assumes the liability of the former. In addition there will be a counterpart transaction in some assets to match these liabilities. If the new employer is running a scheme that is actually unfunded, he may receive cash from the former employer. If this cash is then used by the

employer for purposes other than the pension fund, his liability to the fund increases and his use of the cash appears as net borrowing.

24.188 More generally, pension entitlements may be transferred between schemes. These transfers may be fully required, partially required, or non-required. In the case of a fully required transfer, the transfer of entitlements is accompanied by an equal transfer of funds, and the transfer of the entitlements as well as the transfer of the funds should be recorded as financial transactions. The transfer of funds may include the claim on the pension manager, if the pension manager remains responsible for the shortfall of accumulated assets. In the case of a partially required transfer which is accompanied with a change of the unit being responsible for the shortfall, the difference between the value of the pension entitlements and the value of the transferred funds should be recorded as a capital transfer between the unit taking over the responsibility for the entitlements (i.e., the new pension manager) and the unit who originally had the responsibility for the scheme (i.e., the original pension manager).

24.17624.189 Non-required transfers may happen. If for example government assumes the responsibility for pension provision for the employees of a non-government unit through an explicit transaction, in such a case, a pension liability should be recorded in the balance sheet of government. If the government does not receive any matching assets in return, the difference between the increase in the government's liability and the assets received is shown as a capital transfer to the non-government employer. There is further discussion of this type of arrangement in chapter 2230.

24.190 Another way in which pension entitlements may be transferred between funds is when one corporation takes over another. If the pension fund is a separate institutional unit, all that changes is control of the pension fund. If there is no separate institutional unit, assuming the takeover does not change the terms of the pension plan for existing participants, the corporation being taken over passes both the pension liabilities and the corresponding assets to the new owner.

24.191 Finally, sometimes a transfer of entitlements may involve a reduction in the value of pension entitlements. For example, in the case of an employer bankruptcy, the scheme taking over (transferring in) the pension entitlements of the bankrupt employer's scheme may only offer members a proportion of the value of the future benefits (not the full benefits). Such a reduction should be recorded as an other change in the volume of assets, and in the case the original debtor still exists, a subsequent capital transfer for the reduced value from the unit taking over the entitlements to the unit transferring out the entitlements. In case the original debtor does not exist anymore, the original entitlements should be written down in full, via an other change in volume of assets, followed by a capital transfer from the unit taking over the reduced entitlements to the beneficiaries, combined with a financial transaction in entitlements.

#### 4. A note on the tables

24.17724.192 For cross-reference with tables in other chapters, table 4724.9 shows the itemized components of transactions pertaining to social and other insurance in tables 4724.1 to 4724.8 inclusive.

**Table 4724.9: Detailed transactions concerning social insurance**

#### **K. The special case of government providing pensions via social securityA supplementary table for pension schemes**

24.17824.193 In recognition of the fact that social security is normally financed on a pay-as-you-go basis, entitlements accruing under social security (both pensions and other social benefits) are not normally shown in the SNA. If all countries had similar benefits provided under social security and under ~~private~~other social insurance pension schemes, international comparisons would be relatively straightforward. However, as pointed out at in section H~~the beginning of this part~~, this is far from being the case and national perceptions of exactly what is covered by social security vary considerably.

24.17924.194 There are two problems with simply suggesting that entitlements from social security should be shown in the SNA. The first is that reliable estimates of the entitlements may not be readily available whereas it is

increasingly the case that such estimates exist for ~~private~~other social insurance pension schemes. Secondly, there is an argument that such estimates are of limited usefulness where government has the possibility of changing the basis on which entitlements are determined in order to keep the entitlements within the bounds of what is budgetarily feasible. However, the consequence of simply accepting that entitlements for ~~private~~other social insurance pension schemes are shown and for social security are not is that some countries would include the greater part of pension entitlements in the accounts and some would show almost none.

~~24.180~~24.195 In recognition of this dilemma, some flexibility regarding the recording of pension entitlements of unfunded pension schemes sponsored by government for all employees (whether private sector employees or government's own employees) is provided. Given the different institutional arrangements in countries, only some of these pension entitlements may be recorded within the ~~main~~ sequence of economic accounts (~~here referred to as the "core accounts"~~). In addition, however, a further table is to be presented that provides information ~~disclosing the proportion of on~~ pension provision covered in the ~~core~~sequence of economic accounts as well as pension provision covered by ~~with some approximate estimates for~~ the remaining schemes. The aim of the supplementary table is to provide a full picture of countries' social insurance pension entitlements of resident and non-resident households, and related (constructive) liabilities of the pension providers. It is a requirement, though, that a set of criteria be provided to explain the distinction between those schemes carried forward to the ~~core~~sequence of economic accounts and those recorded only in the supplementary table.

~~24.196~~ The sort of criteria that might be considered are the following: Where a pension scheme provided by government or a public corporation in its role as an employer is clearly separated from social security pension schemes, the closer that the government employer pension scheme is to the prevailing pension arrangements provided by private employers, in the sense of being derived from an employer-employee relationship with similar terms and conditions of compensation, both current compensation and future compensation after retirement, social security scheme, the less more likely it is to appear in the core sequence of economic accounts. ~~Furthermore,~~ the less the benefits are tailored to the specific characteristics of the individual and the more they are applicable to the population at large, the less likely it is to appear in the ~~core~~sequence of economic accounts. ~~the greater~~ Also the ability of government to alter the benefit formula, would make it the less likely that the entitlements it is to would be recognised appear in the ~~core~~sequence of economic accounts. However, none of these criteria alone is necessarily decisive in determining whether the scheme is treated in the core accounts or not.

~~24.181~~24.197 By making this supplementary table and annotation a standard requirement for international reporting, analysts have the possibility of ensuring that cross country comparisons are not unduly clouded by the institutional variations from country to country. Further work on refining the criteria for the distinction between the pension schemes fully recorded in the core accounts and those where the entitlements are shown only in the supplementary table is to be part of the SNA research agenda.

~~24.182~~24.198 The supplementary table is shown in table ~~17~~24.10. As well as the possibility of including less robust estimates for countries with large social security sectors, the possibility will also exist of working back to a narrower coverage of private pensions for all countries being analysed.

**Table ~~17~~24.10: A supplementary table on social insurance pension schemes showing the extent of pension schemes included and excluded from the SNA sequence of accounts**

~~24.183~~24.199 As noted above, providing detail on defined contribution schemes is relatively straightforward since full accounts must be available and no actuarial estimation is involved. Most of these are in the corporations sectors (column A) but it is possible that some government employees may be covered by them (column D). All defined contribution pension schemes should be included in the ~~core~~sequence of economic accounts. Estimates for all defined benefit pension schemes outside social security should also be included (column B).

~~24.184~~24.200 Government schemes for their own employees where separate accounting information, distinct from social security, is shown in the ~~main~~ sequence of economic accounts appear in columns E and F. Column E shows schemes ~~administered~~managed by an insurance corporation, or a separate institutional unit, and column F those ~~administered~~managed by government itself. Any government schemes for their own employees distinct from social security ~~that for which the pension entitlements~~ do not appear in the ~~main~~ sequence of economic accounts, are shown in column G. The sum of columns E, F and G therefore show the total responsibility of government

for pension provision for their own employees. (Column F shows that part of all defined benefit schemes of government that are retained within the government accounts as distinct from being moved into separate units or ~~administered~~managed for government by another institutional unit. Column H relates to social security schemes. Column C shows the total of all non-government schemes and column I the total of all schemes including social security.

~~24.185~~24.201 For the most part, the beneficiaries of pension schemes are likely to be resident households. In some countries, though, the number of non-resident households receiving pension benefits may be significant. In this case, column J should be added indicating the amount of the total that concerns non-resident households.

~~24.186~~24.202 Some of the entries in the rows of columns G and H, specifically the actual contributions made by both employers and employees and benefits received, appear in the ~~sequence~~sequence of economic accounts, even though the entitlements and change in entitlements do not. Other entries in the columns for G and H are only shown ~~only~~ in the supplementary table. These are shaded in the table indicating that these entries do not appear in the sequence of economic accounts, and explained below.

~~24.187~~24.203 The imputed contribution by employers for those government schemes for which entitlements appear in column G but not in the ~~sequence~~sequence of economic accounts requires special consideration. In the ~~sequence~~sequence of economic accounts, this item is calculated, by convention, as equal to the difference between current benefits payable and actual contributions payable (by both employees and employers). In the supplementary table, this is replaced by the amount needed to ensure the total contributions, actual and imputed, by both employers and employees, covers both the increase in pension entitlements from current service and the costs of operating the scheme. Therefore, the imputed employer contributions row is measured as a balancing item: it captures any changes in entitlements over the year not included in other rows of the table.

~~24.188~~24.204 An item calculated on the same basis in respect of social security (column H) is shown in row 3 as “other (actuarial) accumulation of pension entitlements in social security funds”. The distinction from employers’ imputed social contributions is deliberate and is intended to emphasize the probable fragility of these estimates.

~~24.205~~ Items for household social contribution supplements and the other changes in entitlements are shown on the same bases as for ~~private~~defined benefit schemes as recorded in the sequence of economic accounts; see paragraphs 24.157 to 24.169.

~~24.189~~24.206 Changes in pension entitlements due to transfers of entitlements between schemes are recorded as transactions in the supplementary table (as in the sequence of economic accounts).

~~24.190~~24.207 Changes in pension entitlements are recorded as transactions, more specifically capital transfers (in relevant cases to be routed via the pension fund involved), as follows~~in the following cases:~~

- a. If the pension scheme is included in the ~~sequence~~sequence of economic accounts, and the employer manager agrees a change in the terms of pension entitlements via negotiation with the affected employees, this change should be recorded as a transaction in the ~~sequence~~sequence of economic accounts.
- b. If the pension scheme is not recorded in the ~~sequence~~sequence of economic accounts, and the employer manager agrees a change in the terms of pension entitlements via negotiation with the affected employees, this change should be recorded as a transaction in the supplementary table.
- c. In the case of social security, if changes in entitlements are agreed in parliament, this is also recorded as if it is negotiated in the supplementary table.

~~24.191~~24.208 Changes in pension entitlements that are imposed without negotiation are recorded as other changes in the volume of assets

~~24.209~~ The difference in the type of recording is one of principle but it is recognized that the distinction between what is negotiated and what is imposed without negotiation will be difficult to determine in practice with different situations prevailing in different countries.

~~24.192~~24.210 In addition to having a supplementary table on social insurance pension schemes, it could be considered to compile a supplementary table on household retirement resources. Such a table would focus on resident households. Moreover, it would not only include entitlements related to social insurance, both the ones recognised and the ones not recognised in the sequence of economic accounts, but could also include other types of retirement products, such as saving accounts with or without special fiscal arrangements. It could also be extended with the

value of dwellings or other accumulated wealth items, which are often used to compensate for the drop in income after retirement. The development of such a table has been put on the research agenda of the 2025 SNA, as the table would need further elaboration, especially in relation to arriving at a table which can provide adequate international comparisons.

## Chapter 25: Selected issues in financial instruments

### A. Introduction

- 25.1 This chapter provides additional details on specific financial instruments, as a supplement to chapters 12, 13 and 14. It also touches on issues related to the recording of flows associated with financial assets and liabilities in the broader sequence of economic accounts.
- 25.2 The chapter first covers guarantees, discussing both the concept and treatment as well as discussing some common types of guarantees. It then provides an exposition on financial derivatives, focusing on the definitions, conventions, classification, as well as valuation of these instruments, followed by a section on employee stock options. Lastly, this chapter provides some guidance on the recording of flows in financial instruments. This includes transactions as well as other changes in assets and liabilities.

### B. The treatment of standardized guarantees

#### 1. Overview of guarantees

- 25.3 A guarantee is an arrangement whereby one party, the guarantor, undertakes to protect asset holders and/or debtors in the case of events (sometimes unforeseen) such as one party's financial impairment. Often a fee is payable for the provision of a guarantee, though the form of this varies by type.
- 25.4 As a simple example, a loan guarantee is normally an arrangement whereby the guarantor undertakes to a lender that if a borrower defaults, the guarantor will make good the loss the lender would otherwise suffer. In other words, the guarantor will compensate the creditor for the loss of the principal amount and any accrued interest with respect to the loan balance in default. Sometimes the guarantor will acquire some rights over the defaulting borrower. Other types of guarantees with similar characteristics may be offered in respect of other financial instruments, including deposits. This section refers to guarantees on different financial instruments.
- 25.5 Guarantees have a significant impact on the behaviour of economic agents, both by influencing their decisions on production, income, investment or saving and by modifying the lending and borrowing conditions on financial markets. Some borrowers and depositors might have no access to loans or be willingunwilling to make deposits in the absence of guarantees. Guarantees are particularly significant for the general government sector and for the public sector as government activities are often linked to the issuance or activation of guarantees.

#### —Classes of guarantees

- 25.6 Three classes of guarantees are recognized. No special treatment is proposed for guarantees in the form of manufacturers' warranties or other form of guarantee. (The cost of replacing defective merchandise is an intermediate cost of the manufacturer.)
- 25.7 The first class of guarantees is composed of those guarantees provided by means of a financial derivative, such as a credit default swap. These derivatives are actively traded on financial markets. The derivative is based on the risk of default of a reference instrument or item, but it does not share the characteristics of standardized guarantees. This sort of financial derivative is discussed later in this chapter.
- 25.8 The second class of guarantees are one-off guarantees. These consist of those where the loan or the security, or the events giving rise to the guarantee, are so particular that it is not possible for the degree of risk associated with the debt to be calculated with any degree of accuracy. In most cases, the granting of a one-off guarantee is considered a contingency and is not recorded as a financial asset/liability. If a fee is charged, this is recorded as a payment for a service at the time of payment. If a call is made under a guarantee, a capital transfer (for the difference between the call amount and the fair value of the recoverable retained) is recorded

from the guarantor to the guarantee holder at the time of default ~~or, in cases where the guarantor obtains an effective claim on the guarantee holder, a financial transaction (including increases in equity participation) is recorded.~~

- 25.9 A specific type of one-off guarantee is the implicit guarantee that can occur in times of financial instability (e.g., the financial crisis, the pandemic), where governments may decide that one or more financial institutions are “too large to fail”. These are a type of one-off guarantees granted by governments to corporations in certain well defined financially distressed situations and have a very high likelihood of being called. The ~~implicit~~ guarantees are called when the financial distress is recognized and are then treated similarly to other one-off guarantees. One-off guarantees are discussed in more detail in Chapter 30 on the general government and public sector.
- 25.10 The third class of guarantees, standardized guarantees, is the focus of this section. These are comprised of the sorts of guarantees that are usually issued in large numbers, ~~usually~~ for fairly small amounts, and along identical lines. ~~There~~ As with all guarantees there are three parties involved in these arrangements, the debtor, the creditor, and the guarantor. Either the debtor or creditor may contract with the guarantor to repay the creditor if the debtor defaults. Here, although it is not possible to establish the likelihood of any one debtor defaulting, it is standard practice to estimate how many out of a batch of similar debts will default. In this sense, the general probability of default can be established. Such guarantees can be generically defined as arrangements whereby the guarantor has an obligation to pay a third-party beneficiary when another institutional unit fails to perform certain contractual obligations.
- 25.11 If the guarantor is working on purely commercial lines, they will expect all the fees paid, plus the investment income earned on the fees and any reserves, to cover the expected defaults along with the costs and leave a profit. This is the same approach as for non-life insurance and a similar treatment is adopted for these guarantees, described as “standardized guarantees”. This involves including transactions and balance sheet items in the same way as those for non-life insurance, including the generation of output and payments of a fee supplement and a service fee by those taking out the guarantees.
- 25.12 Standardized guarantees are to be distinguished from one-off guarantees based on two criteria: ~~First: (i)~~ they are characterized by often repeated transactions with similar features and pooling of risks; ~~and second: (ii)~~ guarantors can estimate the average loss based on available statistics by using a probability-weighted concept. One-off guarantees are, on the contrary, individual, and guarantors are not able to make a reliable estimate.
- 25.13 The treatment of standardized guarantees follows.

## 2. Standardized guarantee schemes

### Basic concepts

- 25.14 Standardized guarantees may be provided by a financial institution, including but not confined to insurance corporations. They may also be provided by government units. It is unlikely that non-financial corporations may provide these sorts of guarantees. It is also unlikely that they would be initially provided by any unit to a non-resident unit, although with student loans the borrower may relocate abroad upon completion of their studies. In certain instances, transnational organizations may be involved in standardized guarantees. As indicated above, standardized guarantee schemes have much in common with non-life insurance. In the general case, similar recording is recommended as described below.
- 25.15 When a unit offers standardized guarantees, it generally accepts fees (for exceptions, see paragraphs 25.30-25.33) and incurs liabilities to meet the call on the guarantee. The value of the liabilities in the accounts of the guarantor is conceptually equivalent to the present value of the expected calls under existing guarantees, net of any recoveries the guarantor expects to receive. The liability is entitled provisions for calls under standardized guarantees, and it consists of prepayments of ~~net fees~~ less service charges and provisions to meet outstanding calls under standardized guarantees.
- 25.16 Standardized guarantees can be limited or unlimited. If unlimited, it ensures that the party benefiting from the guarantees receives full compensation in the event of a default. If the guarantee is limited, the guarantor has only insured for a loss up to a certain amount.

- 25.17 The nature of the standardized guarantee scheme is that there are many guarantees of the same type, though not all for exactly the same time period nor all starting and finishing on the same dates. A guarantee may cover a multiyear period, with a fee payable annually or upfront. In principle, the fee should represent charges earned in each year the guarantee holds with the liability decreasing as the period gets shorter. As a result, the same sort of recording should be followed here as for annuities, with the fee paid earned as the future liability decreases. This is the preferred approach but, in practice, some units operating guarantees may have data only on a cash basis. While the ideal approach in such cases would be to recognize the guarantee fee over multiple periods, when this cannot be done then a cash accounting approach will have to be accepted. ~~This is~~ While this would be inaccurate for an individual guarantee ~~but, it is~~ acceptable ~~when for standardized guarantees where there are~~ a steady flow of many guarantees ~~in such standardized guarantee arrangements granted~~. Unless there is reason to suppose that there is a major change in the nature of the guarantee holders over time, using cash-based data should not introduce significant error.
- 25.18 The guarantors would record a liability for “provisions for calls under standardized guarantees schemes” on its balance sheet account (see paragraph 25.15), and this amount would evolve over time. The corresponding asset would be reflected on the books of the guarantee holder: (creditor/lender). Conceptually, it could be argued (at least, for marketable instruments) that the total value of the instruments under guarantee on the balance sheet of the holder should be reduced by the extent of provisions for standardized guarantees which are estimates of the amount of borrowers’ debt that will be in default. However, this approach undermines the interpretation of stated balance sheet values, as the debtor remains contractually obliged to pay the full amount unless the debt is either forgiven or written off. This is consistent with the treatment of provisions for loan default which are not deducted from loan balances. In any case, this amount in provisions is not likely generally to be significant compared with the total value of the instrument holdings concerned.
- 25.19 Altogether, six sets of transactions need to be recorded in respect of standardized guarantee schemes: two relating to the measurement of the production and consumption of the guarantee service, three relating to redistribution and one in the financial account. The value of the output of the activity, the investment income to be attributed to the guarantee holder (whether creditor or debtor) and the value of the service ~~charge~~ charges are calculated in the manner described above for non-life insurance with the concepts of fees replacing premiums and calls under a standardized guarantee scheme replacing claims.
- 25.20 The production and consumption transactions are as follows: The output is recorded in the production account of the sector or subsector to which the guarantor belongs. The service may be paid for by either the borrower or the lender of the debt being guaranteed. When non-financial corporations, financial corporations, general government or non-profit institutions pay fees to obtain this sort of guarantee, the service part of the fees constitute intermediate consumption, recorded in their production account. The corresponding expenses for such guarantees payable by households are part of final consumption expenditure, recorded in the use of income accounts.
- 25.21 The redistributive transactions cover investment income attributed to guarantee holders in respect of standardized guarantee schemes, ~~net~~ fees less service charges, and calls under standardized guarantee schemes.
- Investment income associated with the provision for calls under a standardized guarantee scheme (that is, on the technical reserves of the scheme) is recorded as payable by the guarantor and as receivable by the unit paying the fee: (see paragraph 8.148). Both payables and receivables are recorded in the allocation of primary earned income account.
  - ~~Net fees~~ Fees less service charges are calculated as fees receivable plus fee supplements equal to the investment income attributed to the unit paying the fee for the guarantee less the value of the services consumed. They exclude administrative and other costs. These ~~net~~ fees are payable by all sectors of the economy and receivable by the sector of the guarantor.
  - Calls under standardized guarantee schemes are payable by the guarantor and receivable by the lender of the debt under guarantee, regardless of whether the fee was paid by the lender or the borrower. Both ~~net~~ fees less service charges and calls are recorded in the secondary distribution of transfer income account. This treatment is analogous to non-life insurance.
- 25.22 In the financial account of the relevant parties, the transactions entries for the instrument provisions for calls under standardized guarantee schemes show the difference between receipt/payment of fees for new

guarantees and calls made under existing guarantees. When a standardized guarantee is activated during its lifetime, the liability of the debtor is written off (or written down) by the creditor in the other changes in assets and liabilities account.

### **Some common types of standardized guarantees**

- 25.23 As noted above, standardized guarantees can be offered by private sector entities or public sector entities. For the former, these are most often insurance companies, although it may also occur in the case of related corporations such as a parent/affiliate or holding company in the same economy (usually for providing guarantees on instruments like trade receivables). For the latter, guarantors are either government bodies themselves or public corporations. Each of these types of units may offer various standardized guarantees. What types of such guarantees are offered can differ across countries, based on demand, financial stability concerns, or more general public policy.
- 25.24 Export credit insurance is a standardized guarantee that functions to ensure that exporters receive payment for goods shipped abroad in the event of foreign customer default, thus reducing business risks. This helps promote domestic economy exports, and it may also lead to more competitive prices for exporters. Such an agency is typically a public sector unit (export development agency).
- 25.25 There are various types of potential loan guarantees, applicable on different loan instruments and offered by public or private sector guarantors. Please refer to the UN ECB Handbook Financial Production, Flows and Stocks in the System of National Accounts for a detailed example of loan guarantees.
- 25.26 Guarantees on loans can protect the creditor and support the debtor, but these contracts can be structured in different ways to meet policy or income objectives. This can include insurance on consumer or business installment loans, primary mortgages and on home equity lines of credit, the latter being a second mortgage. This type of insurance can be optional or mandatory. Two examples may provide further clarification. First, in some economies, there may be mortgage insurance arrangements to promote home ownership with public sector units involved (and there may be an approved list of lenders); or, such insurance arrangements may competitively emerge in the mortgage market. Essentially, the guarantor assumes the responsibility for the debt if the owner defaults, but the guarantor may also have a residual claim on the property in case of default. Such arrangements may involve situations where a prospective homeowner has a smaller down payment than normally required by the lender. The lender typically pays a premium to the guarantor (based on mortgage size and/or the down payment), while passing the cost onto the borrower.
- 25.27 Second, there can also be standardized guarantees associated with homeowners drawing on the value of their home equity for various purposes. These include home equity lines of credit where minimum monthly payments of principal and interest are required. In these instances, it is more likely that the guarantor is a private insurance corporation, and the fees are paid by the borrower as part of the regular payments and are tied to the current outstanding balance of debt.
- 25.28 In some countries, with the objective of promoting higher education, student loans from private lenders are supported by standardized guarantees. In these instances, usually a government unit assumes the role of guarantor.
- 25.29 In some economies, debt securities can also be subject to standardized guarantees, where the timely principal and interest payments are guaranteed by a third party in the case of issuer default. The guarantor can be a government unit in the case of guaranteed debt securities of entities such as with public corporations, municipal governments, universities, or hospitals. Although less common, guarantors can also be private insurance companies, depository corporations or affiliated companies. These types of arrangements make for safer investments and can help to secure favourable terms for issuers.
- 25.30 Deposit insurance acts to ensure trust in the banking system, thus helping to promote a sound financial system. This is another type of standardized guarantee that is offered in many economies and/or regions. The provision of deposit insurance has expanded since the financial crisis that began in 2007. Such standardized guarantees are usually offered by a public corporation or agency, sometimes associated with a central bank, but can also be offered by transnational institutions. Deposit insurance offers limited (up to a certain deposit amount or restricted to certain types of depository instruments) or unlimited protection to depositors in the

case of a failure of a deposit-taking institution. In this case, the member depository corporation is typically responsible for the annual premium on insured deposits payable to the guarantor ~~(in in some economies, the fee may be deemed to be a tax).~~ Member institutions may be classified by risk (e.g., liquidity) by the guarantor for premium establishment purposes, as part of assessing the statistical likelihood of calls. In this sense, it is somewhat different from other types of standardized guarantees. Deposit insurance, however, is not ~~always in the form of a standardized guarantee.~~ necessarily in the form of a standardized guarantee. In some economies, the annual premium on insured deposits is deemed to be a tax, where payments are not put aside. A standardized guarantee implies the existence of a fund functioning on insurance rules with a full set of accounts (see paragraph 8.84).

### **Standardized guarantees provided by government or public corporations**

- 25.31 Governments often offer guarantees for specific policy purposes, and their activity in certain areas can be significant. Student loan guarantees are one example. The guarantees may be issued by a government unit that can be treated as a separate institutional unit. When this is so, the normal rules for the allocation of government units to either publicly controlled corporations or as part of general government apply.
- 25.32 If a guarantee unit charges fees that are economically significant (in this case this may be equivalent to saying that most of the calls plus the administrative costs are covered by the fees charged), then this is a market activity. It should be treated as a private or public financial corporation, depending on ownership, and transactions should be recorded as described above. If the fees cover most but not all the costs, the recording is still as above: with the guarantor being a public corporation. The loss made by the agency offering the guarantees (particularly, a public corporation) may be covered by the government, on a regular or intermittent basis, but this is not passed on to those seeking the guarantees as a subsidy. Regular payments are recorded as a subsidy to the agency and intermittent payments, covering cumulated losses, are recorded as capital transfers only when such payments are made.
- 25.33 In general, when a government unit provides standardized guarantees without fees or at such low rates that the fees are significantly less than the calls and administrative costs, the unit should be treated as a non-market producer within general government. If government recognizes the probability of having to finance some of the calls under the guarantee scheme to the extent of including a provision in its accounts, a capital transfer of this size from government to the units concerned and a liability of this amount (under provisions for calls under standardized guarantees) should be recorded.
- 25.34 In the case of a government or public corporation unit providing standardized guarantees, this may be the specialized unit's main source of business. As a result, the accounting statements of this unit can provide a useful source of information to link to the financial statements of the guarantee holder counterparty.

## **C. Financial derivatives**

### **1. Basic concepts and terminology**

- 25.35 Financial derivatives are, in part, a response to both risks and uncertainties in the economic and financial environment and are used for hedging as well as investment/speculation purposes. They constitute a ~~category of~~ category of financial instrument with the distinguishing feature that they involve contracts that are determined in relation to the future values of specified other financial or physical variables, under definitions that are precisely stated and agreed between the parties to the contract. They enable the economic risks of future outcomes in the reference markets or phenomena to be transferred from one party to another in precise, standardized ways that can be highly flexibly implemented, reversed or otherwise varied. Financial derivatives enable parties to transfer large amounts of economic risk at little or no up-front cost. This has consequences that may be regarded sometimes as benign, such as when a party can use a financial derivative product to hedge against a risk that it does not want; or sometimes as potentially more precarious, such as when a party can readily establish a considerable speculative position in a dimension of risk.
- 25.36 More specifically (following the definition in Chapter 12), financial derivatives are financial instruments that are linked to another specific financial instrument or indicator or commodity, through which specific financial

risks (foreign exchange or interest rate risk, equity or commodity price risk, credit risk, etc.) can be managed - that is, traded ~~in~~ in their own right on financial markets. More specifically, the risk embodied in a financial derivative contract can be managed by trading the contract itself in the case of exchange-traded contracts; or the risk can be offset in the case of over-the-counter contracts.

- 25.37 Financial derivatives constitute contractual arrangements whose values change in response to price movements in a primary asset or indicator – referred to as the reference price. In other words, the value of a derivative contract is derived from the primary item. This underlying item can include currencies or exchange rates, agricultural commodities, crypto assets stocks or stock market indices, precious metals, debt securities, interest rates, and a basket of prices or a spread between prices, and ~~another~~ other financial ~~derivatives~~ derivatives. As such, an observable current value (market price or index) for the underlying item is generally required to construct a derivative contract and to calculate the value of the derivative over the term of the contract. However, financial derivatives are separate assets from the primary item.
- 25.38 Two key characteristics of derivative contracts are that usually no up-front payment or a small up-front payment (e.g., premiums on options) is advanced, and no investment income accrues. Further, no principal amount is advanced, except for foreign exchange swaps where notional amounts may be exchanged at the beginning and end of the agreement. While some contracts are settled by delivery of the underlying items (e.g., foreign currencies, commodities), in many or most cases contracts are settled by payments of net amounts in cash. A distinct advantage of derivative contracts is that they allow for the replication of positions in various items at a much lower cost, due to their leveraged nature. This is because any cash outlay for initiating these contracts is considerably less than taking a similar position in the underlying item. While some contracts (e.g., options) charge a premium at contract inception, most types of derivative contracts have no initial cost.
- 25.39 Financial derivatives are used for several purposes, and the parties to a derivative transaction may have different motives, including hedging, speculation, arbitrage, and general risk management. One party may be hedging, while the other may be dealing in derivative instruments or acquiring the derivative as an investment. Even if both parties are hedging, they may be hedging transactions or risks that involve different financial assets or even transactions in different accounts. Therefore, if derivative transactions were treated as integral parts of other transactions, such treatment would lead to asymmetries of measurement in different parts of the accounts or to asymmetries/imbbalances of measurement between institutional sectors.
- 25.40 Whatever the motive, there are some common considerations for the investors. For example, hedging involves taking positions in items negatively correlated with a given risk. For this, the investor determines the size of the derivative position to be taken to reduce the risk exposure by a desired amount, considers that the reference price can fluctuate over the course of the contract, and accounts for any associated opportunity costs. On the other hand, speculation involves taking a position to make gains from anticipated, but uncertain, price movements. And, in this case, similar expectations and factors are accounted for on the part of both investors, though they may have different expectations about the future value of the underlying item.
- 25.41 There are two main classes of derivative instruments: ~~Forwards and options~~ Forward-type contracts and option-type contracts. That said, there are many types of sub-instruments (including hybrid derivatives) as well as different ways by which to classify derivative instruments. Certain types of financial derivatives are exchange traded (i.e., bought and sold on exchanges), while others are not. For example, futures contracts are exchange traded forwards, while other forward contracts are traded over the counter. Notably, the over-the-counter market can offer more customized contracts to investors.
- 25.42 Forward-type contracts can be contrasted with ~~options~~ option-type contracts in that:
- at inception, there is usually no up-front payment for a forward-type contract and, when initiated, the derivative contract begins with zero value, whereas there is usually a premium paid for an option representing a non-zero market value for the contract;
  - during the life of the contract, for a forward-type contract, either party can be creditor or debtor, and it may change, whereas for an option ~~(except for credit default swaps)~~ -type contract, the buyer is always the creditor, and the writer is always the debtor; except for a credit default swap (as either party to a credit default swap can be a creditor or debtor);
  - at maturity, redemption is unconditional for a forward-type contract, whereas for an option-type

contract it is determined by the buyer of the option.

- 25.43 The most highly standardized forms of financial derivatives are those products that are transacted on organized futures and options exchanges according to numerous contractual conventions, such as contract size, exercise dates and specified reference products. Such standardization promotes the liquidity of financial derivative positions. Exchange-traded contracts are fixed in terms of denomination and maturity dates, and they have a market valuation. The exchange makes the contracts highly liquid.
- 25.44 Outside of organized exchanges, more bespoke over-the-counter products, allow for greater flexibility and will be more suitable to end-users such as non-financial corporations. But even for these derivatives the use of master legal agreements and recognized market conventions enables there to be a substantial degree of standardization, promoting liquidity while minimizing unintended risks. Over-the-counter markets exist when there is no central trading facility, such as a stock exchange, and contracts are arranged through an inter-dealer market (over the counter market). In many countries, banks and investment dealers negotiate contracts, acting on their own behalf as “market makers” or as representatives of clients. Over-the-counter contracts can be more customized to meet the needs of the investors than exchange-traded contracts, however they are less liquid than exchange-traded contracts and may or may not be cleared and subject to margins.
- 25.45 An essential characteristic of financial derivative contracts is that the risk embodied in a derivative can be “traded”. This occurs either by trading the contract itself on an exchange (~~for~~ futures or options); where “buying” and “selling” the contract results in two countervailing positions (often referred to as “unwinding”); or, by creating a new contract that embodies risk characteristics that match, in a countervailing manner, those of the existing contract. The latter is generally termed “offsetability” and is used in over-the-counter markets. Offsetability means that it is often possible to eliminate the risk associated with a derivative contract by creating a new “reverse” contract having characteristics that countervail the risk underlying the first derivative. This is the functional equivalent of selling the first contract, in terms of eliminating the underlying financial risk. This practice is particularly common in forward markets, in cases where there are no formal exchanges through which to trade derivatives.

### **Exclusions from financial derivatives**

- 25.46 For clarity, it is worth noting items or financial arrangements that are not financial derivatives, but that are sometimes confused with derivatives. Insurance contracts and standardized guarantees (Section B) are not derivatives, as they manage risk by pooling. Contingent assets and liabilities, such as such as one-off guarantees and letters of credit, are neither assets according to the definition of the SNA, nor derivatives. Although repurchase agreements or reverse repurchase agreements (see paragraphs 12.~~xx~~80-12.~~xx~~83) involve a future commitment, they are not derivatives. The same can be said of business timing delays, that may entail exposure to price movements. A fixed-price contract for goods and services does not constitute a derivative, unless that contract is standardized, so that the market risk can be traded in financial markets in its own right. Gold swaps and central bank swap arrangements (see ~~paragraphs~~paragraph 12.~~xx~~12-12.~~xx~~84) are also not financial derivatives.
- 25.47 Instruments with “embedded derivatives” are also excluded. An embedded (or non-detachable) derivative arises when a derivative feature is inserted in a standard financial instrument and is inseparable from the instrument. Examples include bonds that are convertible into shares and securities with options for repayments in different currencies from the currency of issuance.
- 25.48 Subscription rights are classified as equity rather than financial derivatives, since the sum of the value of the shares after the subscription issuance and that of the subscription rights represent the total value of the corporation that issued the subscription rights.

## **2. Overview of types of financial derivatives**

### **Forwards**

#### **Forward-type contracts**

25.4825.49 Chapter 12 defines a forward contract as an unconditional financial contract that represents an obligation for settlement on a specified date. Futures and many other forward contracts are typically, but not always, settled by the payment of cash or the provision of some other financial instrument rather than the delivery of the underlying item. They are valued and traded separately from the underlying item. At the inception of a forward-type contract, risk exposures of equal market value are exchanged, so a contract typically has zero market value. As the price of the underlying item changes, the contract's market value ~~of the contract~~ will also change (although it may be restored to zero by periodic settlement ~~of~~ over the life of the forward). This means that the forward contract may switch between asset and liability positions, unlike standard option contracts.

25.4925.50 **Futures** are exchange traded forwards where two parties agree to exchange a specified quantity of an underlying item, whether financial or non-financial (e.g., energy, grain, livestock, currencies, stock indices, securities) at a particular price and for a period of time or subsequent date. These are standardized contracts, and the details are specified in contracts common to all participants and on an organized futures exchange. For example, bond futures represent an obligation to the holder to purchase or sell a bond (typically government debt securities) on a specified date at a predetermined price and can be used for both hedging and speculating purposes. The exchange facilitates trading by determining the standardized terms and conditions of the contracts, acting as the counterparty to all trades, and requiring margin to be deposited to mitigate risk. It is quite common that investors do not wish to obtain the item upon which the future is based, so they do not hold the contracts to maturity. This has led to robust secondary markets for futures. The clearinghouse function of the exchange makes it easy to unwind futures' positions prior to the settlement date. Unwinding is engaging in a second contract that takes a directly opposite position to the first.

25.51 There are also various over the counter **forwards** (e.g., foreign exchange contracts, forward rate agreements, swaps), but all involve exchanging assets, income flows, or commodities at a specified price (the "strike" price) on a specified future date. A swap contract involves counterparties exchanging, in accordance with prearranged terms, financial instruments or cash flows based on the reference rates of the underlying items. Over the counter forward contracts can be customized to meet investors' needs. They may not always be marked to market each day, and some do not require margins. These types of contracts normally cannot be traded but they can be offset. For foreign currency financial derivative contracts that could involve the exchange of principal (e.g., foreign exchange swaps, currency swaps, and foreign exchange forwards), the amount of foreign currency to be delivered at maturity is not recorded on balance sheets.

25.5025.52 Some examples of forward contracts are listed below.

- a. A **forward foreign exchange** contract (also referred to as a currency forward) involves two ~~counterparties~~parties who agree to transact in foreign currencies at an agreed exchange rate in a specified amount at some agreed future date. Take, for example, an importer of intermediate goods, who has signed a contract to purchase those goods in one year from now. If the agreement specifies payment for the goods upon delivery, the importer will pay for the goods in relevant foreign exchange on the future settlement date. This involves a risk from fluctuations in exchange rates. If the domestic currency depreciates in the meantime, the import costs will be higher. The importer can hedge this risk by entering into a forward foreign exchange contract to buy the required foreign currency at a specified price (perhaps at the known current exchange rate which may be acceptable from a cost perspective) when his payment is due. The counterparty to this derivative contract might be an investor who is speculating on an opposite movement in the exchange rate. Another example of a foreign exchange contract would be a debtor with foreign currency debt and periodic payments of interest and principal seeking to minimize exchange rate risks. In these types of contracts, either party can record unrealized gains and/or losses related to exchange rate fluctuations over the duration of the contract.
- b. ~~A foreign exchange swap, sometimes referred to as a currency swap,~~ involves a spot sale/purchase of currencies and a simultaneous forward purchase/sale of the same currencies. In effect there are two separate transactions, the first at the spot rate and the second at the forward price. There can also be periodic interest-like payments on the principal currency amounts (see paragraph 25.74), and sometimes principal payments. In this instance, the strike price could be set to the current exchange rate with similar results to the foreign exchange contract above.
- c. A **cross-currency interest rate swap**, sometimes also known as a cross-currency swap, involves an

exchange of cash flows related to interest payments and an exchange of principal amounts at an agreed exchange rate at the end of the contract. More simply, interest (at either fixed or flexible rates) and principal in one currency are exchanged for interest and principal payments in another currency. The locked in exchange rate means that the contract can experience holding gains/losses over its duration.

- d. An **interest rate swap** contract involves an exchange of cash flows related to interest payments or receipts in one currency, over a period of time, on a notional amount of principal (which is never exchanged). Settlements are often made through net cash payments from one counterparty to the other. One use of such a contract is the virtual conversion of fixed rate debt into floating rate debt. The ~~only event outcome~~ is the re-channeling of interest flows on the debt that the parties have previously negotiated. The creditors would be unaffected by this contract, and each party remains responsible for servicing its own debt. The main purpose is the opportunity to alter the cash flows associated with existing assets or liabilities. Other uses of interest rate swaps are to reduce the cost of financing by exploiting a comparative advantage in borrowing and or credit conditions, or for speculative purposes.
- e. A **forward rate agreement** is an arrangement in which two parties, to protect themselves against interest rate changes; ~~or for other purposes (e.g., speculation, arbitrage)~~, agree on an interest rate to be paid at a specified settlement date based on a notional amount of principal that is never exchanged. Forward rate agreements are settled by net cash payments. The only payment that takes place is related to the difference between the agreed forward rate and the prevailing market rate at the time of settlement. ~~The buyer of~~ One party to the forward rate agreement receives payment from ~~the seller~~ other party if the prevailing rate exceeds the agreed rate; ~~the seller receives payment or~~ if the prevailing rate is lower than the agreed rate.
- f. An **equity swap** is an exchange of future cash flows between two parties, where for one side the payments are based on a stock price or index and for the other side payments can be based on a fixed or floating rate or another stock price or index.

## Options

### Off-market swaps

25.53 An off-market swap has a debt component associated with it. The economic nature of this arrangement is a combination of a loan (the non-zero value provided to/from the counterparty at inception) and a financial derivative as an on-market swap. The off-market swap has a non-zero value at inception as reference rates are priced differently from market values (i.e., off the market), and produces two positions to be recorded: the loan and the financial derivative. Future streams of flows relating to these positions are also split between those relating to the loan component and those relating to the financial derivative component. Examples of swaps contracts that may involve off-market reference rates include interest rate and currency swaps.

### Option-type contracts

25.51 25.54 Chapter 12 defines **options** as contracts that give the purchaser of the option the right, but not the obligation, to buy (a “call” option) or to sell (a “put” option) a particular financial instrument ~~or~~ for commodity at a pre-determined price (the strike price) within a given time span for American option ~~or on a given date for a European option type~~ or on a given date for a European option type. The “premium leg” in standard put and call options is a fixed payment (premium) from the buyer to the seller at inception. When the option’s strike price is equal to the current market value of the underlying asset, it is considered “at the money”, and when it is not, it is considered either “in the money” or “out of the money”. Many options contracts, if exercised, are settled by a cash payment rather than by delivery of the underlying assets or commodities to which the contract relates. This single payment at maturity is called the “contingent leg” of the options-type contract, and its value depends on the price of the underlying item.

25.52 25.55 Options are sold or “written” on many types of underlying bases such as equities, interest rates, foreign currencies, debt securities, commodities, futures contracts, and specified indices. The buyer of the

option pays a premium (the option price) to the seller for the latter's commitment to sell or purchase the specified amount of the underlying instrument or commodity on demand of the buyer. However, option contracts frequently expire without having any value; options are exercised only if settling a contract is advantageous for the option holder.

~~25.53~~25.56 Options are largely exchange-traded in nature. This means that they are listed on an organized exchange, that they can be traded, and that they are subject to the typical conventions of exchange traded derivatives. This means that they are standardized contracts, and that the central clearinghouse necessitates the use of margin as required. That said, there are over-the-counter options as well. These exist in cases where an exchange traded option does not meet the specific needs of the counterparties (buyer and seller). Over the counter options can be defined as customized options (e.g., strike prices and expirations dates are not standardized), with no secondary market, that arise from a private transaction between a buyer and a seller.

~~25.54~~25.57 In the case of a call option transaction on equity, the purchaser acquires from the seller the possibility (option) to purchase corporate shares, at a fixed value, at some future point in time. If the stock price rises above the strike or exercise price, then the shares will likely be purchased at the strike price. The purchaser can claim an additional capital gain on the shares if he sells them, or he can hold them if expecting further stock market appreciation. However, if the option is not exercised then the seller benefits by retaining the premium. Buyers and sellers of such options may have different short and long-term expectations about the future value of the corporate shares.

~~25.55~~ **Warrants** are a form of options. They are tradable instruments giving the holder the right but not the obligation to buy, under specified terms for a specified period, from the issuer of the warrant (usually a corporation) a certain number of units of an underlying asset such as shares or bonds or exchange traded funds. Warrants are frequently attached to preferred shares (or bonds), allowing the issuer to pay lower dividends (interest rates). For example, detachable warrants are usually issued in conjunction with bonds (warrant linked bonds) which allows the bond issuer to offer a lower coupon rate. Warrants on equity-linked instruments give investors the right to buy the underlying shares at a discount to the issue price. There are also currency warrants based on the amount of one currency required to buy another and cross-currency warrants tied to third currencies. ~~Warrants also include covered warrants. A covered warrant gives the holder the right but not the obligation to buy or sell an underlying asset (either financial, or non-financial such as commodities) at an agreed upon price for a specified period of time or on a specified date.~~

~~25.56~~25.58 Warrants can be traded apart from the underlying securities to which they are linked and therefore have a market value. The issuer of the warrant incurs a liability, which is the counterpart of the asset held by the purchaser. Although similar to other traded options, a distinguishing feature is that the exercise of the warrants can create new securities. This dilutes the capital of existing bondholders or shareholders, whereas traded options typically grant rights over assets that are already available.

~~25.59~~ Warrants also include covered warrants, which are issued without an accompanying security (bond or equity). A covered warrant gives the holder the right but not the obligation to buy or sell an underlying asset (either a financial asset, or a non-financial asset such as commodities) at an agreed upon price for a specified period of time or on a specified date.

## Credit derivatives

~~25.57~~25.60 The financial derivatives described in the previous paragraphs are related to market risk, which pertains to changes in the market prices of securities and commodities, interest, exchange rates, or other underlying items. Credit derivatives are financial derivatives whose primary purpose is to trade credit risk. They are designed for trading in loan and debt security default risk. Credit derivatives take the form of both forward-type and option-type contracts, and like other financial derivatives they are frequently drawn up under standard master legal agreements and involve collateral and margining procedures. There are three main types of credit derivatives: credit default swaps which are more of an option type instrument because of the fixed payments/premiums; credit default options; and, total return swaps, which is a forward type of contract.

~~25.58~~25.61 A **credit default swap** is a type of option; though either party can be a creditor or debtor. It is the

case where the purchaser pays a periodic fee to the seller in return for a cash ~~payment~~reimbursement by the seller in the event of a default by the debtor of the underlying instrument. These periodic payments made by the protection purchaser to the protection seller ~~is referred to as~~constitute transactions in financial derivatives (see paragraph 25.74) that arise from the credit default swap spread, which can be established as the yield differential between bonds and/or loans of different quality and similar maturity. A credit default swap is considered a type of safeguard against non-payment resulting from a credit event, such as a change in a borrower's capacity to meet payment obligations. The purchaser may be speculating that the debtor will default, while the seller takes an opposite position. In this way, this instrument transfers the credit exposure of fixed income products from one investor to another (counterparty) investor. The protection buyer benefits when there is a deterioration in the credit quality of the reference entity and the CDS spread increases; and the protection seller benefits when the credit quality of the reference entity improves and the CDS spread declines. In both cases, the value of the CDS adjusts accordingly. The CDS underlying asset may be loans, debt securities or securitized debt (asset-backed securities). And they are more useful in the context of longer-term debt securities, where the debtor's ability to repay is relatively more difficult to predict.

~~25.59~~25.62 A **credit default option** is an option to buy protection or sell protection via a credit default swap.

~~25.60~~25.63 A **total return swap** is a forward contract which is a modified equity swap. It is generally thought of as a credit derivative, even though it encompasses both credit and market risk. It constitutes a derivative contract where one party pays sums based on a floating or fixed interest rate and receives payments from another party based on the return of a reference item (bond, share, index). The returns include any gains or losses in the reference item's price as well as any coupon or dividends over the period. The swap allows one party (the buyer) to gain exposure to an asset without owning it, in exchange for taking on the risk associated with the reference item (market risk and or credit risk depending on the underlying item). The other party (the seller) eliminates risk with the underlying item but takes on the credit risk to which the first party may be subject (that is, the risk of the counterparty of the swap).

### Other derivatives, not elsewhere included

~~25.61~~25.64 Other derivative contracts include those that do not involve exposure to the risks noted above. These can include inflation-indexed, volatility, dividend, property, freight, weather, or any other derivative contracts with non-standard underlying items, which are developed for a particular client. This category can also include derivative crypto assets, which are derivative contracts that rely on cryptography and that can be exchanged peer-to-peer even if the underlying asset is not a crypto asset).

## 3. Overview of accounting for derivatives

### Valuation of stocks and flows

~~25.62~~25.65 This section can be supplemented by material in other manuals. Users are referred to the UN ECB Handbook Financial Production, Flows and Stocks in the System of National Accounts, for detailed examples, and the Monetary and Financial Statistics Manual and Compilation Guide.

#### *Derivative positions*

~~25.63~~25.66 All financial derivative positions should be reported at current market value. This differs substantially from the notional value behind the derivative contract, which is the current value of the underlying item in a derivative contract at any point in time. As a result, the notional values are much larger than the corresponding market values of the derivative contracts. For exchange traded derivatives, the market values can be readily observed. For over-the-counter derivatives, the values should be valued using market-equivalent prices. This allows for a proper assessment of total market and/or credit risk on a timely basis. It is also necessary to calculate any new margin requirements, based on the gains or losses associated with the contracts.

~~25.64~~25.67 A key characteristic of many derivative contracts is that the counterparties make commitments to

transact, in the future and at agreed upon prices, in underlying items. Therefore, the market price (or present value) of a derivative contract corresponds to the difference between the agreed upon contract price of an underlying item and the prevailing market price (or market price expected to prevail), appropriately discounted, for that item. For a swap the value is derived as the difference, appropriately discounted, between expected gross receipts and payments. For all derivatives, especially for options and warrants, the prevailing market price is the current market value. In the absence of prevailing market prices, the cost of buying out the contract is used. The accumulation of transactions should not be used to estimate positions. However, source data typically provide information on positions.

25.6525.68 Financial derivatives are reported on the balance sheet account, ideally on a gross basis as assets or liabilities – that is, as an asset in the case of a holding gain (potential cash inflow) or as a liability in the case of a holding loss (potential cash outflow). The market value of a forward-type contract or a credit default swap can switch from an asset to a liability position (and vice-versa) between reporting dates resulting from movements in the price of the underlying item. For example, if the value of a credit default swap becomes negative, it becomes a liability for the protection buyer (rather than an asset) and an asset for the protection ~~buyer~~seller (rather than a liability). More specific references to the balance sheet account and revaluation account follow in the discussion below.

### *Transactions and other flows*

25.6625.69 Financial derivatives transactions relate largely to those in options or to settlements for other types of derivatives. Transactions may take place between two parties directly, or through an intermediary. In the latter case, implicit or explicit service charges may be involved. In the former case, service charges may also be involved if one party is a financial institution. Arranging a financial derivative may also involve a set-up fee which should be shown as an explicit fee charged by the financial institution concerned and payable by the holder of the financial derivative. A financial institution may act as a market maker and sell the products with a spread between the bid and offer price. This spread margin is treated as a service charge as with other financial instruments. ~~For example, the~~ The premium paid to the seller of an option can ~~conceptually~~ be considered ~~to include~~ a service charge. However, it is usually not possible to distinguish the implicit service element. Any observable commissions paid to brokers or other intermediaries for arranging options, futures, swaps, and other derivatives contracts are treated as payments for services in the sequence of accounts.

25.6725.70 No investment income accrues on financial derivatives, and all payments are financial transactions (with holding gains/losses as required to reconcile opening and closing balance sheets). A premium may be charged at inception of contract (e.g., options), but forward-type contracts generally have a zero cost at initiation and therefore no value. This can change significantly over the course of a contract, giving rise to revaluations and some transactions. These are discussed briefly below, referencing major types of instruments.

25.6825.71 Transactions in derivatives may arise in a series of instances:

- a. At inception, if there is a cost (e.g., in the case of options, where the upfront premium is the acquisition of the derivative);
- b. during the life of the contract if there is a series of premiums (in the case of credit default swaps) or exchanges of cash flows in interest swaps;
- c. on secondary markets where existing contracts are bought and sold, such as with options;
- d. with ongoing servicing in the form of ~~non-repayable margin~~servicing/settlement payments (see ~~paragraph~~paragraphs 25.7974 and 25.82);
- e. and at settlement, where either a cash payment is made, or an underlying item is delivered.

25.6925.72 The value of most derivative positions emerges largely from revaluation. The initial value of a forward-type financial derivative is typically zero (no transactions recorded), but it acquires a value as soon as there is a change in the circumstances that the financial derivative is designed to address. At this point, a financial asset of one party and matching liability are recognized as a flow and recorded as a revaluation

generating a balance sheet position. Most of the subsequent changes in value are recorded in the revaluation account and on the balance sheet, ~~however.~~ For forward contracts, some fluctuations in value ~~are on the balance sheet can be~~ the result of transactions in margin (see paragraph 25.7679), which act to reduce the exposure of the derivative contract between both parties. For exchange traded contracts with active secondary markets, such as futures, transactions are frequent and holding gains and losses can be significant.

~~25.70~~25.73 In the case of options, ~~including credit default swaps,~~ the full price of the premium should be recorded as acquisition of a financial asset by the buyer and as incurrence of a liability by the seller in the financial account, with corresponding positions in the balance sheet account. ~~The timing of premium payments on options varies. Depending on the type of contract, premiums are paid when the contracts begin, or at fixed intervals for credit default swaps, or when the options are exercised, or when the options expire.~~ The value of an option at inception should be recorded at the full price of the upfront premium. ~~If the premiums are paid after the purchase of an option, the,~~ including credit default swaps if applicable (where if the present value of the protection leg is greater than that of the payment leg, the seller pays and upfront premium to the buyer). Sometimes the premium ~~payable is paid after inception of the contract (excluding ongoing servicing payments such as in the case of credit default swaps which are transactions in financial derivatives, as noted in paragraph 25.74) and, in that case, the value of the premium is recorded as an asset, under other at the inception of the contract in the same manner as if it had been paid but is shown as being financed by accounts receivable/payable, at the time the derivative is purchased, financed by other accounts receivable/payable from between the writer- and the purchaser.~~

~~25.71~~25.74 ~~Purchases~~Subsequent purchases and sales of options and futures ~~in the secondary market~~ are also to be recorded in the financial account- as transactions in financial derivatives. There can also be periodic cash settlement payments on forwards and swaps. Streams of net settlement payments under a swap or forward rate agreement contract (which might be described as interest in the contract) are not property income, and on a credit default swap (which might be described as premiums) are not fees. Rather, both are recorded as transactions in financial derivatives (refer to paragraphs 8.122 and paragraphs 12.131 to 12.135). If an option based on a financial asset is exercised ~~or if a commodity based option proceeds to delivery, at any point prior to expiration~~ the acquisition or sale of the underlying asset should be recorded at the prevailing market price in the appropriate ~~accounts~~instrument in the financial account with the difference between this amount and the amount actually paid recorded as transactions in financial derivatives. This can also occur before maturity for exchange traded contracts such as commodity futures or commodity options, giving rise to other accounts receivable/payable.

~~25.72~~25.75 Revaluations of both exchange-traded and over-the counter-derivative positions are based on the holding gains/losses associated with the contract, and these changes can occur over the life of the contract prior to maturity. These fluctuations are reported as assets or liabilities in the revaluation account of the other changes in assets and liabilities account, leading to new values on the balance sheet. For some contracts ~~with active secondary markets~~, holding gains and losses can be significant. For changes in value that arise from exchange rate fluctuations, it is useful to report these as supplementary details in the revaluation account.

~~25.73~~25.76 Derivative instruments record net settlement transactions at maturity- (excluding margin cash settlement payments, discussed in paragraph 25.82). This will involve the extinguishing of the derivative contract as a transaction along with corresponding transactions between the parties in other assets - typically cash, given that financial derivatives contracts are usually settled by net payments of cash. ~~This can occur before maturity for exchange traded contracts such as commodity futures, giving rise to other accounts receivable/payable.~~ Cash settlement is a logical consequence of the use of financial derivatives to trade risk independently or ownership of an underlying item. However, some financial derivative contracts, particularly involving foreign currency, are associated with transactions in the underlying item. Commodity-based contracts (e.g., commodity options) can also proceed to delivery and give rise to transactions in the underlying item. The delivery of the underlying commodity or asset should be recorded as a transaction in the relevant item (e.g., in goods or commodities) category at the prevailing market price, and the difference between the prevailing price and the price actually paid (times the quantity of the ~~commodity or asset~~underlying item) should be recorded as a transaction in financial derivatives.

~~25.74~~25.77 Two further activities worth noting in relation to financial derivatives are novation and portfolio compression. Novation is the replacement of an existing bilateral obligation with two new ones. For financial derivatives, this is where a bilateral contract between two parties is replaced by two bilateral contracts

between each of the original parties and a clearinghouse. One advantage of novation is that the clearinghouse middleman assumes the counterparty risk. Novation can also take place without a clearinghouse, where one participant transfers a contract to another party. The total value of derivative contracts increases with a novation activity because there is an additional contract involving a third party. Transactions are also recorded at the time of the activity but, for the original parties, extinguishing of the first contract is offset by a new contract with the same value. For the third party, whether a clearinghouse or not, new transactions are recorded.

~~25.75~~25.78 On the other hand, portfolio compression is the process of replacing a number of derivative contracts among participants with fewer new contracts. This, in turn, reduces the value of the overall investment, while maintaining the same risk and on a net basis. Net positions are also unchanged, although gross positions can be different. This process reduces both the total number of contracts in place and the aggregate notional values at risk. Portfolio compression can take place among two or more parties. Compression also results in transactions at the time of the activity by terminating the existing contracts and creating new contracts, sometimes with different counterparties.

## The treatment of margin on derivatives

~~25.76~~25.79 The provision of margin reflects market concern over counterparty risk and is a standard feature in financial derivative markets. The requirement of margin is a feature of many derivative contracts, (such as with futures, forwards, and often credit default swaps), which reflects the leveraged nature of most contracts alongside potential or actual obligations arising from the changes in value of the underlying item on which the derivative ~~contract~~instrument is based over the duration of the ~~derivative instrument.~~ Margins~~contract.~~ Margin balances are payments of adjusted by cash deposits and/or pledging of collateral relating to potential or actual obligations (see paragraph 25.81) or by cash payments (that cover many or most actual ~~or potential~~ obligations) under financial derivatives, (see paragraph 25.82), the latter especially common for futures as well as cleared over the counter forward contracts. If the margin balance falls below the minimum or “maintenance” margin, the investor receives a margin call which is a call for providing additional funds. ~~futures or other exchange-traded derivatives.~~ The funds transferred due to a margin call is referred to as the variation margin (sometimes also used to describe the margin call itself).

~~25.77~~25.80 A key role of the exchange is to organize trading so that default risk is minimized. ~~for exchange traded financial derivative contracts.~~ To achieve this, the exchange operates a clearinghouse which acts as a counterparty for all such contracts. The clearinghouse requires that both members of the exchange deposit ~~a dollar~~an amount per contract in an account upon entrance into the agreement. If the members of the exchange are acting on behalf of others, they will require a similar deposit from their clients. ~~Some~~Depending on the jurisdiction, some, or most, over the counter financial derivatives ~~also~~ require margin, ~~in.~~ In the case of cleared over the counter derivatives, ~~In these cases,~~ a clearinghouse, operating with the banks/brokers that facilitated the contract, requires that both parties to the transaction deposit an amount upon entrance to the agreement. This requirement will also be passed on to their customers if the facilitators act on their behalf.

~~25.78~~25.81 The initial margin placement may be made up of cash or interest-bearing securities. ~~These~~The margin placements are sometimes referred to as “repayable margins, and margin”, given that the funds remain under the ownership of the depositor who retains the risk and rewards of the amounts placed. ~~Repayable margins payments~~Margin placement transactions in cash are not the counterpart of transactions in derivatives; rather, they are the counterpart of transactions in claims (deposits) on the exchange or at another institution corresponding to the resulting margin balances. ~~Such claims are classified as deposits if the debtor’s liabilities are included in monetary aggregates’ broad money. Otherwise, they are included in accounts receivable/payable or as a loan. When repayable margin payments~~placements are made in pledged non-cash assets, such as securities, no entries are required because the entity on whom the depositor has a claim (the issuer of the security) is unchanged. In the case of a maintenance margin call (which can result from new contracts or holding losses on existing contracts), additional margin is required. These funds are not to settle a financial derivative contract and should not be recorded in transactions in financial derivatives.

~~25.79~~25.82 ~~For centrally cleared~~However, as noted above, financial derivatives can also be subject to cash settlement payments. For centrally cleared over the counter and exchange traded derivative contracts, gains or losses associated with changes in the value of the derivative, over the life of the contract, are frequently

applied to the margin account. ~~If the margin balance falls below the minimum or “maintenance” margin, the investor receives a margin call which is a call for providing additional funds. The cash transferred due to a margin call is referred to as the variation margin (sometimes also used to describe the margin call itself). This constitutes a non-repayable margin, and the entity that is responsible for the payment no longer retains ownership of the margin nor has the right to the risk and rewards of such ownership (such as the receipt of income or exposure to holding gains or losses). The funds transferred are typically transactions in deposits but can also be in loans or other accounts receivable/payable. Non repayable margin reduces a financial liability created under a financial derivative contract give rise to recurring settlement payments.~~ In organized exchanges, this ~~type of margin~~ is typically paid daily to meet the liabilities incurred from the daily (or intra-daily) marking of derivatives to market value. ~~In terms of transactions, a payment of a non-repayable margin~~ These settlement payments give rise to transactions in derivatives, reducing the financial liability created under a financial derivative contract loss. More specifically, the settlement payment is normally recorded as a transaction-based decline in the margin balance (e.g., currency and deposits) with a counter entry in the reduction in financial derivative liabilities; and the receipt of ~~a non-repayable margin~~ the funds is recorded as a transaction-based increase in the margin balance (e.g., currency and deposits) with the counter entry in the reduction in financial derivative assets. The counter entries constitute transactions in derivatives. For the party that has reduced or eliminated the financial derivative liability, it may be that any such cash settlement payment out of margin placement balances can also result in that party’s need to replenish the maintenance margin to whatever degree would be required after the transaction.

#### 4. Classification Presentation and presentation classification of derivative contracts

##### Presentation of derivatives in the SNA

###### Basis of recording

- 25.83 Asset and liability positions and related flows in financial derivatives should be recorded separately on the balance sheets. For certain contracts (forward-type contracts and credit default swaps) that have registered accumulated holding gains (with a positive market value) are to be shown as an asset; and contracts that have registered accumulated holding losses (with a negative market value) should be shown as a liability.
- 25.84 However, it may not always be feasible to record asset and liability positions and flows separately, because relevant source data are not available. This is particularly true for transactions. For example, in cases where several payments by both counterparties are made in a period when a derivative contract switches between an asset and liability position (e.g., forwards and swaps) gross recording may be impractical. In such cases, the alternative with net payments resulting in a reduction in liabilities for one party and a decrease in assets for the other party, thus consolidating a unit's assets and liabilities (often referred to as net reporting) is considered acceptable under certain circumstances. It should be noted, however, that this can give rise to asymmetries across sectors (depending on counterparties’ reporting). The resulting balance, at any point in time, is shown as an asset (if the balance is positive) or a liability (if the balance is negative).

##### **Classification of derivatives**

- 25.8025.85 Derivative contracts can be classified in various ways. One common classification is by **instrument**, with two broad groupings: forwards and options, with any further details by sub-instrument. For example, forwards can include exchange traded futures and over the counter forwards and swaps. One complication with the instrument breakdown is that some sub-instruments are hybrid types and may not fit cleanly into the two main groupings. Some other classifications can be considered. A **maturity breakdown by type of instrument** is another example of supplementary sub-instrument detail. A lesser used related sub-classification is **by delivery type**. That is, whether at the end of a contract there is cash delivery (in most cases) or physical delivery of the underlying item (e.g., a commodity).

- 25.8125.86 Another possible classification is by **trading venue**. This distinguishes between whether the instruments are exchange-traded or over-the-counter derivatives. Related to the trading venue classification is one based on **clearing status**. This would combine exchange traded contracts with cleared over-the-counter contracts in one category and non-cleared over-the-counter contracts in another category. Cleared over-the-

counter derivatives are those for which a clearinghouse party is involved and therefore margin is required. This classification would require a sub-category of cleared versus non-cleared for over-the-counter derivatives.

~~25.82~~25.87 A more appropriate classification, than those discussed above, is by **market risk** category. This includes foreign exchange, interest rate, equity, commodity, credit, and other derivatives. It is widely considered that such a breakdown provides more analytical value than the instrument classification. It also allows for a separate classification of credit default swaps. In practice, however, individual financial derivatives may straddle more than one risk category. For contracts that are simple combinations of exposures, it should be possible to identify and report in terms of the individual components. Those that cannot be broken down into separable risk components should be reported in only one risk category, determined by the underlying category that is the most significant. If there is doubt about the correct classification of multi-exposure derivative contracts, the allocation by risk component should be made according to the order of preference adopted by the Bank of International Settlements: Commodities, equities, foreign exchange, and single currency interest rate.

## ~~Presentation of derivatives in the SNA~~

### ~~Basis of recording~~

~~25.83~~ Asset and liability positions and flows in financial derivatives should be recorded separately on the balance sheets. Contracts that have registered accumulated holding gains (with a positive market value) are to be shown as an asset; and contracts that have registered accumulated holding losses (with a negative market value) should be shown as a liability.

~~25.84~~25.1 However, it may not always be feasible to record asset and liability positions and flows separately, because of data shortcomings. This is particularly true for transactions. As a result, a presentation which consolidates a unit's asset and liability positions is an acceptable alternative under these circumstances. The resulting balance, at any point in time, is shown as an asset (if the balance is positive) or a liability (if the balance is negative).

### ~~Classification details~~

~~25.85~~ The proposed recommended breakdown of financial derivatives emphasizes risk as the main classification should be broken down by type of market risk, as follows: By market risk category as the first supplementary item subclassification. The focus by derivative type (forwards, options, credit, other and hybrid derivatives) is a second supplementary subclassification, with detailed types of contracts, if possible. This information could be inserted underneath each classification for derivatives by market risk category or shown separately. Derivatives by venue and/or by clearing status are also supplementary and can be reflected in the derivatives by type detail. Cross-classification of derivatives by instrument, trading venue and clearing status is also considered a supplementary presentation.

~~25.86~~25.88 The first subclassification for financial derivatives, under AF7.1, financial derivatives includes contracts organized in the following groups: **Foreign exchange risk derivatives** (e.g., currency forward), **single currency interest rate derivatives** (e.g., interest rate swap), **equity risk derivatives** (e.g., options on corporate shares), **commodity risk** (e.g., commodity futures), **credit risk derivatives** (e.g., credit default swap), and **other risk derivatives**. Each category of **risk derivatives** is briefly discussed below:

~~25.87~~25.89 Foreign exchange derivatives involve the exchange of currencies in the forward market. They include all contracts involving exposure to more than one currency, whether in interest rates or exchange rates. They cover outright forwards, foreign exchange swaps, currency swaps (including cross-currency interest rate swaps) and currency options.

~~25.88~~25.90 Single currency interest rate derivatives are restricted to those deals where all of the legs are exposed to only one currency's interest rate. These are contracts related to an interest-bearing financial instrument whose cash flows are determined by referencing interest rates (or by another interest rate contract). They include forward rate contracts, single currency interest rate swaps, and interest rate options (including caps, floors, collars and corridors), but exclude contracts involving the exchange of currencies (e.g., cross currency swaps and currency options) and other contracts whose predominant risk characteristics is foreign exchange

risk.

~~25.89~~25.91 Equity derivatives where the return, or a portion of the return, is linked to the price of a particular equity or index of equity prices.

~~a. —Commodity derivatives, where the return, or a portion of the return, is linked to the price or to a price index of a commodity (e.g., precious metal, petroleum, lumber or agricultural products).~~

~~25.90~~25.92 Credit derivatives are contracts in which the payout is linked primarily to some measure of the creditworthiness of a particular reference asset. ~~The~~They specify ~~and~~an exchange of payments in which at least one of the two legs is determined by the performance of the reference asset. Payouts can be triggered by different events, including a default, a credit downgrade, or a stipulated change in the credit spread of the reference asset. Typical credit derivative instruments are credit default swaps, credit-spread forwards and options, credit event/default swaps, and total return swaps.

~~25.91~~25.93 Other derivatives (as noted in paragraph 25.59) are any other derivative contracts which do not involve exposure to foreign exchange, interest rate, equity, ~~commodity~~ or credit risk. They include, for example, inflation-indexed derivatives, volatility derivatives, commodity derivatives, property derivatives, or freight derivatives.

~~25.94~~ It is also encouraged to compile, as supplementary items, other breakdowns of derivatives. This includes by instrument (forwards, options, credit derivatives and other and hybrid derivatives) and by trading venue and/or by clearing status, as follows: exchange traded derivatives, over the counter derivatives, cleared derivatives, and non-cleared (over the counter) derivatives). It may also be considered useful to compile data on the currency composition of the notional values of the derivatives linked to foreign currencies.

## **D. Employee stock options**

### **1. Some preliminaries and terminology**

#### **Definition and terminology**

~~25.92~~25.95 As noted in Chapter 12 an employee stock option is an agreement made on a given date (the “grant” date) under which an employee may purchase a given number of shares of the employer’s stock at a stated price (the “strike” price either at a stated time (the “vesting” date) or within a period of time (the “exercise” period) immediately following the vesting date. This part of the chapter will examine these issues in more detail.

~~25.93~~25.96 While an employee stock option (ESO) has certain characteristics of a standard option or warrant on corporate shares (they are regular call options), it is in fact a different instrument that is used for specific purposes. An ESO is unlisted and not tradable (cannot be sold) or exchangeable, as it is specific to an employee’s compensation package. It is a particular form of income in kind, referred to as equity compensation, which reflects the practice of an employer giving an employee the option to buy stocks (shares) at some future date. The employee may choose to not exercise the option, for varied reasons; these might be the case either because the share price is now lower than the price at which they can exercise the option, or because they have left the employ of that employer and ~~so forfeits his~~ thus forfeiting the option in the process.

~~25.94~~25.97 The terms of the ESO are spelled out to the employee in a formal agreement. Typically, an employer informs his employees of the decision to make a stock option available at a given price (the strike price or exercise price) after a certain time under certain conditions. These may include that the employee is still in the enterprise’s employ or may be conditional on the performance of the enterprise or employee.

~~25.95~~25.98 The time of recording of the employee stock option in the national accounts must be carefully specified. This includes the “grant date” which is when the option is provided to the employee; the “vesting date” which is the earliest date that the option can be exercised; and the “exercise date” or “exercise period” which is when the option is either exercised or lapses. In some countries the permissible length of time between vesting and exercise date is quite long; in others it is short.

## Valuation

~~25.96~~25.99 The following is a brief description of how stock options are valued, taking accounting for the probability that not all the options are exercised. ~~The~~ IASB-IFRS accounting recommendations are that the enterprise derives a fair value for the options at grant date by taking the strike price of the shares at that time multiplied by the number of options expected to be exercisable at vesting date divided by the number of service years expected to be provided until the vesting date. This fair value is applied to the number of service years provided in each year to derive the cost to the firm in the year. The fair value per service year is adjusted if the assumptions about the number of options to be exercised alter.

~~25.97~~25.100 In the SNA, if there is neither an observable market price nor ~~an~~ a fair value estimate made by the corporation in line with the recommendations just given, the valuation of the options may be estimated using a stock options pricing model. These models aim to capture two effects in the value of the option. The first effect is a projection of the amount by which the market price of the shares in question will exceed the strike price at the vesting date. The second effect allows for the expectation that the price will rise further between the vesting date and exercise date.

## ESOs as financial assets

~~25.98~~25.101 Following vesting but before the option is exercised, the arrangement between the employer and employee has the nature of a financial derivative stock option for a period; however, it is shown in the financial accounts of both parties as “employee stock options”. The employee has an asset, and the employer has a liability. Once exercised, the ESOs are exchanged for company stock, often at different and higher values which can entail a cash outlay by the employee. The advantage of an ESO is that if or when the stock rises above the call option exercise price, the employee can acquire the enterprise’s stock at a discount. Once acquired, the employee can hold the stock in anticipation of further gains or dispose of it for a realized gain.

~~25.99~~25.102 The employer’s motive for an ESO is to provide staff with the incentive to help build the company’s success and share in the benefits of the success. As an aside, there are other types of arrangements where employers can achieve similar results with their staff, such as through stock appreciation rights or employee stock purchase plans.

~~25.100~~25.103 ESOs may also provide a benefit with respect to the recruitment and retention of staff, as well as offer certain taxation advantages. There are two further qualifications worth making: first, it is sometimes possible that the employer may buy back the options for cash instead of issuing shares; and second, it is also possible that multinational corporations may offer employees in one economy options on shares of their parent company in another country.

## 2. Accounting for ESOs

### Current accounts

~~25.101~~25.104 An estimate of the value of the ESO should be made on the grant date. This amount should be included as part of ~~compensation~~ remuneration of employees spread over the period between the grant date and vesting date, if possible. If this is not possible, the value of the option should be recorded at the vesting date.

~~25.102~~25.105 The following adapts a simplified version of the example in the UN-ECB Handbook Financial Production Flows and Stocks in the System of National Account. It is assumed that the ESO has a strike price of 30 and a fair value of 20 and that there are 5 employees. for a total value of 100. It is further assumed that the ESO compensation is spread over 2 consecutive periods, at 50 per period. This amount (50) would be included on the ~~uses~~ expenditures side of the corporation’s generation of earned income account as ~~compensation~~ remuneration of employees in each period. It would also be recorded in the households’ allocation of ~~primary~~ earned income account as ~~compensation~~ remuneration of employees in each period, as well as being reflected in the net saving balances.

~~25.103~~25.106 The costs of administering ESOs are borne by the employer and are treated as part of intermediate

consumption just as any other administrative functions associated with ~~compensation~~remuneration of employees. Although the value of the stock option is treated as income, there is no investment income associated with ESOs in the ~~primary~~earned income account.

### Accumulation accounts and balance sheet

~~25.104~~25.107 The value of the ESO in both periods (i.e., the vesting period and the exercise period) would be reflected in the net lending/borrowing balances. In the financial account, the acquisition of an asset of 50 by households in each of the first and second periods is matched by the corresponding liability increases of the employer. The corresponding amounts recorded on the balance sheet are 50 at the end of the first period and 100 at the end of the second period, respectively. Prior to vesting, ~~this is usually~~these amounts can be recorded as other accounts receivable/payable but ~~can~~would ideally be recorded as an ESO asset and liability in the broader financial derivatives category under F7.2 Employee stock options in the SNA.

~~25.105~~25.108 At vesting, if the entry is not already accounted for as an ESO, then there would be offsetting financial transactions, for the full amount of 100, to convert the other accounts receivable and payable into ESO assets and liabilities. These would also be reflected in the balance sheet account as an ESO over the exercise period.

~~25.106~~25.109 When the ESO is exercised following the vesting date, the stock price is assumed to be 50, in line with the grant value of 20 and the strike price of 30. Households record purchases of shares, for a total amount of 250 (50 times 5 employees), in the financial account, with the source of funding being drawing down their own liquid funds by 150 (such as deposits) and extinguishing the ESO of 100 (this value would be the difference between the market price of the equity and the price paid by the buyer for the equity). Corporations record a corresponding issue of shares of 250 and an extinguishing of their ESO liability entry, as well as a source of funds (such as deposits), in the financial account. In other words, exercising the ESO constitutes a set of financial transactions ~~and not a set of entries in the other changes in the volume of assets account~~. This change is also reflected in the closing balance sheet account with households' stock holdings now at 250 from the exercise of the ESO, and corporations' equity liabilities up by the same amount. In the end, households have acquired 250 in new equity from the prior period labour compensation of 100 and a further 150 injection of their own funds.

~~25.107~~25.110 In principle, any change in value between the grant date and vesting date should be treated as part of ~~compensation~~remuneration of employees while any change in value between vesting date and exercise date is not treated as ~~compensation~~remuneration of employees but as a holding gain or loss. In practice, it is most unlikely that estimates of the costs of ESOs to the employers are revised between grant date and exercise date. For pragmatic reasons, therefore, the whole of any increase between grant date and exercise date is typically treated as a holding gain or loss. An increase in value of the share price above the expected price at grant time is a holding gain for the employee and a holding loss for the employer and vice versa. If an ESO is not exercised before the end of the exercise period (e.g., due to being allowed to expire, or due to change in employment), then the associated ESO financial asset of the holder and liability of the corporation cease to exist and should be treated as other changes in the volume of assets and liabilities. Further, there are no adjustments to prior periods' ESO-related employee compensation.

### 3. Variations on employee stock options

~~25.108~~25.111 For clarity within the SNA, the term employee stock option (ESO) is used to include stock appreciation rights for that part that relates to employee compensation. However, there are a few types of activities that have some similarities in accounting with ESOs that amount to other means of rewarding employees that are related to shares in the company. ~~None of these and may be used in conjunction with ESOs. These~~ activities do not constitute ESOs, but they are briefly discussed so as not to confuse them with ESOs.

~~25.109~~25.112 The first is a variation on the use of stock options to reward employees is an offer extended to employees to purchase shares at advantageous rates under an employee share (stock) purchase plan. Employees are not obliged to accept the offer; however, if they do, the discount in the share value should be

treated as part of ~~compensation~~remuneration of employment. Similarly, if employees receive a benefit relating to the change in a company's shares but not shares themselves, this payment should be treated as part of the ~~compensation~~remuneration of employees. The second variation is the case of a firm contributing its own shares to the pension fund. This is usually termed an employee share plan or a stock ownership plan.

~~25.113~~ 25.113 The second consequence is the possibility that the enterprise pays for goods and services by using stock options, as well as offering these as part of the employee compensation package. When this happens, the value of the stock options should be estimated, if possible, by the value of the goods and services received in exchange. If this is not possible, similar valuation methods should be used as in employee stock options. services in the financial account. Such arrangements are usually referred to as share (stock) appreciation rights. For simplicity, within the SNA, the term employee stock options (ESOs) is used to include stock appreciation rights.

## E. Recording of flows associated with financial assets and liabilities

### 1. Introduction

~~25.114~~25.114 ~~Financial instrument stocks~~Disregarding transactions in financial instruments, stocks of financial instruments in the balance sheet account arise from the sectoral imbalances (net lending or net borrowing balances) in the sequence of current and capital accounts. These, in turn, give rise to net acquisition of financial assets or net incurrence of liabilities transactions in the financial account to build and adjust those stocks as required. This deficit or surplus of funds is largely intermediated through the financial corporations' subsectors, which meets the needs of investors and borrowers through their own stocks of financial assets and liabilities and investment activities, underlining the importance of the financial system to an economy. Chapters 12 and 14 discuss the financial account and balance sheet, respectively, with an emphasis on financial assets and liabilities. Chapter 29 discusses financial corporations.

~~25.114~~25.115 Holdings of financial instruments can give rise to various types of returns (e.g., interest and dividends), which are recorded as transactions in the ~~primary~~earned income account. Transactions in financial instruments and holdings of financial instruments may also give rise to fees charged by financial corporations, some explicit and some implicit, and included in their output measures.

~~25.114~~25.116 Financial assets and liabilities stocks also generate other flows – revaluations from holding gains and losses as well as volume changes, as discussed in Chapter 13. Revaluations of assets and liabilities tend to be a significant part of other flows, especially for marketable securities and instruments as well as financial instruments denominated in foreign currencies.

~~25.113~~25.117 All in all, non-financial and financial transactions, as well as other flows, determine the changes between opening and closing stocks on the balance sheets. The objective of this part of chapter 25 (as summarized in Figure 25.1) is to discuss, for each category of financial assets and liabilities, how and where changes in their values are recorded in the SNA and to discuss when some part of the transaction relating to a financial instrument is treated as a measure of the output of financial institutions. Before describing these flows in detail in the next section, it is helpful first to recall the characteristics of financial institutions, the type of flows that are associated with providing financial services as well as the sort of income and holding gains and losses associated with holding financial assets and liabilities.

**Figure 25.1: Indications of the flows associated with different financial instruments**

### The characteristics of financial institutions

~~25.114~~25.118 Within the SNA, the term “corporations” is used to describe institutional units providing both

financial and non-financial services- for the market. These are divided into two institutional sectors: financial corporations and non-financial corporations. Financial corporations are distinguished from non-financial corporations because they play a particular role in the economy. Some may issue deposits and facilitate means of payments between other units thus avoiding the need for barter. Some also provide the means whereby units seeking additional funds to finance capital formation, acquire financial assets or even for consumption can utilize the funding set aside by other units as saving. More generally, financial corporations are important for matching domestic non-financial investment with national saving and the external sector balance.

**Figure 25.1: Indications of the flows associated with different financial instruments**

25.11525.119 When considering the financial sector alone or in connection with other statistics such as monetary and financial statistics, it is usual to speak of financial institutions rather than financial corporations. No change in definition or coverage is implied by this change in terminology. When sub-sectoring the financial sector, as explained in chapter 5, a distinction is made between those financial corporations that are primarily involved in financial intermediation, which are called financial intermediaries, and other financial institutions.

25.11625.120 Financial intermediation characterizes the activity of matching the needs of borrowers with the desires of lenders. It is carried out by financial institutions preparing alternative sets of conditions under which clients can borrow and lend. These conditions allow for variations in the rate of return that may be expected from an investment (lending) with, often, higher returns associated with increased risk and/or the longer-term investment of funds. There are now very many, very diverse ways in which money can be borrowed and lent. Financial intermediation thus draws on the different expectations of borrowers and lenders. The act of financial intermediation is thus one of devising financial instruments that encourage those with savings to commit to lend to the financial institutions on the conditions inherent in the instruments so that the financial institutions can then lend the same funds to others as another set of instruments with different conditions. This activity encompasses financial risk management as well as maturity and liquidity transformation.

25.11725.121 ~~All financial~~ Financial intermediation ~~is for the SNA~~ market is typically carried out by financial corporations, with the possible exception of some financial services carried out by unincorporated enterprises classified in the households sector. However, some institutional units in the financial sector are not themselves intermediaries but simply provide services auxiliary to financial intermediation. For example, they may provide advice on borrowing and lending products and counterparts suitable for their clients, such as a mortgage broker or provide certain sorts of financial resources such as a foreign exchange bureau that exchanges one currency for another. These are the units described as financial auxiliaries.

25.11825.122 Financial institutions charge for the services they provide. The ways in which they charge for their services are not always obvious, or explicit. When a bank offers low-cost deposits, it only signifies that there are minimal explicit fees, not that there are no implicit fees. Fees may also be charged indirectly by means of charging those purchasing a financial asset more than the seller of the same asset receives. For example, dealers in foreign exchange typically buy and sell at different rates; the differences between those rates and the mid-point represent service charges paid by the customers. Further, interest rates on loans are typically higher than the costs of funding by banks (i.e., deposits); or, conversely, interest rates on deposits are lower than the risk-free interest at which banks may invest these funds (i.e., loans).

25.11925.123 It is not only the service charge that may have to be measured indirectly, but also in some cases the investment income. Bills and commercial paper are an offer of a fixed sum at some time in the future and the promise of this payment is sold at a discount. The increase in value accruing between the buying price and the redemption price is treated as interest in the SNA.

25.12025.124 The existence of implicit fees explains the difference between the terms used in financial markets (e.g., banking) and those used in the SNA. For example, the money paid by a bank on a deposit is described as interest by the bank but is not the amount recorded as interest in the SNA, because the amount paid by the bank is assumed to be a compound payment representing interest as understood in the SNA less the service charges levied on the depositor for the costs of operating the account. In the SNA, the terms bank interest

and SNA interest are used when it is necessary to distinguish the two concepts. Unless it is qualified as bank interest, the term interest in the SNA is to be taken as referring to SNA interest.

## Charging for financial services

~~25.121~~25.125 As noted above, the way in which financial institutions charge for the services they provide is not always as evident as the way in which charges are made for most goods and services. Several kinds of financial institutions do make explicit fees for the services they render. Other financial institutions may make implicit charges, either alone or in conjunction with explicit fees. For a discussion of the treatment of implicit and explicit service charges, see paragraphs 7.176 to 7.178.

~~25.122~~25.126 Explicit fees should always be recorded as payable by the unit to whom the services are rendered to the institution performing the service. If the services are rendered to a corporation or to government, the costs will form part of intermediate consumption. If they are rendered to households they will be treated as final consumption unless the financial service is performed in relation to an unincorporated enterprise, including the owning and occupying of a dwelling. Within the SNA, fees are not incorporated into the value of any financial asset even if their incurrence is necessary for the acquisition of the asset, nor do these fees affect the value at which transactions in financial assets take place in the market.

~~25.123~~25.127 Implicit charges for financial services have to be measured indirectly. The charges may be simply the difference between the buying and mid-price and between the mid-price and selling price as in the example of foreign exchange quoted above. (Each service should be calculated at the time of the transaction concerned so that holding gains and losses occurring between the time of the purchase and sale are not treated as services.) Other implicit charges may be combined with other transactions (or other flows) on a particular financial instrument. The service charge associated with borrowing and lending is one such example where it is combined with interest. As noted in Chapter 8 when the output of financial services is discussed, ignoring the implicit charges for financial services may lead to understating the output of the industry and sector.

## Investment income associated with financial instruments

~~25.124~~25.128 Most financial instruments give rise to investment income. Debt instruments such as Special Drawing Rights (SDRs) on the IMF, loans, most debt securities, deposits, and some unallocated gold accounts where the amount is repaid according to a fixed formula give rise to interest. (see paragraphs 8.119-8.130 for a more elaborated discussion of interest). All fees payable to the owners of securities used for securities lending or gold used for gold loans (whether from allocated or non-allocated gold accounts) should be recorded by convention as interest. The interest may have a component of implicit financial services on loans and deposits), if the unit providing the loan is classified as a financial institution. Equity and investment fund shares give rise to dividends, withdrawals from income of quasi-corporations, reinvested earnings on foreign direct investment, or investment income attributable to collective investment fund shareholders. ~~Except for other~~The SNA assumes that no interest is charged on accounts receivable ~~or~~/payable, ~~only~~except under extraordinary purposes for trade accounts (see paragraph 25.192). In addition, gold bullion, currency, non-interest-bearing deposits, financial derivatives and employee stock options never give rise to investment income. ~~For the sake of simplicity, the SNA assumes no interest is charged on other accounts receivable/payable~~ All fees payable to the owners of securities used for securities lending and to the owners of gold used for gold loans (whether from allocated or non-allocated gold accounts) should be recorded by convention as interest. The interest may have a FISIM component, separately identified, if the unit providing the loan is classified as a financial institution.

## Holding gains and losses on financial instruments

25.129 Holding gains and losses are recorded in the revaluation account irrespective of whether the gains and losses are realized or not. Chapter 13 contains a detailed discussion on revaluations.

~~25.125~~—In the normal course of events, loans and deposits at nominal value and denominated in domestic currency do not give rise to holding gains though there will always be real holding losses for the asset holder (holding

gains for the borrower) in the presence of inflation. ~~Securities~~ Debt securities denominated in domestic currency may be subject to nominal holding gains and losses, as changes in the market interest rate leads to changes in the present value of future coupon payments and redemption values, which are reflected in the market price. Such recording is made irrespective of whether the gains and losses are realized or not.

25.130 For equity and investment fund shares other than money market fund shares, nominal holding gains are common and may be substantial. Indeed, reaping potential holding gains is one main reason for investing in such instruments.

25.131 Financial instruments denominated in foreign currency(ies) are also subject to nominal holding gains, as the relevant exchange rates fluctuate.

## **Volume changes on financial instruments**

25.12625.132 Unlike non-financial assets, there are few items recorded in the other changes in the volume of assets and liabilities accounts for financial instruments. Two common ones are worth noting here. First, the monetization and de-monetization of monetary gold reserves is entered as volume changes, as the gold assets typically change from/to valuables (gold bullion). Second, loans that are deemed uncollectible, and that are not forgiven, are written-off and the values disappear from the asset boundary as volume changes. Refer to Chapter 13 for a detailed discussion on volume changes.

## **2. Recording flows in financial instruments**

25.12725.133 As explained above, both service charges and investment income flows may be combined with the costs of acquiring and disposing of financial assets and liabilities. This section of the chapter, therefore, examines each class of instrument in turn to identify what flows should be recorded in each case. Explicit fees are not covered in this section since even if they apply, their value is additional to the value at which financial assets change hands.

25.12825.134 There are three types of flows of relevance in this section; the implicit fees made by financial institutions; included in the production account (and the use of income account), different income flows included in the earned income account, and holding gains and losses included in the revaluation account. A summary of the types of flows that relate to each instrument is given in figure 25.1. Implicit fees are subdivided between those that appear as a margin between the purchase and selling price and those that represent a margin on interest paid and received ~~(FISIM)~~, specifically, financial intermediation services on deposits and loans. All income flows are investment income, and these flows are divided between interest, dividends, withdrawals from quasi-corporations, reinvested earnings on foreign direct investment and investment income attributed to investment fund shareholders. Only the instruments relating to insurance and pension schemes are excluded as the treatment of these schemes is described in Chapter 24. ~~Standardized guarantees are discussed in Section B of this chapter. Furthermore, more details~~ Details on Islamic finance are provided in Chapter 26.

## **Monetary gold**

25.12925.135 Monetary gold is gold to which the monetary authorities (or others who are subject to the effective control of the monetary authorities) have title and is held as a reserve asset. Monetary gold consists of two subcategories: physical gold bullion (including allocated gold accounts) and unallocated gold accounts, both of which are held by the monetary authorities (or other units authorized by them) as part of reserves. Although it may not be possible to publish these two subcategories separately for reasons of confidentiality, it is important to understand the different considerations that apply to each of them.

25.13025.136 Gold bullion takes the form of coins, ingots, or bars with a purity of at least 995 parts per thousand. Gold held as a valuable by commercial banks or as inventories by some specialized industries (for example, jewelers), may be indistinguishable from gold bullion or may be of a lower quality. Physical gold, excluding gold bullion included in monetary gold, whether gold bullion or not, can be referred to as commodity gold (since it is traded on commodity markets).

~~25.131~~25.137 Gold bullion may be sold by one monetary authority to another in another country. In such a case the exchange is recorded as an exchange of financial assets only. In all other cases, the gold is reclassified as commodity gold and thus a valuable held by the monetary authority (and is no longer part of reserves) and is then sold as commodity gold. The reclassification is recorded in the other changes in the volume of assets and liabilities account as demonetization of gold. If the gold is sold abroad it will feature in exports and imports of the countries concerned. When commodity gold is sold, there may be a trade margin attached to it. When a monetary authority seeks to increase its holdings of monetary gold through purchases of commodity gold, a reverse path is followed. The gold is acquired initially as commodity gold either from a domestic unit or from abroad and is subsequently reclassified to monetary gold as monetization in the other changes in the volume of assets and liabilities account.

~~25.132~~25.138 There is no interest earned on gold bullion held as a valuable, but it is subject to nominal and real holding gains and losses as the gold price changes. However, a fee or interest can be earned when gold is lent out ~~(i.e., gold swaps)-, such as in the case of gold swaps which are collateralized loans and earn interest.~~ Monetary gold under such reverse transaction agreements, should be excluded from reserve assets (see paragraph 12.46).

~~25.133~~25.139 Unallocated gold accounts are treated as foreign currency deposits unless they are held by the monetary authorities as part of foreign reserves. Unlike gold bullion, unallocated gold accounts have counterpart liabilities. Because the unallocated gold accounts classified as monetary gold must be held as part of foreign reserves, the counterpart liability is necessarily held abroad. The counterpart liability will not be treated as part of monetary gold in the counterpart country. (Assets held abroad as part of foreign reserves are generally not identified as such within the liabilities of the partner country.) If a monetary authority acquires an unallocated gold account to be treated as reserves from a non-resident non-monetary authority entity, it is recorded first as an acquisition of a foreign currency deposit and then reclassified to monetary gold as a change of classification in the other changes in the volume of assets and liabilities account. Removing an unallocated gold account from reserves is recorded as, first, a change in classification from monetary gold to a foreign currency deposit and then as a disposal of the deposit.

~~25.134~~25.140 Unallocated gold accounts attract interest and a service charge and are also subject to nominal and real holding gains and losses as the gold price alters.

## Special Drawing Rights (SDRs)

~~25.135~~25.141 SDRs are international reserve assets created by the IMF and allocated to its members to supplement existing official reserves. SDRs are held only by the monetary authorities of IMF members and a limited number of international financial institutions that are authorized holders. SDR holdings represent unconditional rights to obtain foreign exchange or other reserve assets from other IMF members. Participants may hold more or fewer SDRs than their allocation as a result of transactions in SDRs between participants, or between participants and prescribed holders. Holdings of SDRs by an IMF member are recorded as a financial asset, while the allocation of SDRs is recorded as an incurrence of a liability of the member receiving them (see 12.49 and 12.50). The IMF's SDR Department pays interest on SDR holdings to each member and levies interest charges on SDR allocations of each member at the same rate. Participants incur a small annual levy to cover the operational costs of the SDR, which should be treated as explicit fees. Data on the interest rates payable are available regularly from the IMF. Since the value of the SDR is based on a basket of five major currencies, the value of SDRs is always subject to nominal and real holding gains and losses. Sometimes, new allocations of SDRs may be made; when this occurs, the allocation is recorded as a transaction.

## Currency

~~25.136~~25.142 Currency consists of notes, coins as well as digital currencies (i.e., central bank digital currency) that are of fixed nominal values and are normally issued or authorized by the central bank or government. Notes and coins are the simplest financial asset to record since for domestic currency, no implicit service charges, investment income or nominal holding gains and losses are recorded. Under inflation, though, the holder of notes and coins suffers real holding losses. The cost of producing the physical notes and coins is

recorded as production and collective final consumption of government expenditure and not netted against the receipts from issuing central bank, depending on who produces and issues the currency. Central bank digital currency might be subject to explicit fees.

~~25.137~~25.143 Foreign currency (the liabilities of non-resident units) should be recorded in the national balance sheets converted to a value in domestic currency using the exchange rate relevant for the date of the balance sheet. This value is subject to nominal and real holding gains and losses as the exchange rate of the foreign currency relative to the domestic currency fluctuates. As noted above, there is usually a service charge associated with acquiring or disposing of foreign currency.

## Deposits and loans

~~25.138~~25.144 ~~Financial Intermediation Services Indirectly Measured (FISIM)~~Implicit financial services on loans and deposits concern the implicit service charges related to financial intermediation associated with loans and deposits held with financial intermediaries (excluding central banks). Paragraphs ~~8.xxx~~7.177 to ~~8.xxx~~7.186 describe the basic principle of ~~FISIM~~these implicit financial services and explain the need to make the distinction, referred to above, between interest as understood by the banks ~~holding~~issuing deposits and ~~issuing~~holding loans and the investment income flows recorded in the SNA. Preferably, a single reference rate should be applied to the level of loans and deposits denominated in domestic currency to determine the SNA interest flows to be recorded. The difference between these flows and bank interest are recorded as service charges payable to the banks by the units holding the deposits or loans. This applies to both resident and non-resident units and to deposits and loans held with resident and non-resident units. For clarity, the term bank interest is used to indicate the apparent interest as quoted by a financial intermediary to their customer; the term SNA interest is used for the amount recorded in the SNA as interest, that is the level of loans and deposits multiplied by the reference rate chosen. For deposits with banks, the service charge is equal to SNA interest less bank interest; for loans the service charge is equal to bank interest less SNA interest. At a minimum, it is probable that different reference rates should be used for every currency in which non-resident loans and deposits are denominated. For reasons of feasibility, it is recommended to use, for the calculation of imports and exports of ~~FISIM~~implicit financial services on loans and deposits, at least two groups of currencies (typically, the two most material in terms of non-resident loans and deposits).

~~25.139~~25.145 No exclusion is made for lending of own funds. Although the act of lending own funds, and the charging of SNA interest ~~is~~does not ~~give rise to implicit~~productive activity, the SNA considers that there is a service charge associated with lending. A person borrowing from a bank is unaware whether the amounts borrowed are of intermediated funds or come from the bank's own funds and no difference in the service charges applied should be made. Similarly, if a person borrows from a money lender, there is a service charge payable, as the loan is made from own funds.

~~25.140~~25.146 It is not always simple to determine whether positions between banks should be classified as deposits or loans because the parties are unclear, or one party considers it a loan and the other a deposit. To ensure symmetry, all interbank positions, other than securities and accounts receivable/payable, are classified under deposits. It is assumed that the inter-bank rate at which banks borrow and lend to one another is usually such as to meet the criteria for a reference rate. (In some cases, it may be appropriate to use the inter-bank rate as the reference rate.) For this reason, it may often be appropriate to assume that there is no ~~FISIM~~implicit financial services on loans and deposits associated with inter-bank lending and borrowing within the national economy. In some instances, such as for major financial hubs, it may often be appropriate to assume that there is also no ~~FISIM~~such implicit financial services associated with inter-bank lending and borrowing with non-resident financial intermediaries. ~~FISIM is also not assumed for~~There are no implicit financial services on loans and deposits ~~with~~for central banks.

~~25.141~~25.147 The outstanding balance on a credit card or on an account with a retailer is often subject to interest. These outstanding balances should be classified as loans, not other accounts receivable or payable. ~~FISIM is~~Implicit financial services on loans and deposits are calculated on them if the unit providing the loan is classified as a financial intermediary.

~~25.142~~25.148 Repurchase agreements (repos) are classified as giving rise to deposits or loans depending on whether they are or are not included in the national measure of broad money- (see 12.80 to 12.85 for a

discussion of reverse transactions). They thus give rise to interest that may have a ~~FISIM~~ an implicit financial services component. In addition, they have fees associated with their initiation.

~~25.143~~25.149 There are no nominal holding gains and losses on deposits and loans expressed in domestic currency (whether these are held by residents or non-residents). With any inflation, there will be real holding losses on assets denominated in domestic currency. There may be nominal and real holding gains and losses on deposits and loans denominated in other currencies or held as unallocated gold accounts (or similar accounts in other precious metals).

~~25.144~~25.150 Any charges made by a financial institution for operating a bank account, a fee for cashing a cheque or for withdrawing money from an automatic teller machine are all treated as explicit fees.

~~25.145~~25.151 The special case of non-performing loans and how they should be treated in the SNA is discussed in Chapter 14.

## Debt securities

25.152 Debt securities are negotiable financial instruments serving as evidence of debt, usually with active secondary markets. The characteristics common to most include: an issue date and issue price, a redemption (or original maturity) date, a redemption price or face value, as well as, at any point in time a remaining maturity; a coupon (interest) rate that the issuer pays to the holder of debt securities (which may be fixed or variable), as well as coupon dates on which the issuer pays the coupon interest installment to the securities' holders.

25.153 Debt securities cover those with fixed interest rates or variable rates of return. There are a number of specific types of fixed interest rate debt securities, including stripped bonds (separate trading of interest and principal) and convertible bonds (into equity). Variable interest rate securities have their interest and/or principal payments linked to a reference item. These would be indexed debt for which either the coupon payments or the principal payments or both are linked to a price index (or inflation). These are discussed separately below (see paragraphs 25.169-25.178).

~~25.146~~25.154 In terms of recording the associated flows in fixed income debt securities, there are four broad types of debt securities. The first is where the amount payable at the end of the period for which the security exists is the same as the initial amount paid for the security but there are associated "coupons" that entitle the holder to payments of interest, at fixed ~~or variable~~ rates, at intervals during the life of the instrument.

~~25.147~~25.155 The second type of security is one where no intermediate payments are made but the issue price differs from the redemption price, such as where the security is issued at a discount ~~or a premium (the latter including deep-discounted bonds and zero-coupon debt securities)~~. Take the case where the issue price is lower than the redemption price, with the security issued at a discount. The issue price is equal to the redemption price discounted to the date of issue at the appropriate rate of interest that could be earned on a deposit of similar characteristics. The increase in value of the security during its life is treated as interest accruing to the holder of the security that is "reinvested" in the security to increase its value.

~~25.148~~25.156 The third type of security is a hybrid of the two other forms noted above; the initial value is less than the redemption value but there are also attached coupons. In certain circumstances, if the coupons represent a rate of interest higher than that prevailing in the market for similar securities at time of issue, the security may be offered at a price higher than the redemption price (but only the face value will be redeemed at maturity).

~~25.149~~—The fourth type is perpetual debt where only coupon payments to perpetuity are present. It is a debt security with no maturity date, and the issuer does not have to redeem the principal amount.

~~25.150~~25.157 ~~Irrespective of the cash flow structure of the security, interest on debt securities can be defined as follows: the increase in the present value of the instrument's future cash flows discounted with the interest rate prevailing at the time of issuance (debtor approach), after subtracting any financial transaction.~~

## *Service charges associated with securities*

~~25.151~~—For securities, the interest calculated according to the coupon or as the increase in value of the security is

recorded in the SNA as such without adjustment for a service charge. However, there is normally a service charge associated with the acquisition of a security on initiation and with the disposal and acquisition of a security at any point during its life. These service charges are identified as being the difference between the buying (bid) and selling (ask or offer) price quoted for each security and the mid-price. The bid and offer prices should be those applicable to the individual buyer and seller since these may vary according to the quantity being transacted or other factors. ~~However, this treatment is only if financial institutions/traders apply this charge associated with the acquisition of a security.~~

~~25.152~~25.158 Suppose an instrument is bought for 102 and subsequently sold for 118 on the secondary market (both values including accrued interest) even though there has been no change in the rate of interest (and hence of the value of the instrument due to holding gains and losses). At first sight, it seems that interest of 16 should be recorded. However, suppose the mid-price on purchase was 100 and on sale was 120. The correct recording would be to show interest of 20 payable by the issuer of the security to the holder with a purchase of services of 4 payable by the holder to the dealer in securities. Ignoring the bid-ask spread understates interest and ignores the brokerage services provided by the financial institutions that buy and sell securities.

### *Accrued interest*

~~25.153~~ ~~In general, the interest on debt securities can be seen as the increase in the present value of the security's future cash flows discounted with the interest rate prevailing at issuance (using the SNA debtor approach) once any financial transaction has been subtracted.~~

### Interest on discounted securities

~~25.154~~25.159 There are two ways in which the value of a discounted security can be determined during its life when the prevailing interest rate is different from the rate prevailing when the security was issued. The debtor approach is the perspective of the unit issuing the security and the creditor approach is the perspective of the unit holding the security. The first option, called the debtor approach, is to continue to use the rate prevailing on initiation throughout the instrument's life. The alternative, the creditor approach, is to use the current rate to estimate the value of interest between any two points in the instrument's life.

~~25.155~~25.160 Suppose a debt security is offered at 90 with a redemption value of 100 (i.e., zero-coupon instrument). If the discount (interest) rate does not change during its life, interest will accrue steadily throughout. Suppose, though, that the interest rate falls when the instrument has reached a value of 95. Because the redemption value is now discounted by a smaller factor, the value of the security increases, say to 97. Both the creditor and debtor approach would record interest of 5 in the period before the interest rate decline. Under the creditor approach, this increase in value of 2 from 95 to 97 is treated as a holding gain and only the subsequent rise to the redemption value of 100 is treated as interest. Thus, over the whole life of the instrument it has given rise to interest of 8 and a holding gain of 2 for the creditor (and a holding loss for the debtor).

~~25.156~~25.161 In the SNA, the debtor approach is used for interest. Under this approach, the interest accruing in the period before the interest rise is still 5 but so is the interest in the period after the interest rate rise. Adding this level of interest to the value of 97, which includes the holding gain of 2, when the rise occurred would give a value of 102 at the redemption date. Since this value is too high, a holding loss of 2 must be recorded for the creditor (and a holding gain for the debtor). Thus, over the whole life of the instrument there is interest of 10 with an initial holding gain of 2 (when the interest rate changed) offset by the later holding loss of 2. The holding loss occurs steadily between when the holding gain was recorded and the redemption period. The rationale for using the debtor approach is that the debtor, the issuer of the security, is not liable to make the payment until the security matures and from his perspective it is appropriate to treat the total amount of interest as accruing steadily over the life of the security.

### Interest on bills, commercial paper and similar instruments

~~25.157~~25.162 Bills and other short-term paper are short-term securities that give the holder (creditor) the unconditional right to receive a stated fixed sum on a specified date. They are issued and traded in organized

markets at a discount that depends on current market short-term interest rates and the time to maturity. Most bills mature after a period ranging from one month to one year.

~~25.158~~25.163 As the instrument approaches maturity, its market value increases because there is less discounting applied to it. This increase in value, in common with the increase in the value of any asset due to the unwinding of a discount factor, is treated as income in the SNA. For financial assets, the income is recorded as interest.

~~25.159~~25.164 Let the price paid for a bill at its time of issue and after excluding the service charge be  $L$ ; this represents the amount of funds that the purchaser (creditor) provides to the issuer (debtor) and measures the value of the initial liability incurred by the issuer. Let the face value of the bill be  $F$ : this represents the sum paid to the holder of the bill (the creditor) when it matures. The difference,  $F-L$ , or discount on the bill, measures the interest payable over the life of the bill.

~~25.160~~25.165 Bills and other short-term paper are traded on money markets at values that gradually rise to reflect the interest accruing on the bills as they approach maturity. The increase in the value of a bill due to the accumulation of accrued interest does not constitute a holding gain because it is due to an increase in the principal outstanding and not to a change in the price of the asset.

### Interest on bonds and debentures

~~25.161~~25.166 The nominal value of a debt security accrues interest in accordance with the debtor approach. Bonds and debentures are long-term securities that give the holder the unconditional right to:

- A fixed or contractually determined variable money income in the form of coupon payments; or
- A stated fixed sum on a specified date or dates when the security is redeemed; or
- Both (a) and (b). Most bonds fall into this category.

~~25.162~~25.167 When a bond is issued at a discount, the difference between the face value, or redemption price, and the issue price constitutes interest that accrues over the life of the bond, in the same way as for a bill. However, as accounts are compiled for time periods that are typically much shorter than the life of the bond, the interest must be distributed over those periods. The way in which this may be done is explained below.

### Zero-coupon bonds

~~25.163~~25.168 Zero-coupon bonds are long-term securities that are similar to bills. ~~They~~They can be issued as single payment debt securities with no coupon payments, sold at a discount from face value. They can also be created from fixed rate debt securities by stripping them of the coupons (i.e., stripped bonds, often created by securities dealers but sometimes by the issuer) thus separating them from the final principal payment of the security and trading the coupons independently. Zero-coupon bonds do not entitle their holders to any fixed or variable money income but only to receive a stated fixed sum as repayment of principal and accrued interest on a specified date or dates. When they are issued, they are usually sold at a price that is substantially lower than the price at which they are redeemed on maturity. Let  $L$  equal the issue price and  $F$  the redemption price, so  $F-L$  is the value of the interest receivable and payable over the life of the bond. This interest has to be distributed over the years to its maturity. One possible method is to assume that interest at a rate of  $r$  is credited at the end of each year at an annual rate that is constant over the life of the bond, so that the final value  $F = L(1 + r)^n$ .

~~25.164~~25.169 The interest rate,  $r$ , is given by the following expression  $r = (F/L)^{1/n} - 1$  where  $n$  is the number of years from the time of issue to maturity. The interest accruing during the course of year  $t$  is then given by  $rL(1+r)^{t-1}$  where  $t = 1$  at the end of the first year.

~~25.165~~25.170 The interest accruing each year is effectively reinvested in the bond by its holder. Thus, counterpart entries equal to the value of the accrued interest must be recorded in the financial account as the acquisition of more bond by the holder (creditor) and as a further issue of more bond by the issuer (debtor).

### Other bonds, including deep-discounted bonds

~~25.166~~25.171 Most bonds pay a fixed or variable money income and may also be issued at a discount or, possibly, a premium. In such cases, the interest receivable by the holders of the bonds has two components:

- a. The amount of the money income receivable from coupon payments each period; plus
- b. The amount of interest accruing each period is attributable to the difference between the redemption price and the issue price.

~~25.167~~25.172 ~~The~~The interest rate should be the at which the present value of future interest and principal payments equals the issue price of the bond. However, the accrued interest can be approximated by separating the two components, so that the second component is calculated in the same way as for zero-coupon bonds, as described above. In the case of deep-discounted bonds, most of the interest accruing is attributable to the difference between the redemption price and the issue price. At the other extreme, some bonds offer an income stream in perpetuity and are never redeemed.

### Index-linked securities

~~25.168~~25.173 Another type of debt securities covers variable interest rate securities. Index-linked securities are financial instruments for which the amounts of the coupon payments (interest) or the principal outstanding or both are linked to a general price index, a specific price index, the price of a commodity, an interest rate, or an exchange rate index. Different treatments are recommended for the recording of transactions depending on the type of index used to uprate the level of principal to which the interest is linked and on the currency in which the interest and principal are denominated.

~~25.169~~25.174 The indexation mechanism links the amount to be paid at maturity or coupon payments or both to indicators agreed by the parties. The values of the indicators are not known in advance. For debt securities with indexation of the amount to be paid at maturity, they may be known only at the time of redemption. As a result, interest flows before redemption cannot be determined with certainty. For estimating interest accruals before the values of the reference indicators are known, some proxy measures have to be used. In this regard, it is useful to distinguish the following three arrangements:

- a. indexation of coupon payments only with no indexation of amount to be paid at maturity,
- b. indexation of the amount to be paid at maturity with no indexation of coupon payments, and
- c. indexation of both the amount to be paid at maturity and coupon payments.

~~25.170~~25.175 The principles described below for index-linked debt securities apply to all index-linked debt instruments.

~~25.171~~25.176 When only coupon payments are index-linked, the full amount resulting from indexation is treated as interest accruing during the period covered by the coupon. It is most likely that by the time data are compiled for a reporting period, the date for the coupon payment would have been passed and hence the value of the index is known. When the date for the coupon payment has not been passed, the movement in the index during that part of the reporting period covered by the coupon can be used to calculate the interest accrual.

~~25.172~~25.177 When the amount to be paid at maturity is index-linked, the calculation of interest accruals becomes uncertain because the redemption value is unknown; in some cases, the maturity time may be several years in the future. Two approaches can be followed to determine the interest accrual in each accounting period.

- a. Interest accruing in an accounting period due to the indexation of the amount to be paid at maturity may be calculated as the change in the value of this amount outstanding between the end and beginning of the accounting period due to the movement in the relevant index.
- b. Interest accruals may be determined by fixing the rate of accrual at the time of issue. Accordingly, interest is the difference between the issue price and the market expectation, at inception, of all payments that the debtor will have to make; this amount is recorded as interest accruing over the

life of the instrument. This approach records as income the yield-to-maturity at issuance, which incorporates the results of the indexation that are foreseen at the moment the instrument was created. Any deviation of the underlying index from the originally expected path leads to holding gains or losses which will not normally cancel out over the life of the instrument.

~~25.173~~25.178 While the first approach (using the movement in the index) has the advantage of simplicity, interest includes all changes and fluctuations in the value of the amount to be paid at maturity in each accounting period due to the movement in the relevant index. If there is a large fluctuation in the index, this approach may yield negative interest in some periods even though market interest rates at the time of issue and current period may be positive. Also, fluctuations behave like holding gains and losses. The second approach (fixing the rate at the time of issue) avoids such problems, but the actual future cash flows may differ from the initially expected cash flows unless ex ante market expectations are exactly met. This means that interest for the life of the instrument may not be equal to the difference between the issue price and redemption value.

~~25.174~~25.179 The first approach works well when a broad-based indexation of the amount to be paid at maturity is used (for example a consumer price index) as such indexation is expected to change relatively smoothly over time. However, the first approach may give counter-intuitive results when the indexation of the amount to be paid at maturity combines motives for both interest income and holding gains (for example, a commodity price, stock prices, or gold prices). Therefore, when indexation includes a holding gain motive, typically indexation based on a single, narrowly defined item, the second approach is preferred, otherwise the first approach should be used for the measurement of interest accrual.

~~25.175~~25.180 When both the amount to be paid at maturity and coupon payments are indexed to a broad-based reference item, interest accruals during an accounting period can be calculated by summing two elements: the amount resulting from the indexation of the coupon payment (as described in paragraph ~~47.276~~25.171), that is attributable to the accounting period, and the change in the value of the amount outstanding between the end and beginning of the accounting period due to the movement in the relevant index (as described in paragraph ~~47.277~~25.172(a)). When both the amount to be paid at maturity and coupon payments are indexed to a narrow index that includes a holding gain motive, interest accruals for any accounting period can be determined by fixing the yield-to-maturity at issuance.

~~25.176~~25.181 Debt instruments with both the amount to be paid at maturity and coupon payments indexed to foreign currency are treated as though they are denominated in that foreign currency; interest, other economic flows and stock levels for these instruments should be calculated using the same principles that apply to foreign currency denominated instruments. Interest should accrue throughout the period using the foreign currency as the currency of denomination and converted into the domestic currency using mid-point market exchange rates. Similarly, the amount outstanding should be valued using the foreign currency as the unit of account with the end of period exchange rate used to determine the domestic currency value of the entire debt instrument (including any accrued interest) in the international investment position. Changes in the market value of debt securities due to exchange rate movements or interest rate changes are treated as revaluations.

~~25.177~~25.182 As with other securities, the interest accruing as a result of indexation is effectively reinvested in the security and these additions to the value of the security must be recorded in the financial accounts of the holder and issuer.

## **Equity and investment fund shares**

~~25.178~~25.183 The financial service charges levied on transactions in equity and investment fund shares are calculated in the same way as for debt securities as the difference between the financial intermediary's selling price and the mid-price and between the mid-price and the intermediary's buying price: (refer to paragraphs 7.189-7.194). They are treated as implicit fees.

25.184 The investment income from corporate equity takes the form of distributed income of corporations. For corporations, the distributed income is in the form of dividends. For quasi-corporations, the investment income is withdrawals from income of quasi-corporations. As noted in chapter 8, dividends or other withdrawals from corporate income are recorded as investment income at the time the shares start to be quoted ex dividend. A different recording is made for extraordinarily large dividends (super dividends) that are out of line with recent experience regarding the amount of income available for distribution to the owners

of the corporation- (see paragraphs 8.136-8.137, 12-98-12.100 and 30.137). Any excess distribution is to be recorded as a withdrawal of equity (recorded in the financial account) and not as part of investment income.

~~25.179~~25.185 However, for foreign direct investment companies, all ~~distributions to non-resident shareholders of dividends payable are treated as earned income, including dividends sources from accumulated reserves from past earnings are recorded as dividends, except for redistributions arising from, unless they relate to the sales of financial or non-financial assets. In addition, The resulting difference in treatment on super dividends between domestically-controlled corporations and foreign direct investment enterprises, is considered an acceptable inconsistency that is in line with the different treatment of retained earnings of foreign direct investment enterprises, for which the retained profits are treated as being distributed in the form of reinvested earnings on foreign direct investment and reinvested in the relevant company. Chapter 30 discusses the case of exceptional dividends of public corporations. (see paragraphs 8.141-8.145 and 12.100).~~

~~25.180~~25.186 For investment funds, the income element comes in the form of investment income attributable to collective investment fund shareholders. In the SNA, these include dividends distributed to shareholders and retained earnings attributed to shareholders. Therefore, the full value of the investment income earned is shown as being distributed to the shareholder in the allocation of ~~primary~~earned income account with reinvestment of the retained earnings portion recorded in the financial account. However, if an investment fund is also a foreign direct investment enterprise, the reinvested earnings are recorded before the remaining investment income is distributed to investment fund shareholders.

~~25.181~~25.187 As noted earlier, there may be considerable holding gains and losses, both nominal and real, on equity and investment fund shares.

~~25.182~~25.188 The entries in the financial accounts relating to acquisitions of equity conceptually contain two distinct types of transactions. One is the exchange of equity and investment fund shares between institutional units. Because the transactions are valued at mid-price, total acquisitions must be equal to total disposals. The net effect, therefore, is to show the change in composition of the holders of shares by institutional sector and with the rest of the world. The second type of transaction included in the financial account is the receipt of any reinvestment of earnings and the counterpart of the outflow recorded under investment income payable by corporations. In calculating the revaluation element between opening and closing balance sheet, care must be taken to exclude the reinvestment of earnings term.

## Financial derivatives

~~25.183~~25.189 Issues relating to financial derivatives are discussed in Section C of this chapter.

## Employee stock options

~~25.184~~25.190 Issues relating to employee stock options are discussed in Section D of this chapter.

## Other accounts receivable or payable

~~25.185~~25.191 Other accounts receivable or payable are, essentially, accrual adjustments typified by trade credit and advances. Trade credit refers to the case where goods and services have been delivered but payment has not yet been received. Advances refer to payment for work-in-progress for which prepayment has been made but the products are not yet delivered. The means of financing payment, such as the use of credit cards, is not included here; the balance on the cards is treated as a loan and payments such as interest or overdue fees are recorded as for loans.

~~25.192~~ In the normal course of events, there is no interest charged on trade credit. However, when the time gap becomes unusually long and the amount of trade credit extended is very large, the conclusion may be that implicitly an interest fee has been charged. In such extreme cases, the actual payment or payments should be adjusted for accrued interest in order to arrive at the correct value of the asset transferred. Such adjustments are not recommended for normal trade credit.

~~25.186~~25.193 Other accounts receivable or payable denominated in domestic currency can have no nominal holding gains and losses but may have real ones. Any items denominated in foreign currency may have both nominal and real holding gains and losses.

## Chapter 26: Islamic Finance

### BPM7 Chapter 17 – Islamic Finance

#### A. General overview

##### 1. Background

- 26.1 Islamic finance is distinguishable from traditional finance in several ways, in relation to both financing and insurance activities. Islamic financial institutions, as well as financial institutions with Islamic windows that offer both conventional finance and Islamic finance, are bound by Shari’ah principles. The principles and rules of Shari’ah (or Islamic law) include prohibitions on *Riba* (usually translated as interest), *Gharar* or uncertainty (sometimes translated as “excessive uncertainty”), *Maysir* (gambling), as well as short sales or financing activities that are considered harmful to society. Islamic insurance follows these same principles and is further based on the notion of mutual assistance.
- 26.2 As a result, in economies in which Islamic finance is prevalent, financial corporations have developed specific forms of financing arrangements that are consistent with these principles. In addition, Islamic financial standard setting bodies, including the Accounting and Auditing Organization for Islamic Financial Institutions (AAOIFI) and the Islamic Financial Services Board (IFSB), have developed standards on accounting, auditing, and related regulatory standards and frameworks, to promote greater harmonization of Islamic finance reporting practices across countries.
- 26.3 The historical development of the System of National Accounts, external sector statistics, and other macroeconomic statistics have largely reflected the predominance of conventional financial structures and terminology. Given the rapid growth of Islamic finance in recent years, as suggested by studies and the Islamic Finance Development Indicator (IFDI), it is significant enough to affect the quality of different areas of macroeconomic statistics in several countries. This situation can affect the international comparability of these statistics. To address this, this chapter provides guidance on the statistical treatment of Islamic finance focusing on the national accounts and external sector statistics. More general guidance on financial corporations is provided in Chapter 29.

##### 2. Outline of the chapter

- 26.4 This chapter presents guidance to properly account for Islamic finance and insurance arrangements in the national accounts and external sector statistics. In doing so, it elucidates by instrument the special types of financing arrangements (sales-based contracts, lease-based contracts, equity-based contracts, or profit/loss sharing) that characterize Islamic finance. It reviews distinct operations of Islamic finance and insurance and addresses issues such as the nature of income on certain Islamic financial instruments (included among deposits, loans, debt securities), the sector classification of Islamic financial institutions, the measurement of output, including FISIM, the treatment of Islamic insurance-like business as well as the instrument classification of select Islamic financial arrangements. This chapter also briefly clarifies the concept of economic ownership in the case of Islamic Finance. The structure of the chapter is as follows: Part B reviews financial institutions and sectoring; Parts C and D provide guidance on the measurement of output and income, respectively; Part E presents Islamic financial arrangements, and how these are reflected in macroeconomic financial instruments; and Part F covers economic ownership.

#### B. Islamic financial institutions and sectoring

##### 1. Some basic features of Islamic finance

- 26.5 Important differences exist between conventional and Islamic finance. Islamic finance must follow certain “Shari’ah” ~~legal~~ standards, hence it is often called “Shari’ah-compliant”. The general principles of Islamic finance are: the prohibition of collection and payment of interest or other predetermined returns on investments; the encouragement of investment in real economic activities or trading in goods and services

for profit; sharing rewards and risks between parties involved; the avoidance of profiting from trading in financial assets or “using money to make money”; the discouragement of excessive uncertainty, which may prohibit the use of many types of financial derivatives; and the prohibition on the financing for certain activities that are forbidden by Islam, such as alcohol or drugs. In addition to commercially driven activity, Islamic principles also emphasize the importance of charitable giving, whether through the mandatory welfare due (or *Zakah*) or voluntary charity (*Sadaqah*). Both forms of giving can (but do not have to) be implemented through a type of endowment trust known as a *Waqf*.

- 26.6 To adhere to these principles and to simultaneously accommodate the financing of economic activity, Islamic financial corporations have developed various financing arrangements that are mapped to more generic financial instruments ~~(discussed in Section E, though there are some references below)~~. These financing arrangements are often based on trading models or profit and loss sharing models involving underlying real non-financial assets. ~~Economic ownership of any non-financial assets and changes in economic ownership (discussed in Section F) are fundamental to the compilation of the macro-economic statistics.~~ The recording of such non-financial assets may be reflected on the balance sheet of the Islamic financial institution or an entity which it owns when the (legal) ownership is acquired but this may not be the case for economic ownership as applied in the sequence of economic accounts. ~~can change rapidly afterwards by allocating the non-financial assets to the users of such assets.~~ Economic ownership of any non-financial assets and changes in economic ownership are discussed in Section F and are closely related to the characteristics of the financing instruments discussed in Section E.
- 26.7 In addition, Shari’ah-compliant activities should be segregated from non-compliant activities and funds (i.e., not following Shari’ah principles). This gives rise to some specific treatments. First, the financial statements of Islamic windows of conventional financial institutions are separated from their regular financial activities. Further, off-balance sheet restricted investment accounts of banks and other depository corporations which comply with Islamic finance accounting standards are to be classified as separate institutional units.
- 26.8 Second, there is a distinctive arrangement in which a charitable institution contracts with a fund manager to establish a dedicated, open-ended asset **Waqf Fund** managed according to Shari’ah principles, to which the public can make donations by “purchasing” units of the fund. The charitable institution is the beneficiary of the fund – that is, it is the economic owner of all the units of the fund. Under the agreement, the fund will reinvest or distribute specified amounts of the profits to the beneficiary, and it will charge fund management fees. The donor’s investment in the fund constitutes an irrevocable donation to the beneficiary, and the function of the fund is to provide financial management of the beneficiary’s portfolio of assets. These types of funds are also required to keep a complete set of accounts and constitute institutional units.
- 26.9 Third, there are various schemes in different countries for supporting or enabling pilgrims to save for, or to undertake the Islamic pilgrimage (or *Hajj*). The term **Hajj Fund** is used to describe the case of a market enterprise that undertakes, as a significant part of its activities, the management of long-term savings open to individuals intending to undertake the Hajj pilgrimage in compliance with Shari’ah principles. Such funds are considered as institutional units if they are legally established entities with an autonomous management and keep a complete set of accounts and are classified separately within the financial corporations’ sector. For Hajj savings to meet the conditions of deposits, it is likely that the fund would be a regulated deposit-taking entity (such as a bank or similar entity) with the principal value of the deposit typically protected to some degree. This may not be the most common scenario in many countries, where they are usually treated as non-money market investment funds. Although a **Hajj Fund** might undertake certain secondary non-financial activities, such as the provision of travel, accommodation and related services to pilgrims planning for the Hajj, these activities are expected to be far less significant than its financial activities. Such non-financial activities would normally involve a separate institutional unit outside of the fund.

## 2. Islamic banking and other financial activity, including sectoring

- 26.10 The following guidance focusses on the subsector classification of Shari’ah-compliant financial institutions within the financial corporations’ sector. These subsectors may also include conventional financial institutions as described in Chapter 29. The central bank (S121) and pension funds (S129) are not explicitly discussed below, as these are not specific to Islamic finance except perhaps for some of their investments (discussed in Section E).

## Deposit-taking institutions except the central bank (S122)

### *Organizational considerations*

- 26.11 This subsector is dominated by banks and can include both Islamic banks and other depository corporations, as well as conventional banks and other deposit-taking institutions with Islamic windows. **Islamic banks and other depository corporations** manage funds received to produce returns through investments or financing of transactions for customers. Such operations are sometimes described as *Mudarabah* transactions, the customer is a capital provider, and the financial institution is the entrepreneur (*Mudarib*) that invests the capital. The main inflows include **unrestricted funds** (discussed in Section E) that are commingled with other bank funds, in the same way as deposits in conventional banks. However, unrestricted funds are invested in Islamic financial instruments.
- 26.12 On the other hand, **restricted funds** are managed separately by the bank and segregated from other funds received and typically treated as off-balance sheet – that is, excluded from this subsector. The contracts under which these accounts are created do not give the bank authority over decisions regarding the use and distribution of the funds it receives from account holders. Rather, the bank can only make decisions on the administration and management of the accounts. The only link between the bank's accounts and the off-balance sheet restricted investment accounts is the share of investment income from these investment accounts (as *Mudarib*), which is recorded as a single item in the bank's income statement. Restricted funds, while part of the Islamic banks' business, are almost always treated as a separate institutional unit and included among investment funds.
- 26.13 **Islamic windows of conventional banks and other depository corporations** that accept deposits are also confined to invest the deposits in Islamic financial instruments only. The funds provided under such contracts have the characteristics of deposits, and they provide financing to borrowers using various Islamic financial instruments. Conventional banks are required to maintain a full set of accounts, including a balance sheet, for their **Islamic windows**. They are also obliged to have a Shari'ah Supervisory board, and may have an independent management separate from that of the conventional banks that run them. The reason for this is that the management of the windows requires the existence of a Shari'ah Council as part of its mission to ensure that the funds are not mixed with those funds of the conventional banks. Accordingly, Islamic windows in these cases are considered as institutional units independent of the conventional banks, but within the depository corporation's subsector.

### *Basics relating to sources and uses of funds*

- 26.14 Unlike conventional banking, there is no common interest rate (nor interest rate ladder) applicable to Islamic deposits that determines the depositors' returns. Islamic banks and Islamic windows of conventional banks offer Islamic deposit accounts that are closely parallel to conventional accounts, but the banks are also heavily funded by accounts in which returns/losses are shared between the bank and the depositor/investors. Under a profit-sharing model (i.e., participation account), an Islamic bank can withhold part of the depositors' net profits as a profit equalization reserve. Under SNA accrual rules, these profits should be treated as distributed and subsequently reinvested into the reserve. The depositors in these arrangements therefore acquire a component of the bank's equity or a different type of bank liability.
- 26.15 Diverse financial instruments, discussed in Section E, can be thought of as sources and uses of funds. Sources of funds are used to generate revenues in different ways - financing of sales, leasing, fees, equity participation, or investment. Some instruments do not have conventional bank equivalents. The returns to Islamic banks and windows on their financing and investments are not guaranteed, but rather depend on the success or failure of their ventures. Returns (and sometimes losses) are divided between the bank and the depositors based on the specific types of Islamic financial instruments used.

## Investment funds (S123 and S124)

- 26.16 Islamic Investment funds are collective investment schemes that issue shares or units to the public, and that are split into two subsectors within the financial corporations' sector. **Money market funds** (MMFs) are invested primarily in Islamic bank deposits. **Non-money market investment funds** (non-MMF), invest in a wider range of Islamic securities.
- 26.17 As noted above, the off-balance sheet **restricted investment accounts** which comply with Islamic finance accounting standards are classified as non-MMF investment funds. This is because the cash of the account holders are placed in an investment fund which is managed independently from the Islamic bank, through which these funds are channeled. In addition, a complete set of accounts for the investment fund, including the financial position which shows the equity of the account holders, is maintained. These restricted Islamic accounts should be treated as investment funds because the clients' money is held in segregated investment funds with any losses borne by the providers of the funds, except if these are due to breach of trust or misconduct by the units managing the funds. Furthermore, like conventional investment funds, these accounts distribute the profits from investments to investors in proportion to the value of their investments.
- 26.18 Collectively organized **Hajj Funds** are also allocated to the non-MMF subsector, provided the general conditions for this classification are met. These conditions include that they are legally established entities with autonomous management, and that they maintain a complete set of accounts. These funds, in concert with their long-term saving character, are not restricted to financial investments and savers bear the risks and rewards of the investments' performance.

### Other financial intermediaries except insurance corporations and pension funds (S125)

- 26.19 Islamic investment banks (that do not accept deposits) and investment companies are classified as other financial intermediaries. These entities typically provide Sharia'ah -compliant (advisory) investment banking services, such as structured finance on large projects or financial leasing (such as *Istisna'a* or *Ijarah*), investment placement activities, raising funds in equity and debt markets (often from joint *Mudaraba*), as well as trade finance (often *Murabaha*). Entities involved in installment sales (such as *Bai Muajjal-Ajef*) may also be classified in this subsector.

### Financial auxiliaries (S126)

- 26.20 **Takaful (insurance) operators** often constitute the main Sharia'ah-compliant business to be classified as financial auxiliaries. These entities (see paragraphs 26.25-26.26 and 26.44) manage and administer **Takaful (insurance) funds** on behalf of the participants by charging fees to cover their costs. They do not take economic ownership of the assets and liabilities of these funds. Financial auxiliaries may also relate to managers of investment funds, but not the assets they manage.

### Captive financial institutions and money lenders (S127)

- 26.21 **Waqf Funds** are a religious/charitable endowment, with the donated assets held by a charitable trust. A Waqf is a charitable institution that contracts with a fund manager to establish a dedicated Waqf Fund, which is open to the public to make donations by purchasing units of the fund. This reflects the fact that the beneficiary is the sole client and that these vehicles are like endowment funds. The financial instrument classification is that the beneficiary has an *Other equity* (F519) claim on the assets of the fund. Purchases of units in the fund by donors should be recorded as miscellaneous current transfers (D75) by donors to the beneficiary. These funds are classified as captive financial institutions.
- 26.22 This subsector can also include any Sharia'ah-compliant money lenders.

## 3. Insurance Corporations (S128)

- 26.23 There are some parallels between conventional and Islamic insurance (*Takaful*) and re-insurance (*Re-*

*takaful*). At the same time, there are notable differences in the business arrangements. **Takaful** and **Retakaful funds** are included in the insurance corporations' subsector, alongside conventional insurance companies and Islamic windows of conventional insurance companies. *Takaful* and *Retakaful funds* share characteristics with insurance and reinsurance in the SNA, as they collect contributions (which can be considered as the equivalent of premiums in conventional insurance) from participants and have reserves which belong to them. Islamic windows are also included in this subsector, as separate institutional units, given that they maintain segregated financial statements for this activity. In the case of *Light Takaful*, where the arrangements are less complex and do not have to be based on *Tabarru* principles, there is no segregation of operators from funds as is the case with conventional insurance. As noted above, **Takaful operators** with segregated financial statements are included among financial auxiliaries.

### Some basic features of Islamic insurance

- 26.24 In accordance with Islamic finance principles, **Takaful** business arrangements avoid uncertainty (sometimes translated as “excessive uncertainty”), gambling and predetermined interest-based investments. The term *Takaful* means “mutual guarantee”. Islamic insurance can therefore be defined as the process in which a group of people — that is, the participants — who face certain risk(s) agree that each of them contributes a specific amount (based on cooperation) to a non-profit fund that is to be used for compensating anyone of them and/or their beneficiaries for the potential loss encountered if the risk in question materializes. In a such an arrangement, the contract is based on **mutual assistance** (*Ta'awun*) and **reciprocal donation** (*Tabarru'*), rather than the conventional commercial relationship between an insurance company and a policyholder. In conventional insurance the insurer contracts to provide protection (incurs an obligation) against certain losses by leveraging the accumulated premiums paid by the policyholder (insured), including the returns on investment. In contrast, the “participants” in a **Takaful** scheme are considered simultaneously as the insurer and the insured, since the contributions into the **Takaful fund** belongs to the participants and the operator just manages on their behalf.
- 26.25 Islamic insurance is distinguished by two types of contractual relationships. The first is the underlying contract used among the group of participants to govern their relationship on the basis of cooperation and solidarity. Members of the group agree to renounce a certain amount of their contribution paid to a **Takaful fund** as a donation in order to provide mutual indemnity to any fellow participant who suffers a loss covered under the policy. In other words, the group of participants agree to guarantee each other and make contributions to the fund instead of paying premiums to cover themselves individually. The fund is the account established by the company (**Takaful operator**) as the insurance entity to receive (own) the contributions and oversee the reserves and the returns on investment.
- 26.26 The second is the contractual relationship between the group of participants and the **Takaful operator** appointed by the participants to manage and invest the funds for them. The company is not a typical insurer that takes on a liability. In fact, the operator/manager corporation is usually not part of the insurance sector, but rather part of financial auxiliaries. Generally, the operator manages the relationship and maintains separate accounts with respect to the claims (rights) and obligations of the policyholders. Both the operators and the funds maintain separate accounting records, to conform to Islamic finance accounting standards. However, there is one exception to this rule in the case of *Light Takaful*, which presents consolidated financial statements and looks more like conventional insurance arrangements.
- 26.27 The **Takaful** arrangements can encompass several types of structures that govern the relationship, such as profit sharing, payment of fees, return, or a combination of these elements. When a contract involves profit sharing, it is a combination of a *Tabarru'* contract and agency and/or a profit-sharing contract. For the various **Takaful** structures, it is important to emphasize that contributions, returns on investment and the resulting surplus belong to the participants collectively – that is, the returns on investment of contributions belong to the policyholders as a group, after deduction of the administrator's share. Therefore, any surplus can be distributed among participants or given to charity. If claims paid from the fund exceed the amount of premiums, the participants should increase their contributions. The policyholders make the contributions, receive protection (indemnities) against the materialization of risk that has been insured, and can also receive a share of surplus.

## Takaful types

- 26.28 Takaful business types cover general plans and family plans. **General Takaful** provides protection against material loss or any form of damage on a short-term basis (akin to non-life insurance). **Family Takaful** offers a combination of protection and long-term savings, usually covering a period of more than one year. In general, **Family Takaful** is deemed to be a composite plan offering both life and non-life insurance schemes unless specific regulation requires that these schemes be registered separately.
- 26.29 **Retakaful** is an extension that supports **Takaful** business activities as a form of reinsurance based on Islamic finance principles. It aims to mitigate the risks of business loss of Takaful business and to increase the capacity of direct insurance, in particular for high value properties. Considering the relatively small and still developing **Retakaful** domestic market in many Islamic economies, this could lead to a significant cross-border trade in such activities. In many economies, the domestic **Takaful** and **Retakaful** industry is likely to provide services to non-residents. Conversely, resident units can also purchase these same services from non-resident providers. This implies the need to account for such transactions in the external sector statistics.

## Takaful models

- 26.30 The underwriting surplus in **Takaful** arrangements is the amount calculated as the excess of total premium contributions of the policyholders-participants during the financial period over the total indemnities in respect of claims incurred during the period, net of **Retakaful** and after deducting and changes in technical provisions. The surplus should be disposed of in a way that serves the common interest of the participants such as accumulation of reserves, reduction of the contributions, charitable donations and/or distribution among the participants. This also depends on the adopted business model that defines whether the surplus should be transferred only to participants, shared with operators or retained in the fund.
- 26.31 Various **Takaful** models have been designed according to the underlying contracts signed between the participants and the operator, which first and foremost defines how the latter is compensated for the management of the takaful fund. Four main business models are distinguished:
- **Mudaraba-based Takaful**: the operator is ensured a share of profits generated from the investments of takaful funds;
  - **Wakalah-based Takaful**: the operator is paid a fee as a percentage of participants contributions;
  - **Wakalah-Mudaraba-based Takaful** or hybrid model: The operator is ensured both a fee as a percentage of contributions and a share of profits; and
  - **Waqf Takaful**: In contrast to the previous models, provides surplus which is not transferred to the participants but is retained in the **Takaful fund** by the operator.
- 26.32 In general, the business models adopted for **Family Takaful** differ from those offering only **General Takaful** in terms of disaggregation of the fund into the Participants' Risk Fund (PRF) and Participants' Investment Fund (PIF). In family arrangements, participants contribute to the common pool of funds of which a portion is invested as PIF for the purpose of investment and/or savings; and the other part of contribution is allocated to the PRF to meet claims by participants on the basis of mutual assistance or protection intended, settle **Retakaful** charges, or allocated to reserves.

## C. Output of Islamic financial institutions

### Introduction

- 26.33 The methods to calculate the output of Islamic financial institutions depend on how they are allocated to institutional sectors given their financial activities. Methods can include explicit fees, sum of costs, implicit financial services on loans and deposits~~financial intermediation services indirectly measured (FISIM)~~, or a combination of approaches. This section first discusses Islamic financial institutions excluding Islamic insurance, and then turns to Islamic insurance.

## 1. Measuring output of Islamic financial institutions (excluding Islamic insurance)

- 26.34 There are different methods used to measure output across the suite of Islamic financial institutions. Some of these employ the methodology for implicit financial services on loans and deposits, in part or in whole, to account for the implicit services provided. This approach, as it applies to Islamic finance is discussed below.

### **Methodology for implicit financial services on loans and deposits indirectly measured (FISIM) methodology in Islamic Finance**

- 26.35 The implicit financial services on loans and deposits methodology ~~concept of Financial Intermediation Services Indirectly Measured (FISIM)~~ for Islamic depository institutions parallels that of conventional financial institutions (see the discussion in paragraphs 7.179-7.188). This reflects the fact that, for some types of financial institutions, explicit service charges alone may not account for the full value of their services. Part of the compensation for the provision of services may be implicitly included in the difference between the returns on the funds provided to those that require funding and the returns on the funds provided by those with surplus funds. In the process of intermediating funds between parties with surplus funds and those that require funding, the relevant financial institutions provide services to both parties. The methodology for implicit financial services on loans and deposits provides a way to measure the services that are not explicitly charged for.

### *Reference rates and instrument scope*

- 26.36 The general approach is that it is also possible to determine a reference rate, ~~also~~ in the case of Islamic implicit financial services on loans and deposits ~~FISIM~~, which reflects a service-free rate and can be used to derive the service element on deposits and loans with varying characteristics. More specifically, in line with conventional banking, the implicit financial intermediation services provided by Islamic deposit taking corporations can be measured as the difference between the return rate paid to banks by borrowers and the reference rate plus the difference between the reference rate and the return rate actually paid to depositors. The term “return” is used to describe the broader interest-alternative returns on (non-equity) Islamic financial instruments (discussed in Section D).
- 26.37 This approach could be augmented by using different reference rates ~~may need to be used~~ for conventional and Islamic Shari’ah-compliant finance, in recognition of different risk profiles. Whatever the case, different reference rates should be applied for at least two groups of currencies (national and foreign currency) in cross-border transactions of Islamic deposits and loans – that is exports and imports of such implicit services ~~FISIM~~. The rate should be taken from the financial markets of the home market of the currency.
- 26.38 With respect to the issue of one or more reference rates, the objective testing results (conducted in 2023) with a select group of Islamic countries generally indicated that the estimates of nominal implicit financial services on loans and deposits and their annual growth rates did not differ significantly between conventional and Islamic finance. Thus, while the principles of Islamic finance prohibit the payment of interest, the nature of financial intermediation services of conventional and Islamic deposit-taking and lending seems to be broadly similar. Accordingly, it is recommended that only one reference rate be used to calculate implicit financial services on loans and deposits which are in the same currency, unless there is evidence to suggest that a different reference rate should be used to calculate implicit financial services on Islamic deposits and loans (see paragraph 7.183).
- 26.3826.39 These Islamic implicit services ~~FISIM~~ applies to total loans and total deposits (where relevant), rather than applying a more complex instrument-by-instrument approach. The latter was considered given that some Islamic instruments pay no investment income (see Section E below for a description of Islamic financial instruments).

## Measures of output for different types of Islamic Financial Institutions

~~26.39~~26.40 The various methods to measure output for Islamic Financial Institutions are summarized below. In the case of implicit financial services on loans and deposits ~~FISIM~~, the terminology reflects that of investment income (discussed in Part- D).

### *Central bank (S121)*

~~26.40~~26.41 For the Central bank (S121), monetary policy services, supervisory services and other services (financial stability, managing the payments services) are collective services. ~~As such, they are calculated as the sum of cost.~~ Central banks do not undertake intermediation services in the traditional sense. Central banks are atypical financial intermediaries which take on liabilities and engage in lending, but for the purpose of monetary policy and other public functions. ~~Intermediation services employ the FISIM methodology to estimate output. As a result, all of their services are considered non-market output, and they are calculated at the sum of costs (see paragraphs 7.165-7.169). To the extent that there are other services offered, such as supervisory services, explicit fees are used for market output and sum of costs approach is used for non-market output.~~

### *Deposit-taking corporations except the central bank (S122)*

~~26.41~~26.42 Deposit-taking corporations (S122) include Islamic banks and Islamic windows in conventional banks. In these cases, financial intermediation services are estimated as a combination of explicit fees and commissions (direct services) and the implicit financial services on loans and deposits FISIM methodology for implicit services. For the latter, the services on loans and deposits are calculated as follows:

$$\text{FISIM} = (r_L - rr) \times Y_L + (rr - r_D) \times Y_D, \text{ where,}$$

$r_L$  - the lending return rate

$r_D$  - deposit return rate

$rr$  - reference rate

$Y_L$  - average stock of loans

$Y_D$  - average stock of deposits

### *Money market and non-MMF Investment funds (S123 and S124)*

~~26.42~~26.43 In the case of both Shari'ah-compliant **Money market funds (S123)** and **Non-money market investment funds (S124)**, the output is treated in the same way as conventional investment funds. Therefore, output is estimated as the sum of various fees that these funds charge investors on transactions and positions. This includes purchase and redemption fees, exchange fees, account fees, and operating fees. However, for **Hajj Funds** and off-balance sheet restricted investment accounts output is measured as sum of costs, except in the case of implicit services FISIM on any loans on the financial statements such as *Murabaha* or *Ijarah* (see Section E for a discussion of Islamic financial instruments) may need to be calculated.

### *Other financial intermediaries except insurance corporations and pension funds and Shari'ah-compliant money lenders (part of S127 below)*

~~26.43~~26.44 Islamic investment banks and investment companies are included in **Other financial intermediaries (S125)**. For these types of institutions, output includes both explicit and implicit fees. In addition, for any Shari'ah-compliant money lending services included in **Captive financial institutions and money lenders (S127)**, measures of output combine explicit charges and implicitly measured financial services (IFS). For these types of financial institutions, the latter service element can be calculated as follows:

$IFS = (r_L - rr) \times Y_L$ , where  
 $r_L$  - the lending return rate  
 $rr$  - reference rate  
 $Y_L$  - average stock of loans

### *Financial auxiliaries (S126)*

~~26.44~~26.45 For **Financial auxiliaries (S126)** engaged in the management of Shari'ah compliant investments and funds brokerage, such as **Takaful funds** and investment funds, output is measured as the explicit fees charged to clients. For example, the fees payable by the **Waqf Fund** to the fund manager are classified as the output of this financial subsector. In the case of **Takaful operators** included in this subsector, the explicit fees approach is also used. Output is equivalent to the *Wakalah* fees they charge to administer the funds and/or the share of profits earned from the investment of those funds, depending on the structure.

### *Captive financial institutions and money lenders (S127)*

~~26.45~~26.46 For other Sharia'ah compliant institutional units included in **Captive financial institutions and money lenders (S127)**, output is measured as explicit fees or sum of costs. In the case of **Waqf Funds** in this subsector, output is typically measured as the sum of costs. Although the associated fees are costs that are contractually payable by the fund rather than by the beneficiary, they are shown as payable by the beneficiary to the fund because they are payable out of profits (with **Waqf Fund** profits as property income to the beneficiary). For money lenders the implicit financial services on loans are calculated as noted above (26.43).

## **2. Islamic Insurance output**

~~26.46~~26.47 The services provided diverge from those provided by conventional insurance, reflecting the fact that Islamic insurance processes are arranged differently than those of conventional insurance. The Islamic service component would be identified under the *Takaful* contract and different options may be considered depending on the business model adopted. In addition, the output of operators and funds reflect that they are separately classified as institutional units, except in the case of **Light Takaful**.

~~26.47~~26.48 **Takaful operators** manage, administer and invest the funds on behalf of the participants by charging fees to cover their costs. In this case, output is measured as the *Wakalah* fees they charge to administer **Takaful funds** and/or the share of profits earned from investing these funds, as noted above under financial auxiliaries.

~~26.48~~26.49 For **Takaful/Retakaful funds**, including both family and general plans, output is measured as the sum of costs. This is the *Wakalah* fees they pay to takaful operators and/or the share of profits payable to takaful operators plus any other intermediate consumption. Given the similar economic features between **Takaful funds** and **Takaful windows**, the output of windows is also measured as the sum of costs. Given that **Light Takaful** (no distinction between operators and funds) is more like conventional insurance arrangements the methods described in paragraphs ~~7.204~~ to ~~7.220~~ in SNA2025 should be used to measure output.

## **D. The nature of returns on Islamic instruments in the Allocation of income account**

### **1. Background**

~~26.49~~26.50 In the context of Islamic finance, the prohibition of 'riba' (normally translated as interest) means that a provider of finance cannot impose a fixed or unconditional finance charge that is independent of the borrower's use of the funds. Sometimes, a provider of funds may expect a reward from the borrower on a

discretionary basis. For these reasons, terminology such as *profits*, *gifts* or *returns* is typically used instead of interest in Islamic accounting. However, to better integrate into the SNA/BPM, a general term describing such types of returns is required. A generic term like “similar returns” appended to interest is the option chosen. Interest and similar returns can apply to other situations of such non-conventional finance as well as to Islamic Finance.

## 2. Returns on Islamic instruments

### Interest and similar returns

~~26.50~~26.51 The broader SNA/BPM term ***Interest and similar returns*** (see paragraph xx.xx) accommodates the returns associated with Islamic finance. The concept of “similar returns” complies with Shari'ah principles and is used to describe the broader interest-alternative returns on certain Islamic debt ~~instruments~~~~liabilities~~. Retaining the term “interest” in the proposed terminology ensures continuity with the current terminology in the SNA (and BPM) to describe the investment income on conventional deposits, loans, ~~debt securities~~, and exceptionally in other accounts receivable and payable (see paragraph 25.192)~~and other liabilities~~. This approach enables the integration of Islamic financial instruments and their associated income within the existing macroeconomic statistical frameworks and eliminates the need for developing alternative classification frameworks for Islamic finance. The Islamic financial arrangements that generate investment income are discussed in Section E below. Some of these constitute equity-like instruments and generate equity-like return (e.g., dividends), but do not require introduction of new terminology.

~~26.51~~26.52 There are two key benefits to this approach. First, it preserves the universality of international statistical standards; and second, it accommodates economies with significant Islamic financial activities and incorporates the investment income for relevant Islamic financial instruments. The table below displays additional and supplementary details related to returns on Islamic instruments in SNA and BPM (please see Annex I.

Earned income account in SNA	Earned income account in BPM
D4. Property income	Investment income
D41. Interest and similar returns	Direct investment
D411 Interest	Income on equity and investment fund shares
Deposits	Dividends and withdrawals from income of quasi-corporations
Loans	Reinvested earnings
Debt securities	Interest and similar returns (D41D)
<del>Other interest bearing instruments</del>	Portfolio investment
D412 Similar returns	Income on equity and investment fund shares
Islamic deposits	Dividends on equity other than investment fund shares
Islamic loans-financings	Investment income attributable to investment fund shareholders
Islamic debt securities	Interest and similar returns (D41P)
<del>Other liability instruments subject to Islamic conventions</del>	Other investment
D42. Distributed income of corporations	Withdrawals from income of quasi-corporations
D43. Reinvested earnings on direct investment	Interest and similar returns (D41O)
D44. Investment income disbursements	

	Investment income attributable to policyholders in insurance, standardized guarantees, and pension funds
	Reserve assets
	Income on equity and investment fund shares
	Interest and similar returns (D41R)

## E. The classification of Islamic financial instruments in the accumulation accounts and balance sheet

### 1. Background

[26.52](#)[26.53](#) There are numerous types of Islamic financial arrangements that can be broadly mapped to SNA and BPM financial instruments (please also refer to Annex I). As noted above, lacking a concept of interest earnings, Islamic financial corporations often generate income through arrangements such as the financing of sales or leasing of underlying goods, sometimes including equity financing. These items can generate returns under *Interest and similar returns*, as discussed in Part D. Notably, some of these arrangements may apply to more than one SNA financial instrument depending on variations in the defining characteristics of each contract.

[26.53](#)[26.54](#) Several factors need to be considered in the instrument classifications, including:

- What form of institutional unit represented by the recipient of the finance: an equity classification for an instrument will only be possible for an entity that is a corporation;
- Whether or not the financial instrument is designed to provide a profit that has a comparatively high reliability as compared to its magnitude;
- Whether or not the financial instrument is recorded on the balance sheet of the Islamic financial institution;
- Whether or not the investment account holder has a claim on ventures or funds offered by the issuing institution (and hence the entity has institutional unit type behavior);
- Whether or not the investment account holder has a claim on the residual value of the issuing institution;
- Whether or not the lender is the supplier of the goods or services being financed, which would determine a trade credit or loan classification;
- Whether or not the financial instrument provides negotiable securities, for example in the form of participation term certificates.

The discussion below focusses on the classification of individual Islamic financial instruments in the SNA/ESS. It is clarified that the list of Islamic financial instruments discussed below and listed in Annex I is not exhaustive and the compiling agencies can use the factors in the paragraph to classify Islamic financial instruments which are not in the list.

### 2. Islamic financial instruments classified as currency and deposits (F2)

[26.54](#)[26.55](#) *Qard, Wadiah, and Amanah* deposits can be withdrawn on demand, at par, without penalty or restriction, and are generally usable for making payments by check, draft, giro order, or other direct payment facilities. These types of deposits are not linked to any profit-making ventures and are not part of the profit

and loss sharing schemes. As a result, Islamic financial institutions have the flexibility to use the funds but are required to guarantee the nominal value of the deposits. As a result, these deposits usually offer no returns or, in some cases, very small returns are offered on the basis of gifting (*Hibah*). These instruments may be classified as *Transferable deposits* (F22) or *Other deposits* (F29).

~~26.55~~26.56 **Qard-Hasan** are another form of return-free deposits, voluntarily placed by depositors to participate in the provision of funds for needy individuals or for social purposes. These may also be provided for specific purposes, as determined by the depositor. In all cases, it is interest-free and is meant to help stabilize cash flows or cater to funding needs that cannot be met using commercial arrangements. These are treated as *Other deposits* (F29).

~~26.56~~26.57 **Restricted Mudaraba** funds are funds where the investor restricts the manner as to where, how, or for what purpose the funds are invested. No mixing of funds is allowed from other sources to ensure proper management and accountability of the funds. The Islamic financial institution manages the funds either as **Mudarib** (in which the investor is engaged in risk-sharing), or as **Wakil** (i.e., provision of intermediation services for a fixed fee with no participation in the investment results). Only **Restricted Mudaraba** held on-balance sheet should be classified as *Other deposits* (F29).

~~26.57~~26.58 **Unrestricted Mudaraba** funds are funds where the investor fully authorizes an Islamic financial institution to invest the funds without restrictions as to where, how, or for what purpose the funds should be invested, as long as it is deemed appropriate. The mixing of funds from other sources (including shareholders' funds) is permitted and separate disclosure in the financial statement is therefore required. **Unrestricted Mudaraba** can be divided into three distinct types, two of which are discussed below, while a third type is discussed below under *Shares*.

- **Mudaraba not fixed deposits** are accepted without time frame (not fixed), hence the investors are free to withdraw their money at any time. This type of unrestricted accounts can be considered analogous to saving deposits at a conventional financial institution and should be classified under *Other deposits* (F29).
- **Mudaraba fixed deposits** are accepted for a fixed period that provides an opportunity for Islamic financial institutions to invest in more profitable long-term projects. This type of unrestricted account can be considered as analogous to a time deposit at a conventional financial institution and will usually generate higher returns than for non-fixed period deposits. These are also classified as *Other deposits* (F29).

~~26.58~~26.59 In the case of **Wakalah deposits**, the bank acts as an agent for investment of depositor's funds in exchange for a fee, usually in the 1.5 to 2 per cent range. Depositors are offered an indicative or nominal return. If the actual return is lower, the depositor only receives this latter return; if the actual return is higher, the bank only pays the indicative return and keeps any excess as an "incentive fee". Because of the possibility of the bank earning this incentive, it will often not charge a fee. These instruments can be classified as *Transferable deposits* (F22) or *Other deposits* (F29).

~~26.59~~26.60 **Profit and loss sharing certificates** are investors' deposits that resemble shares but do not provide a claim on the residual value of the Islamic financial institution and participation in its governance. The certificates should be classified as *Other deposits* (F29) if non-negotiable.

### 3. Islamic financial instruments classified as debt securities (F3)

~~26.60~~26.61 **Mudaraba, fixed with mudaraba certificates** are arrangements accepted for a fixed term, by way of negotiable instruments (called investment deposit certificates or Mudaraba certificates). This type of unrestricted investment has characteristics similar to those of conventional market securities and is typically classified as a *debt security*, if not part the own funds of the financial institution. A separate disclosure of off-balance sheet positions is required to be kept by the Islamic financial institution.

~~26.61~~26.62 **Sukuk** are investment certificates issued by Islamic financial institutions to obtain funding. **Sukuk** (plural of *Sakk*), are certificates (commonly known as Islamic bonds), with each representing a proportional undivided ownership right in tangible assets, monetary assets, right to use others' assets (*Usufruct*), services, debts, a pool of predominantly tangible assets, or a business venture (such as *Mudaraba* or *Musharaka*).

These assets, which must be clearly identifiable, may be in a specific project or investment activity in accordance with Shari'ah rules and principles. **Sukuk** might often be thought of as providing a securitization wrapper around an underlying contractual arrangement. If they involve an intermediate legal structure such as a special purpose entity (SPE), then consideration of whether the SPE should be recognized as an institutional unit may be required, depending on the legal and other specific circumstances. The following three types of sukuk contracts are the most prominent: (i) *Sukuk Ijarah*; (ii) *Sukuk Musharaka*; and (iii) *Sukuk Murabaha*, which are all negotiable instruments, although the last type of arrangement only becomes negotiable when certain conditions are met. Different types of *Sukuk* will have fixed income properties, equity-like properties, or more complex types of arrangements for the returns.

- **Fixed Income Sukuk** are instruments which are normally either sale or lease based. Sale based contracts represent a debt, and therefore may not be bought/sold in the secondary market at other than par value. Lease based contracts such as *Ijarah* do not have secondary market restrictions as the revenue streams are based on a tangible underlying asset. *Ijarah Sukuk* also typically have a redemption payment, representing the return of beneficiary's share in the underlying tangible asset back to the issuer. Examples include: *Murabaha* (sale at mark-up); *Salam* (forward commodity sale); *Istisna'a* (manufacturing sale); and *Ijarah* (lease based).
- **Variable profile Sukuk or Wakalah Sukuk** represent an agency arrangement in which the *Sukuk* holder delegates responsibility to the issuer to carry out Shari'ah compliant revenue generating activity. The precise nature of this activity can vary, and it can encapsulate other transaction types within it (e.g., *Ijarah*, *Murabaha*, etc.). The aggregate return on the activity may be either fixed or variable, depending on the agreement between the counterparties.
- **Hybrid Sukuk** may vary in form at different points in their life cycle. For example, *Istisna'a* plus *Ijarah Sukuk* may be used by an issuer to raise funds to first construct an asset before leasing it out.

[26.62](#)[26.63](#) **Profit and loss sharing certificates** are investors' funds that resemble shares but do not provide a claim on the residual value of the Islamic financial institution and participation in its governance. The certificates should be classified as *Debt securities* if they are negotiable.

[26.63](#)[26.64](#) **Participation term certificates** are long-term investment instruments that entitle the holder to a share of an Islamic financial institution's profit. These certificates should be classified as *Debt securities* if the certificates concern debt liabilities of the institution.

#### 4. Islamic financial instruments classified as Loans (F4)

[26.64](#)[26.65](#) **Qard-Hasan financing** is a return-free financing that is made to needy individuals or for some social purpose. This financing is usually extended on a goodwill basis, and the debtor is required to repay only the principal amount of the financing. The debtor may, however, at his or her discretion, pay an extra amount beyond the principal of the financing (without promising it) as a token of appreciation to the creditor.

[26.65](#)[26.66](#) In a **Murabaha financing** contract, an Islamic financial institution purchases goods upon the request of a client, who usually makes deferred payments to the financial institution that cover costs and an agreed upon return. These contracts resemble collateralized loans within conventional finance, in which the underlying goods, such as properties or automobiles, are registered under the customer's name and are used as collateral. The disclosure of the cost of the underlying goods is required. The financial institution handles payment to the supplier including direct expenses incurred (delivery, insurance, storage, fees for letter of credit, etc.). Operating expenses of the financial institution are not included. This arrangement can be defined as a sale of goods at cost plus profit margin.

[26.66](#)[26.67](#) **Tawarruq financing (commodity Murabaha)** is a financial instrument in which a buyer purchases a commodity from an Islamic financial institution on a deferred payment basis, and the buyer sells the same commodity to a third party on a spot payment basis. This is an extension of *Murabaha* whereby the financial institution arranges for the sale of the item. The buyer basically borrows the cash needed to make the initial purchase. Later, when cash is secured from the second transaction, the buyer pays the original seller the instalment or lump sum payment he owes (which is cost plus markup).

26.6726.68 **Mudaraba financing** constitutes a partnership between an Islamic financial institution and a client in which the institution provides capital (*Rab al-Mal*) and the client provides skillful labor. This financing is a type of partnership whereby skill and money are brought together to conduct business. Profits generated from the business are shared according to the agreement, while losses are borne fully by the capital provider, except when losses are due to misconduct, negligence, or violation of the agreed conditions by the client. Although this arrangement has features of equity, it has a fixed-term nature and therefore represents a fixed-term claim on the client rather than a claim on any residual value.

26.6826.69 **Musharaka** represents a partnership between an Islamic financial institution and an enterprise in which both parties contribute to the capital (*Rab al-Mal*) of partnership. The financial institution and client agree to share any profits generated from the venture according to the pre-agreed ratio, with any losses shared according to the ratio of contribution. This type of financing can be structured as a *loan* where the financial institution provides financing in the form of working capital to an entity but does not have a claim on the residual value of the debtor enterprise.

26.6926.70 **Mushtarakah** is a combination of both **Musharaka** and **Mudaraba**. It can be treated as *loans* if there is no residual claim on the value of the debtor entity.

26.7026.71 **Bai Muajjal** is a type of financing provided by an Islamic financial institution to its client by supplying desired commodities or services with deferred payments. This contract is classified as *loans* if the supplied commodities or services are from third parties.

26.7126.72 **Bai Salam** is a short-term financing agreement in which an Islamic financial institution makes full prepayments (spot payment) for future (deferred) delivery of a specified quantity of goods on a specified date. The financial institution and a supplier may engage in such a contract, in which the supplier agrees to sell their product prior to the goods being delivered. Generally, the agreed spot price is less than the future price of the goods, which ensures a return to the financial institution. This arrangement should be classified as *loans*, only if the goods or services produced are not for the financial institution's own use.

26.7226.73 **Istisna'a financing** is a partnership between an Islamic financial institution and an enterprise, usually manufacturer or construction company, whereby the financial institution places an order and provides financing to the enterprise to manufacture/construct and or supply certain goods or buildings. Upon or before the delivery of the order, the financial institution usually enters into a contract with another party (the ultimate purchaser) at a price higher than the original contract of the **Istisna'a**, thus generating profits. These arrangements are classified as *Loans*, if the produced goods or constructed buildings are for the use of the ultimate purchaser. **Ju'alah** is an **Istisna'a** contract applicable for services as opposed to a manufactured good. It may be a *Loan* if the services are not for the financial institution.

26.7326.74 **Bai bil wafa or Bai bil-istighlal** are sales (ba'i) in which the seller has the right, as stipulated in the contract, to repurchase the underlying property (real estate) from the buyer by refunding the purchase price. The right of redemption is given to the original seller upon an understanding that the buyer will give (i.e., resell) the property back to the seller and receive the original price. The buyer agrees to honor that understanding and hence the name *Wafa* which means to honor.

26.7426.75 An **Ijarah** is a contract in which an Islamic financial institution purchases capital equipment or property and leases it to an enterprise. The financial institution may either rent out the equipment (**simple Ijarah**) or receive a share of the profits earned through its use. There are two types of **more sophisticated Ijarah**.

- **Ijarah Muntahia Bittamleek (Ijarah MBT)** is a hybrid instrument and can be arranged as a pure operating lease or as a lease-to-own arrangement.

- In the case of the pure operating lease version of **Ijarah MBT**, the title for the underlying asset is not transferred to the client (lessee), and ownership risks of the assets are borne by the Islamic financial institution (usually through a separate unit that it owns). Operating *ijarah* should be treated in the same way as a conventional operating lease (rental agreement for some non-significant portion of the asset's economic life) and does not give rise to a financial instrument. It is discussed only to distinguish it from *ijarah MBT* and **Ijarah Wafa-Iktina** below.

- In the case of the **Ijarah MBT** lease to own arrangement (or financing *Ijarah*), the title for the underlying asset may be transferred to the lessee over the term of the lease or at the end of the lease arrangement. This makes it resemble a conventional financial lease in some ways, however

the risks and rewards incidental to ownership remain with the lessor throughout the lease term until the asset is transferred to the lessee. to this end, there can be both a lease contract and a transfer of ownership contract involved. This arrangement generally constitutes a long-term lease, and the lessee could be considered the economic owner (but not the legal owner) for purposes of the economic accounts. This form of Ijarah should be classified as *Loans* over the period of the lease

- ***Ijarah Wa-iktina***- is the financing of an acquisition of an underlying asset under a lease-to-purchase arrangement, and it (~~financial lease~~) involves two stages. The first stage is the lease of underlying asset over the lease period, which covers the majority of the asset's economic life, and for which the lessee is effectively considered the economic owner (but not the legal owner) in the economic accounts. The second stage is the transfer of ownership of the residual value of the asset at the end of the lease period. This arrangement (~~Financing ijarah~~), which is similar to resembles a conventional financial lease, should be classified as *Loans* over the period of the lease.

## 5. Islamic financial instruments classified as equity and investment fund shares (F5)

<sup>26.75</sup><sub>26.76</sub> As noted above, a ***Mudaraba contract*** is a partnership of the Islamic financial institution and the client. ***Restricted Mudaraba*** that are held off-balance sheet should be classified as *Shares* (equity) if considered part of the own funds of the financial institution. A separate disclosure of off-balance sheet positions is required to be kept by the Islamic financial institution. ***Mudaraba fixed with Mudaraba certificates*** constitutes ***unrestricted Mudaraba*** arranged through negotiable instruments with characteristics similar to those of conventional market securities, and it is classified as *Shares* if considered part of the own funds.

<sup>26.76</sup><sub>26.77</sub> ***Participation term certificates*** are long-term investment instruments that entitle the holder to a share of a corporation's profit. These certificates are treated as *Shares* if considered as part of the own funds.

<sup>26.77</sup><sub>26.78</sub> As noted above, ***Sukuk instruments*** constitute investment certificates issued by Islamic financial institutions to obtain funding. These should be classified as *Shares*, only in the instance where the owner of the security has a claim on the residual value of the issuing entity. ***Equity-like sukuk*** are instruments normally based on some sort of partnership arrangement, with the risk/ reward sharing ratio agreed ex ante. In these contracts, it is impermissible for one party to provide a guaranteed fixed payment (either in terms of periodic return or maturity payment) to the other. ***Mudaraba sukuk*** can resemble ***Wakalah*** in terms of cashflows, but the contractual relationship between parties will differ. Examples of these arrangements include: ***Musharaka*** (pure partnership), and ***Mudaraba*** (silent partnership or '*Commenda*').

<sup>26.78</sup><sub>26.79</sub> ***Musharaka*** constitutes a partnership between an Islamic financial institution and an enterprise in which both parties contribute to the capital (*Rab al-mal*) of partnership. In this type of arrangement, the financial institution and client agree to share any profits generated from the venture according to the pre-agreed ratio; a loss is shared according to the ratio of contribution. This type of financing is classified as *Shares* when the financial institution acquires a claim on the residual value of the enterprise.

<sup>26.79</sup><sub>26.80</sub> ***Mushtarakah*** is a combination of both ***Musharaka*** and ***Mudaraba***. It can be treated as *Shares* if there is a residual claim on the value of the debtor entity.

## 6. Islamic financial arrangements identified as insurance related financial instruments (F6)

<sup>26.80</sup><sub>26.81</sub> The ***Mudaraba Takaful model*** is based on the Islamic financial instrument known as ***Mudaraba*** that relies on profit sharing principle. In this model, the Takaful operator is the entrepreneur (*Mudarib*) providing management skills or labour. The operator is appointed by the participants, who act as investors or fund contributors (*Rab al-mal*). Any surplus or profit resulting from takaful fund investments are shared between the takaful operator and takaful fund according to a pre-agreed ratio, while the possible losses are borne only by the takaful fund unless there is element of negligence from the takaful operator.

[26.81](#)[26.82](#) The **Wakalah Takaful model** is based on the Islamic financial instrument known as **Wakalah** – a contract between the takaful participants and the **Takaful operator** that acts as an agent (*Wakil*). Any surplus realized from the investment of the participants' funds will go to the participants only, as the takaful operator is entitled to an agency fee for the services rendered on mutual agreement and the predetermined terms in the contract. The profit and the losses derived from the operations of **Takaful fund** and the investments belong to takaful fund only.

[26.82](#)[26.83](#) **Hybrid Takaful** is an Islamic insurance contract that is structured to combine more than one financial instrument.

- The **Wakalah-Mudaraba** model combines the features of two models. According to this hybrid model, the participants and the **Takaful operator** sign two contracts: As per the **Wakalah** contract, the operator is entitled to a fee from the contributions paid by the participants; and as per the **Mudaraba** contract the operator is entitled to the predetermined share of profit gained from the investments of the takaful fund.
- Another hybrid model is **Waqf-Wakalah-Mudaraba** that integrates elements of the charitable endowment **Waqf** in the above arrangement, where no party gets the underwriting surplus so that the original contributions remain in the common pool for the purpose of reinvestment and to enhance sustainability.

## 7. Islamic financial instruments classified as financial derivatives (F7)

[26.83](#)[26.84](#) Financial derivatives have a prominent role in conventional finance, but less so in Islamic finance. The prohibition of gambling and excessive uncertainty/risk as well as short sales or financing activities, significantly limit the use of derivative contracts in this environment. Moreover, although certain types of forward sales are permitted, these are not necessarily considered derivative contracts.

[26.84](#)[26.85](#) That said, derivative contracts whose sole purpose is hedging (that is, to minimize any risk exposures) do not seem to be incompatible with Shari'ah principles. Therefore, Islamic financial institutions may enter into derivative contracts purely for hedging purposes (regardless of what the counterparty's objective might be), and this is the case in some countries. However, the use of financial derivative types, remains a somewhat open-ended issue in Islamic finance in terms of a general treatment that can apply across economies. As a result, their use varies across jurisdictions, depending upon the domestic Shari'ah regulators and legislation.

## 8. Islamic financial instruments classified as other accounts payable/receivable (F8)

[26.85](#)[26.86](#) **Istijrar** refers to an agreement where the buyer purchases commodities under a single agreement from a supplier from time to time in different quantities. The deal is considered as a sole agreement when all terms and conditions are finalized.

[26.86](#)[26.87](#) **Istisna'a financing** relates to goods or buildings for the Islamic financial institution's own use and should be classified as trade credit and advances. A **Ju'alah** contract is essentially an **Istisna'a** that applies to services as opposed to a manufactured good.

[26.87](#)[26.88](#) **Bai Muajjal financing** (discussed in paragraph 26.70) is classified as trade credit if it is a direct extension of credit by the supplier.

[26.88](#)[26.89](#) If the associated goods or services in **Bai Salam financing** (discussed in paragraph 26.71) are for use by the Islamic financial institution (lender), the arrangement would be considered trade credit.

## 9. Islamic financial instruments and related investment income under the functional classification of BPM7

[26.89](#)[26.90](#) This section follows the classification of Islamic instruments discussed above but extends it to account for the functional classification used in the external sector statistics. The classification of equity and debt security like instruments to functional categories follows the principles from Chapter 6, *BPM7*.

~~26.90~~26.91 *Qard, Wadiah, and Amanah deposits* are included in the broad category **other investment** under currency and deposits, specifically, *Transferable or other deposits* (F22 or F29). Related income would be reflected under investment income, again under other investment as *Interest and similar returns*. A similar treatment is to be applied for *Quard-Hassan deposits*, under *Other deposits*, although in this case investment income is not relevant.

~~26.91~~26.92 *Restricted Mudaraba funds* are included in the broad category **other investment** under currency and deposits, specifically, *Other deposits, or as portfolio investment Equity*, depending on whether the funds are held on-balance sheet or off balance sheet. *Unrestricted Mudaraba* funds are classified under *Other deposits* for both for both fixed term and non-fixed term arrangements. However, fixed arrangements with *Mudaraba certificates*, should be classified as either *debt* (F3) or *equity* (F5) under **portfolio investment**, while the corresponding investment income is to be recorded as *Interest and similar returns* or *Dividends*. *Participation term certificates* follow the exact same treatment as fixed mudaraba with certificates. *Profit and loss sharing certificates* are included as *Other deposits* (F29) under other investment if not negotiable or *Debt securities* (F3) under portfolio investment if negotiable, with income as *Interest and similar returns* recorded under other investment or portfolio investment.

~~26.92~~26.93 *Sukuk* can take the form of a debt security (F3) or an equity security (F5) under portfolio investment with investment income recorded as interest and similar returns or dividends. *Fixed – income sukuk* constitutes a *Debt security under portfolio investment*. *Equity-like sukuk* is to be recorded, as the name suggests, under **portfolio investment equity security**. *Variable profile sukuk* can be treated as debt or equity security under portfolio investment, depending on the precise nature of the arrangement. Correspondingly, income on the above instruments can be under **portfolio investment** as *Interest and similar returns* (from securities) or *dividends* (from equity securities).

~~26.93~~26.94 *Quard-hasan financing* is to be classified under **other investment** as a loan (F4). *Murahaba financing* also constitutes *Loans*. *Mudaraba financing, tawarruq* (commodity murabaha) as well as *bai bil wafa* and *bai bil istighlal* are all treated as *loans* (F4) in **other investment**. *Bai Muajjal, Bai Salam, Ju'ala, and Istisna'a financing* is to be classified as either *loans* or *trade credits and advances*, the latter only when the commodities are used by an Islamic financial institution. In cases where an optional or required return is paid on these instruments, the investment income is classified as **other investment** as *Interest and similar returns*.

~~26.94~~26.95 *Ijarah Wa-iktina* (akin to a financial lease) or *Ijarah MBT* (financing ijarah) ~~(financial lease)~~ is classified as *Loans* under other investment and the investment income is recorded under **other investment** *Interest and similar returns*. It should be noted that *simple Ijarah or Ijarah Muntahia MBT Bittamleek or in the case of* operating ijarah (operating lease) ~~does~~ not give rise to entries in the financial account. Rather, ~~these# areis~~ treated as *Operating leasing services* in the services account.

~~26.95~~26.96 *Musharaka* and *Mushtarakah* are classified as either *loans* (F4) or *equity* (F5), with the corresponding income flows to be recorded as *Interest and similar returns* or *Dividends*.

## F. Economic ownership of non-financial assets under Islamic financial arrangements

### 1. Special considerations in Islamic Finance and the regulatory framework

~~26.96~~26.97 The SNA and BPM make a clear distinction between legal ownership and economic ownership. The legal owner of assets or products is the institutional unit entitled by law to claim benefits associated with those items. The legal owner may transfer (through a contract) the risks and rewards related to the use of the relevant assets to another economic agent. This other agent then becomes the economic owner and is the institutional unit entitled to claim the benefits, or rewards, associated with the use of the assets over the course of an economic activity by virtue of accepting the economic risks over the relevant period. Usually, the legal owner coincides with the economic owner but, when this is not the case, the relevant assets are allocated to the sector of the economic owner. This distinction is also relevant for Islamic finance in national accounting and external sector statistics, though Islamic accounting standards may suggest otherwise.

~~26.97~~26.98 Islamic finance accounting standards recommend recording the ownership of the underlying non-financial assets in the balance sheets of the Islamic financial institutions (or institutional units who may be lessors). This is the case, even though they may not actually use the assets in their productive activities, or they may hold them only briefly. In other words, the focus in the accounting standards is on legal ownership. Consequently, one interpretation of the financial statements of Islamic financial institutions suggests that they are comparatively more involved in (and more exposed to) non-financial activities than is perhaps the case. Of course, this interpretation also ignores the issue of economic ownership.

~~26.98~~26.99 Another interpretation, arguably more consistent with shared relationships in principles of Islamic finance as well as the related guidance for conventional finance, is that the economic ownership rests with the users of the assets. Therefore, the user of the non-financial asset can be determined to be the economic owner in most cases. Thus, there is a need to account (in a macroeconomic statistical sense) for the role of Islamic financial institutions and instruments under these arrangements as well as the nature of their economic activities under certain arrangements. This provides a means to determine the economic ownership, or changes in economic ownership, of the relevant assets.

~~26.99~~26.100 With respect to the treatment of economic ownership in financing arrangements, it is useful to consider the following two complicating points. First, Islamic financial institutions (banks in particular) undertake various economic activities and may set up separate entities to facilitate these activities, either consolidated in their financial statements or unconsolidated (as separate wholly owned institutional units). Therefore, in some of these arrangements, it is possible that Islamic financial institutions have established a separate institutional units (which could be non-financial entities), ~~(often,~~ in partnership with other ~~entities~~units,) which will then be the legal and economic owner of the underlying assets. One example is real estate investment whereby Islamic financial institutions can co-invest in a venture with other units (say, a construction firm) to develop properties which the financial institution's subsidiary temporarily owns (at least until they are sold to the final user). If so, this does not change the arrangement materially. Second, regardless of whether a separate institutional unit is set up, Islamic financial institutions can sometimes act as facilitators by transferring the economic ownership of the items from the seller to the client (the participant with the need to make use of these assets) which would take on financial risk in the process. This possibility does change the arrangement and does allocate economic ownership at the outset. In both cases, not recording the economic ownership of the underlying assets in the balance sheets of Islamic financial institutions (or their wholly owned subsidiaries) helps to better articulate their role as providers of financial services that facilitate the transfer of non-financial assets or products. Besides, the often-brief ownership of such items by Islamic financial institutions could be considered as a form of constructive possession (*Qabd Hukmi*) or physical possession (*Qabd Fe'eli*) and should not be considered as economic ownership.

## 2. Economic ownership under different types of Islamic financial arrangements

### Background

~~26.100~~26.101 This section focuses on the ownership of non-financial assets related to sales, leasing, pure lending and equity financing and its treatment in Islamic finance accounting frameworks. It also touches on other similar Islamic financing arrangements which are typically based on trading models or profit and loss sharing models involving underlying non-financial assets or products. This section invariably relies heavily on the above discussion of financial instruments in Section E.

~~26.101~~26.102 The ultimate purchasers of the underlying non-financial assets are considered as the economic owner of the assets obtained through Islamic financial institutions' arrangements. The economic owners claim the benefits and assume the risks associated with their use. The time of the acquisition of the underlying items is assumed to be the time at which the economic ownership changes hands. When a change of ownership is not obvious, the time at which the assets enter into the books of the transaction partners may be a good indication and, failing that, the moment when physical possession and control is acquired.

### Economic ownership structures

~~26.102~~26.103 A convenient way to group transactions and positions in Islamic financing instruments is an

aggregation by term as well as by characteristics and purpose. From that perspective, economic ownership for the different arrangements can be better assessed. The discussion below is not deemed to be exhaustive but provides a general assessment on the issue of economic ownership.

### *Shorter-term financing*

~~26.103~~26.104 Where the financial institution acquires goods or services for its own use, then it is the economic and legal owner of these products. However, it is more relevant to focus on shorter-term financing related to sales of goods and services where the purchaser/user is the owner, or at least the economic owner, early in the arrangement. In these cases, the Islamic financial institution has only a financial claim on the borrower, especially where the products are of relatively low value. Different treatment may apply, depending on the characteristics of the financial arrangement.

~~26.104~~26.105 Sometimes, the financial institution takes legal ownership of products for a very short period (e.g., *Murabaha*), before selling it. However, the intent of most of these financial arrangements usually is the facilitation of a purchase by the client and ultimate user. When the products are sold, the final user is the legal and economic owner, while the financial institution will have a claim on the client for the amount financed.

~~26.105~~26.106 In other arrangements, the Islamic financial institution holds the products for a period of time. Take the example of a spot purchase of goods for a future sale, sometimes at a higher price (e.g., *Bai Salam*). While the financial institution may become the legal and economic owner for that period only, for economic accounting purposes, the purchasers/users are considered the economic owners (in the case of a loan) of the products since they ultimately claim the benefits and assume the risks associated with their use (see paragraph 26.71). When the goods are subsequently acquired by the users, then they will become the legal and economic owners. Another example is with a Bai bil Wafa / Bai bil-Istigal contract with the financial institution purchaser pledges to sell it back to the client at a fixed future date, which makes the purchaser the legal and economic owner for a (typically short) period of time.

~~26.106~~26.107 A last arrangement to consider is an operating lease (*simple Ijarah*) which is a rental agreement for a period that does not cover a significant portion of the non-financial asset's economic life (see paragraph 26.73). The lessee must return the item at the end of the lease term and does not have an option to purchase. The lessor, in this case the Islamic financial institution, is both the legal and economic owner of the asset (usually through a separate unit that it owns), as it assumes the risks and rewards related to the ownership of the asset.

### *Longer-term financing*

~~26.107~~26.108 Substantive issues with respect to economic ownership of a financed non-financial asset arise in the case of the acquisition of relatively high value goods, construction, or project finance over an extended period of time. That financing can be in the form of *Loans*, such as with *Istisna'a*. One can distinguish a period of time where the Islamic financial institution makes progress payments to the contractor. In this period, the financial institution is the legal and economic owner of the asset. However, for economic accounting purposes, the customers who request the construction or manufacturing of the said non-financial asset are considered the economic owners of the products since they ultimately claim the benefits and assume the risks associated with their use. Nevertheless, Once the asset is complete, economic ownership shifts to the actual user, though the financial institution holds a claim on the asset until the debt is extinguished.

~~26.108~~26.109 Other types of longer-term financing arrangement are *Mudaraba financing*– and *Musharaka* partnerships. In both instances the Islamic financial institution only provides funding, though it may share in the profits (*Musharaka*). Any underlying non-financial assets are economically owned by the party that uses those assets, even though the financial institution can remain the legal owner for the duration of the financing agreement.

~~26.109~~26.110 Financial leases (*Ijara Wa-iktina*) constitute another form of longer-term financing where economic ownership is clear. In this case, while the lessor is the legal owner of the asset, the risks and rewards related to the ownership of the asset are transferred to the lessee over the term of the *Loan* lease. Further, tThe lease

term typically covers a substantive portion of the economic life of the assets, and the lessee has the option of purchase at the end of the lease period. The instrument is treated as a loan. The lessee is, for economic accounting purposes therefore, is considered the economic owner. The financial lease also provides a return for the lessor, i.e., the Islamic financial institution, to compensate it for providing the financial means to acquire the asset. The lessor is also entitled to the residual value of the leased asset at the end of the lease term, either as payment for the purchase of the depreciated asset by the lessee, or by getting economic ownership of the depreciated asset.

### 3. Economic ownership of non-financial assets in the case of a client's default

~~26.110~~26.111 For items acquired for use by a financing contract, defaulting on the corresponding payments is an issue that may arise in Islamic finance. Given Shari'ah principles' social benefit aspects incorporated in Islamic finance, it stands to reason that, in several cases, economic ownership is unaffected when the economic owners of non-financial assets default on their payments in financing arrangements such as *Murabaha* and *Istisn'a*. It can be argued that the default only relates to the financial payment, not to the full arrangement itself. Any contract with profit sharing or participation cannot be considered in full default, so the user would remain the economic owner. Therefore, it can be assumed that defaulting clients will remain the economic owners, but there are likely some non-mutually exclusive and complicating considerations.

~~26.111~~26.112 It is possible, however, that default actually leads to a change in economic ownership. If, for example, the Islamic financial institution determines that the borrower did not enter into a contract in good faith, then the institution (subject to the clauses of the contract) could repossess the assets and temporarily becomes the economic owner as well as the legal owner, while the borrower could face a penalty. Also, in the case of a shortage of a particular asset (e.g., dwellings), or in the case of neglect of the maintenance of the asset, the financial institution may be able to find a more worthy or needy client. A further consideration might relate to the nature of the default. For example, it could be the case that circumstances indicate that the non-performing loan is a write-off, and the borrower is not expected to ever be able to repay. In this case, a change of economic ownership may be warranted. In other words, it may all depend on the details of the situation, in addition to the type of financing and the actual use of the commodity (e.g., a community building versus a business asset).

~~26.112~~26.113 Lastly, and more specifically, for financial leases or *Ijara Wa-Iktina* the situation might be clearer. It is likely that in some or many of these instances the lessor will seek to find another lessee.

## ANNEX: Classification of Islamic financial instruments and income

Instrument	National Accounts	External Sector Statistics
Qard, Wadiah, and Amanah	FA: Transferable deposits (F22) or Other deposits (F29)  Income: Interest and similar returns (D41)	FA/IIP: Other investment: Currency and deposits: Transferable deposits or other deposits  Income: Primary income: Investment income: Other investment: Interest and similar returns
Qard-hasan	FA: Other deposits (F29)  Income: Interest and similar returns (D41)	FA/IIP: Other investment: Currency and deposits: Other deposits  Income: N/A
Restricted Mudaraba funds	FA: Other deposits (F29) or Equity (F51)  Income: Interest and similar returns (D41) or dividends (D421)	FA/IIP: Other investment: Currency and deposits: Other deposits or Portfolio investment: Equity Income: Primary income: Investment income: Other investment: Interest and similar returns (D41O) or Portfolio investment: Dividends
Mudaraba – fixed	FA: Other deposits (F29)	FA/IIP: Other investment: Currency and deposits: Other deposits
Mudaraba - not fixed	Income: Interest and similar returns (D41)	Income: Primary income: Investment income: Other investment: Interest and similar returns
Mudaraba – fixed with mudaraba certificates	FA: Debt security (F3) or Equity security (F5)  Income: Interest and similar returns (D41) or dividends (D421)	FA/IIP: Portfolio investment – Debt or Equity security  Income: Primary income: Portfolio investment: Debt or equity securities: Interest and similar returns (D41O) or dividends (D42P)
Participation term certificates	FA: Debt security (F3) or Equity security (F5)	FA/IIP: Portfolio investment – Debt or Equity security
Sukuk (generally)	Income: Interest and similar returns (D41) or dividends (D421)	Income: Primary income: Portfolio investment: Debt or equity securities: Interest and similar returns (D41P) or dividends (D42P)
Sukuk (Variable profile)		
Sukuk (Equity-like)	FA: Equity security (F5)  Income: Dividends (D421)	FA/IIP: Portfolio investment – Equity security Income: Primary income: Portfolio investment: Equity securities: Dividends (D42P)
Sukuk (fixed-income)	FA: Debt security (F3)  Income: Interest and similar returns (D41)	FA/IIP: Portfolio investment – Debt security  Income: Primary income: Portfolio investment: Interest and similar returns
Wakalah deposits	FA: Transferable deposits (F22) or Other deposits (F29)	FA/IIP: Other investment: Currency and deposits: Transferable deposits or other deposits

Instrument	National Accounts	External Sector Statistics
	Income: Interest and similar returns (D41)	Income: Primary income: Investment income: Other investment: Interest and similar returns (D41O)
Murabaha financing Qard-hasan	FA: Loans (F4)  Income: Interest and similar returns (D41)	FA/IIP: Other investment: Loans Income: Primary income: Investment income: Other investment: Interest and similar returns (D41O)
Istisna'a financing Bai Salam Bai Muajjal	FA: Loan (F4) or Trade credits and advances (F81)  Income: Interest and similar returns (D41)	FA/IIP: Other investment: Loans Or Other investment: Trade credit and advances Income: Primary income: Investment income: Other investment: Interest and similar returns
Ijarah	Operating Ijarah: Production account: market output (P11) Financing Ijarah FA – Loans (F4)  Income – Interest and similar returns (D41)	Operating Ijarah CA: Trade in Services: Other business services Financing Ijarah FA/IIP: Other investment: Loans  Income: Primary income: Investment income: Other investment: Interest and similar returns (D41O)
Musharaka	FA: Loan (F4) or equity (F5)  Income: Interest and similar returns (D41) or dividends (D421)	FA/IIP: Other investment – Loans Or Portfolio investment – Equity security Income: Primary income: Investment income: Other investment: Interest and similar returns (D41O) Or Income: Primary income: Portfolio investment: Equity securities: Dividends (D42P)
Mudaraba Financing Tawarruq  Bai bil Wafa  Bai bil-Istighlal	FA: Loan (F4)  Income: Interest and similar returns	FA/IIP: Other investment – Loans  Income: Primary income: Investment income: Other investment: Interest and similar returns
Ju'alah	FA: Loan (F4) or Trade credits and advances (F81)  Income: Interest and similar returns (D41)	FA/IIP: Other investment: Loans Or Other investment: Trade credit and advances Income: Primary income: Investment income: Other investment: Interest and similar returns
Mushtarakah	FA: Loan (F4) or equity (F5)  Income: Interest and similar returns (D41) or dividends (D421)	FA/IIP: Other investment – Loans Or Portfolio investment – Equity security  Income: Primary income: Investment income: Other investment: Interest and similar returns Or Income: Primary income: Portfolio investment: Equity securities: Dividends
Istijrar	FA: Trade credits and advances (F81) Income: Interest and similar returns (D41)	FA/IIP: Other investment – Trade credit and advances  Income: Primary income: Investment income: Other investment: Interest and similar returns (D41O)

## **Chapter 27: Contracts, leases, licenses and permits (Part 5 of chapter 17 in the 2008 SNA, moved downwards)**

### **(OLD Chapter 17 Part 5: Contracts, leases and licences)**

#### **I.A. Introduction**

~~17.2~~27.1 Many transactions that take place in the economy and are recorded in the SNA are specified in terms of a contract between two institutional units. The majority of contracts are such that one unit provides a good, service or asset to the other unit for an agreed payment at an agreed time (possibly immediately after agreeing on the price). Such contracts may be written and legally binding or may be informal or even only implicit. If a unit accepts the estimate provided by a builder for the cost of specified work, the contract is written and may well be legally binding. If a book is ordered from a bookshop but there is a delay in delivery, there is an informal contract between the book shop and the customer but it is unlikely to be enforceable by either side. Whenever a customer asks how much a given service will cost, whether it is a haircut, the delivery of a heavy product or entry to a cinema, accepting the service at the quoted price is in effect an implicit contract. However, all these contracts are simply agreements about the terms under which goods, services and assets are provided to the customer along with the legal ownership of the item. The only extent to which these contracts feature in the SNA is that they determine the pointtime at which the transaction is to be recorded in the accounts. This is the time at which the ownership of the good, service or asset changes. For services, this is always when the service is delivered and for goods it may coincide with the time of delivery. However, the time of recording is never determined by the time when payment is made. Any difference between the time of payment and time of change of ownership gives rise to an entryentries in the financial account under other accounts receivable ~~orand~~ payable.

~~17.2~~27.2 ~~However, there are other~~In addition to these informal and implicit contracts that underpin most transactions, there are also formal contracts and legal agreements variously described as leases and licences (or permits) where the terms of the agreement may affect the time of recording of transactions made under the agreement as well as the classification of payments and the ownership of the item subject to the agreement. The purpose of this ~~part of the~~ chapter is to provide guidance on how transactions made under these more complex arrangements are to be recorded in the SNA.

~~27.1~~ — ~~The first item for discussion concerns the different sorts of leases recognized in the SNA. The next topic for discussion is the treatment of permits to use natural resources. This is of particular importance when it is government that claims ownership of the resource on behalf of the community at large but can apply to privately owned resources also. This leads naturally into a discussion of the treatment of assets where more than one unit has a claim to ownership, or the benefits of ownership accrue to more than one unit.~~

~~27.2~~ —

~~27.3~~ — ~~Some contracts are not connected with the use of assets. The first contracts for discussion are licences (or permits) given to undertake particular activities independently of any assets that may be used in the activity. Here there are different treatments when the permits are issued by government and when they are given by other institutional units. The next point for consideration is when a contract can constitute an asset in itself, independently of the subject of the contract. Finally, a number of clarifications are made concerning the timing and nature of payments made under a contract.~~

~~27.4~~ —

~~27.5~~ —

~~27.3~~ — Section B considers the treatment and recording of operating and financial leases. Section C discusses the recording of rights to use natural resources and the different arrangements and considerations that are relevant. General considerations are presented first followed by a discussion of the treatments for different natural resources. Section D describes situations where assets can be considered to be shared including an explanation and example of the split-asset approach to recording natural resources. Section E discusses the relevant recording treatments for a range of other situations in which permission is granted to undertake specific activities, including the treatment of permits to use the environment as a sink. Sections F, G and H

cover off on a number of smaller topics namely contracts for future production, the situations in which leases can be considered assets and the treatment of time-share arrangements and lost deposits.

27.6

## **J.B. Leases**

~~17.5~~27.4 Three types of leases are recognized in the SNA; operating leases, ~~financial~~finance leases and resource leases. Each of these leases relates to the use of a non-financial asset. Fundamental to the distinction between the different sorts of leases is the difference between legal and economic ownership. This distinction is elaborated in chapter 34. The legal owner of an asset is the institutional unit entitled in law and sustainable under the law to claim the benefits associated with the asset. By contrast, the economic owner of an asset is entitled to claim the benefits associated with the use of the asset in the course of an economic activity by virtue of accepting the associated risks. The legal owner is often the economic owner also. When they are different, the legal owner has divested itself of the risks in return for agreed payments from the economic owner. In this section, the treatment of operating and finance leases are described. Section C includes discussion of resource leases.

### **1. Operating leases**

~~17.6~~27.5 *An operating lease is ~~one where~~ a contract between a lessor and a lessee, under which the lessor charges a rental to the lessee for the use of a produced non-financial asset, and the lessor remains the legal owner is also the ~~and~~ economic owner and accepts the operating risks and receives the economic benefits from the asset by using it in a productive activity of the asset.* One indicator of an operating lease is that it is the responsibility of the legal owner to provide any necessary repair and maintenance of the asset. Under an operating lease the asset remains on the balance sheet of the lessor.

~~17.7~~27.6 The payments made under an operating lease are referred to as rentals and are recorded as payments for a service. The character of operating leases may most easily be described in relation to equipment since operating leases often concern vehicles, cranes, drills etc. In general, though, any sort of non-financial asset, ~~an~~including intellectual property ~~product or a non-financial asset~~products, may be subject to an operating lease. The service provided by the lessor goes beyond the mere provision of the asset. It includes other elements such as convenience and security, which can be important from the user's point of view. In the case of equipment, the lessor, or owner of the equipment, normally maintains a stock of equipment in good working order that can be hired on demand or at short notice. The lessor must normally be a specialist in the operation of the equipment, a factor that may be important in the case of highly ~~complicated~~technical equipment, such as computers, where the lessee and ~~his~~its employees may not have the necessary expertise or facilities to service the equipment properly themselves. The lessor may also undertake to replace the equipment in the event of a serious or prolonged breakdown. In the case of a building, the lessor is responsible for the structural integrity of the building, so would be responsible in the case of damage due to a natural disaster, for example, and is usually responsible for ensuring that elevators, heating and ventilation systems function adequately.

~~17.8~~27.7 Operating leasing developed originally to meet the needs of users who require certain types of equipment only intermittently. Many operating leases are still for short periods though the lessee may renew the rental when the period expires and the same user may hire the same piece of equipment on several occasions. However, with the evolution of increasingly complicated types of machinery, especially in the electronics field, the servicing and backup facilities provided by a lessor are important factors that may influence a user to rent. Other factors that may persuade users to rent over long periods rather than purchase are the consequences for the enterprise's balance sheet, cash flow or tax liability.

### **2. ~~Financial~~Finance leases**

~~17.9~~27.8 *A financial lease is ~~one where~~ a contract between a lessor and a lessee, under which the lessor, as legal owner of an asset ~~passes the economic~~, substantially conveys the risks and rewards of ownership of the asset to the lessee ~~who then accepts the operating risks and receives~~. The lessee, therefore, becomes the*

*economic benefits from using owner of the asset in a productive activity.* In return, the lessor accepts another package of risks and rewards from the lessee. It is frequently the case that the lessor, though the legal owner of the asset, never takes physical delivery of the asset but consents to its delivery directly to the lessee. One indicator of a financial lease is that it is the responsibility of the economic owner to provide any necessary repair and maintenance of the asset. Under a financial lease, the legal owner is shown as issuing a loan to the lessee with which the lessee acquires the asset. Thereafter the asset is shown on the balance sheet of the lessee and not the lessor; the corresponding loan is shown as an asset of the lessor and a liability of the lessee. Payments under the financial lease are treated not as rentals but as the payment of interest and repayment of principal. If the lessor is a financial institution, part of the payment is also treated as a service charge (FISIM implicit financial services on loans and deposits).

~~17.10~~27.9 Very often the nature of the asset subject to a financial lease may be quite distinct from the assets used by the lessor in ~~his~~their productive activity, for example a commercial airliner legally owned by a bank but leased to an airline. It would make no economic sense to show either the aircraft or its ~~consumption of fixed capital depreciation~~ in the accounts of the bank or to omit them from the accounts of the airline. The device of a financial lease avoids this undesirable form of recording the ownership of the aircraft and the decline in its value while keeping the net worth of both parties correct throughout the length of the lease.

~~17.11~~27.10 It is common for a financial lease to be for the whole of the life of the asset, but this need not necessarily be so. When the lease is for the whole of the life of the asset, the value of the imputed loan will correspond to the present value of the payments to be made under the lease agreement. This value will cover the cost of the asset and include a service fee charged by the lessor. Payments made regularly to the lessor should be shown as a payment of interest, ~~possibly a repayment of principal and a service fee. If the lessor is a financial institution, the interest payment should be partitioned to record a payment for a service and a repayment of capital.~~ implicit financial services on loans and deposits. If the terms of the agreement do not specify how these ~~three~~ items are to be identified, the repayment of principal should correspond to the decline in the value of the asset (the ~~consumption of fixed capital depreciation~~), the interest payment to the return to capital on the asset (including any implicit financial services on loans and deposits) and the service ~~charge~~ fee to the difference between the total amount payable and these two elements.

~~17.12~~27.11 When the lease is for less than the whole life of the asset, the value of the loan should still be estimated as the value of the asset plus the value of the service charges to be made under the terms of the lease. At the end of the lease, the asset ~~will appear on the balance sheet of the lessee and its~~ value will be equal to the value of the loan owed to the lessor at that time. At that point the asset could be returned to the lessor to cancel the loan or a new arrangement, including the outright purchase of the asset, may be reached between the lessor and lessee. Because a financial lease requires the lessee to acquire substantively all the risks and rewards associated with the asset, if the lease is for less than the expected life of the asset, the lease usually specifies the value to the lessor at the end of the lease or the terms under which the lease can be renewed. Any variation in the price of the asset from the value in the lease agreement is borne by the lessee.

27.12 From a conceptual point of view, the transfer of leased assets at the end of the lease period should be recorded as extinguishing the financial claim of the lessor (and the corresponding liability of the lessee) that has been progressively built up over the leasing period. In practice however, it is considered appropriate to ignore the progressive recording of these financial claims, and to instead record the transfer of the relevant assets as capital transfers at the end of the lease period. In certain circumstances, however, particularly where there is a high degree of certainty that the asset will be transferred and where the value of that asset at the time of the transfer will be significant, a recording of building up a financial claim (and associated liability) should be preferably applied.

~~17.13~~27.13 Although a financial lease will typically be for several years, the duration of the lease does not determine whether the lease is to be regarded as an operating or financial lease. In some cases, a large complex such as an airport or even a building may be leased for short periods, perhaps only one year at a time, but on condition that the lessee takes all responsibility for the asset, including all maintenance and cover for exceptional damage, for example. Even though the lease period is short, and even though the lessor may not be a financial institution, if the lessee must accept all the risks associated with the use of the asset in production as well as the rewards, the lease is treated as a financial and not an operating lease and the asset appears on the balance sheet of the lessee with a corresponding loan extended from the lessor to the lessee.

~~17.14~~27.14 As a consequence, any corporation that specializes in this sort of leasing, even though it may be

called a property company or aircraft leasing company, should be treated as a financial corporation offering loans to the units leasing assets from them. If the lessor is not a financial corporation, the payments are split into repayments of principal and interest only; if the lessor is a financial corporation, the interest is split into SNA interest and a service charge ([FISIM implicit financial services on loans and deposits](#)).

27.12

## 2. Resource leases

27.13

27.8 A resource lease is an agreement whereby the legal owner of a natural resource that the SNA treats as having an infinite life makes it available to a lessee in return for a regular payment recorded as property income and described as rent. The resource continues to be recorded on the balance sheet of the lessor even though it is used by the lessee. By convention, no decline in value of a natural resource is recorded in the SNA as a transaction similar to consumption of fixed capital.

27.9 The classic case of an asset subject to a resource lease is land but natural resources are also generally treated in this way. An exception, when a long term lease of land may be taken as the sale of the land is described in paragraph 17.328.

27.10 Payments due under a resource lease, and only such payments, are recorded as rent in the SNA. There is further discussion of leases on natural resources in the following section.

27.14

## K.C. Licences and permits Rights to use a natural resource

17.18 27.15 As noted above, in many countries permits, rights to use natural resources are generally issued by government since government claims ownership of the resources on behalf of the community at large. However, the following treatments are described using this general starting point, however, the same treatments apply if the resources are privately owned.

17.19 27.16 There are basically three different sets of conditions that may apply to the use of a natural resource. The first, the legal owner may permit the resource to be used to extinction. The and thus transfers economic ownership of the resource. Second, the legal owner can extend or withhold permission to continued use of the resource from one year to the next and thus retains economic ownership of the resource. Third, the legal owner may allow the resource to be used for an extended period of time in such a way that in effect the user controls the use of the resource during this time with little if any intervention from the legal owner. The Under the third option the economic ownership of the resource is shared to the extent that both the user and the legal owner can extend or withhold permission to continued are entitled to future economic benefits from the use of the asset from one year to the next resource.

27.17 The first option results in the sale (or possibly an expropriation) of the asset. This is recorded as a transaction in the capital account with corresponding changes in the balance sheets of the two institutional sectors involved.

27.18 The second option leads involves treatment of the use as a resource lease. A resource lease is an agreement whereby the legal owner of a natural resource makes it available to a lessee in return for a regular payment recorded as property income and described as rent. The value of the natural resource continues to be recorded on the balance sheet of the lessor even though it is used by the lessee to the extent that the balance of risks and rewards is held by the lessor. The classic case of a natural resource subject to a resource lease is land but other natural resources may also be treated in this way depending on the circumstances surrounding the rights to use the resource.

27.19 The third option involves recording the creation of an asset for the user, distinct of the natural resources and an asset for the legal owner following the split-asset approach. The total value of these two assets is equal to the total value of the natural resource with the allocation of the total value between the user and the legal owner reflecting their respective shares of the future economic benefits to be earned from the resource itself but where the value exploitation of the resource and. Under the third option, depending on the asset allowing use nature of the agreement, regular payments of rent are linked. The third option comes back to the

27.2

~~treatment of the use as a resource lease, typically paid by the user to the legal owner.~~

~~17.20~~ 27.20 The difference in treatment between the ~~second and third options~~ ~~was articulated in the context of the case of a mobile phone licence and that recommendation (see SNA News and Notes Volume 14, (United Nations, 2002)) is recapitulated~~ depends on a range of criteria concerning the agreement established between the legal owner and the unit using the natural resource in production. The general criteria are presented first before ~~seeing~~ describing how each of the three options relates to different types of natural resources.

~~27.15~~ The “mobile phone” treatment of licences or permits to use a natural resource

~~27.16~~

~~27.17~~ The case arose in 2000 when the sale of licences to use radio spectra for third generation mobile phones brought a flurry of interest from companies wanting to have exclusive access to the spectra and who in consequence were prepared to bid (often by auction) extremely large sums for the access rights to the spectra.

~~27.18~~

~~27.19~~ Eight conclusions were agreed in respect of the mobile phone licences. Allowing for updated terminology, these were:

~~27.20~~

~~27.21~~ The spectrum constitutes a natural resource.

~~27.22~~ The licence to use the spectrum constitutes an asset described as a permission to use a natural resource which is a subset of the general asset class of contracts, leases and licences.

~~27.23~~

~~27.24~~ Typically licence payments are neither taxes nor purchases of the spectrum itself.

~~27.25~~

~~27.26~~ Land, mineral deposits and the spectrum are similar types of assets and so are leases and licences based on the use of those assets.

~~27.27~~

~~27.28~~ There is no single, universal and clear cut criterion to distinguish between rent and asset sale; a range of criteria needs considering.

~~27.29~~

~~27.30~~ Most cases examined point to treating licence payments as the purchase of an asset, not rent.

~~27.31~~

~~27.32~~ The value of the licence and the value of the spectrum move symmetrically.

~~27.33~~

~~27.34~~ Further elaboration will be useful in future.

~~27.35~~

~~27.36~~ The considerations referred to under conclusion (e) were six in number and are reproduced below.

~~27.37~~

27.21 There are six general criteria in distinguishing between the options.

- a.—*Costs and benefits assumed by licensee/user*: the more of the risks and benefits associated with the right to use an asset are incurred by the licensee/user, the more likely the classification of a transaction as the sale of an asset ~~as opposed to rent~~. Thus, ~~preagreement~~ pre-agreement on the value of payments (whether by lump sum or by instalments) effectively transfers all economic risks and benefits to the licensee/user and so point to the sale of an asset. If, on the other hand, the value of payment is made contingent on the results from using ~~use of~~ the ~~licensee~~ rights, risks and benefits are

27.4

only partially transferred to the licensee and the situation is more readily characterized as payment of rent. In the case of mobile phone licensees, the total amount payable has often been pre-agreed: a resource lease or split ownership. An additional indication of the degree to which commercial risks have been passed to the licenseeuser is to examine the hypothetical case where a licenseeuser goes

b. —

27.38a. — bankrupt. If, in such a case, the licensorlegal owner reimburses none of the upfront payment made by the licenseeuser, this would constitute a strong case againstfor a characterization of the transaction as rentsale of an asset, as apparently the licenseeuser has incurred all the commercial risks involved.

a.b. *Upfront payment or instalment*: as with other indicators, the mode of payment is in itself not conclusive for a characterization as asset or rent payment under one of the options. Generally, the means of paying for a licensee rights to use is a financial issue and as such not a relevant factor in determining whether or not it is an asset the treatment. However, business practice shows that upfront payments of rent for long periods (15-25 years in the case of mobile phone licensees) are highly unusual and this favours an interpretation would then favour treating the rights to use as sale of an asset.

a.c. *Length of the licensee: licensee contract: rights* granted for long periods suggest a treatment as the sale of an asset, while those granted for shorter periods suggest a treatment as payments for rent. The time frame involved in mobile phone licensing (15-25 years) is considered rather unusual as a period for which to conclude a fixed payment of rent and therefore a further indication favouring an interpretation as sale of an asset resource lease.

b.d. *Actual or de facto transferability*: the possibility to sell the licensee rights is a strong indication of economic ownership and if transferability exists, this is considered a strong condition to characterize the licensing act establishment of rights as the sale of third-party property rights. In practice, mobile phone licensee rights are often transferable either directly (by the enterprise selling the licensee rights to another enterprise) or indirectly (through the enterprise being acquired through a takeover).

e.e. *Cancellation possibility*: the stronger the restrictions on the issuer's capacity to cancel the licensee rights at its discretion, the stronger the case for treatment as a sale of an asset. Conversely, when licensee rights can easily be cancelled at the discretion of the issuer, economic ownership over benefits and risks has not been fully transferred to the licenseeuser and the transaction treatment qualifies more readily as rent a resource lease or split ownership.

d.f. *Conception in the business world and international accounting standards*: businesses, in accordance with international accounting standards, often treat a licensee right to use the spectrum natural resources as an asset. Again, in itself this does not lead to require treatment as an asset in the national accounts, and there are other areas where companies choose to present figures in their accounts in ways that are not consistent with the national accounts. But the treatment of the acquisition of mobile phone licensee rights as capital investment in company accounts provides an added incentive to treat them in a similar way in the national accounts, either as the sale of an asset or as split ownership.

27.22 Not all these considerations criteria have to be satisfied to characterize the licensee a right to use as a sale of an asset nor does a simple majority of them being satisfied do so. However, in order to qualify as a rental agreement resource lease, at least some of the following sorts of conditions criteria should hold.

- a. The contract is of *short-term duration*, or renegotiable at short-term intervals. Such contracts do not provide the lesseeuser with a benefit when market prices for the leased asset resource go up in the way that a fixed, long-term contract would. Such benefits are holding gains that typically accrue to economic owners of assets.
- b. The contract is *non-transferable*. Non-transferability is a strong but not a sufficient criterion for the treatment of licensee payments as rent resource leases, because, although it such a contract precludes the lesseeuser from cashing in on benefitting from holding gains, it does not preclude the lesseeuser from reaping comparable economic benefits (for example, using the licensee resource in their business).

- c. The contract contains *detailed stipulations* on how the lesseeuser should make use of the assetresource. Such stipulations are often seen in cases of rentuse of land, in which the legal owner wishes to retain a control over the usage of the land. In the case of licenseeother cases, examples of such stipulations would be that the contract states what regions or types of customers should be served, or that it sets there are limits on the prices that the lesseeuser may charge.
- d. The contract includes conditions that give the lessorlegal owner the *unilateral right to terminate* the leaseright to use without compensation, for instance for underuse of the underlying asset by the lesseeuser.
- e. The contract requires *payments over the duration of the contract, rather than a large upfront payment*. Although this conditioncriterion is essentially financial in character and thus cannot be decisive on the type of the leasetreatment, it may indicate a degree of control for the lessorlegal owner to direct the use of the spectrumresource. The case for a treatment as renta resource lease is further supported if the payments are related to the revenue the lesseeuser derives from the licenseerights to use.

~~17.25~~27.23 These two sets of considerations can be seen as criteria reflect a more specific parallel to application of the distinction efbetween economic ownership from and legal ownership as used in distinguishing between an operating and financial lease as described above. The conditionsFurther, the criteria for treatment of the payment as the acquisition of an asset and for treatment as payment of renttransactions are indicative rather than prescriptive. AOnce a decision on the appropriate treatment when some of the conditions are not met will necessitateis made, further consideration of how to record those conditions not metthe actual transactions will be needed, accepting that not all criteria pointing to a specific treatment may be met. For example, if on balance the decision is to treat the paymentarrangement as renta resource lease but a large upfront payment was made, this payment should, in principle, be treated as a prepayment to be recorded on an accrual basis. However, if the recipient is not willing to consider a refund if the contract is suspended, accrual recording is difficult. This is one reason why upfront payments are often indicative of the sale of an asset rather than the payment of renta resource lease.

~~17.26~~27.24 The application of these principlescriteria to the main forms of natural resources is described below; beginning with radio spectra.  
six criteria quoted above are to be considered.

## 1. Land

~~17.31~~27.25 Land may be sold outright when the legal ownership is transferred from one institutional unit to another. (Land may not be recorded as being sold to a non-resident unit. In such cases a notional resident unit is created that holds title to the land; the non-resident unit then owns the equity of the notional resident unit.)

~~17.32~~27.26 The type of asset Land is the natural resource most frequently subject to a resource lease is land. Tenant farmers usually pay regular rent to their landlord. A resource lease outright to use land may be considered as a sale of the land if the leasecontract satisfies most or all of the same criteria as theseconsiderations listed above for payments for a mobile phone licensee to be considered atreatment as the sale of an asset. When the land is leasedused in other circumstances, the payments are recorded as rent under a resource lease agreement.

~~17.33~~27.27 In some jurisdictions, the land under buildings remains in the legal ownership of a landlord other than the owner of the buildings. If regular payments are made to the landlord, these are recorded as rent. However, it is sometimes the case that, even though the land legally belongs to another unit, the right to occupy it for an extended period is paid for in a single upfront payment often when the building is acquired. As explained in the previous section, this suggests recording the payment as the acquisition sale of the asset. In such a case, when the building changes ownership, the purchase price includes an element representing the present value of future rent payments. In such a case, the land is recorded in the SNA as if the ownership is transferred along with the building above the land. If, at the end of the land lease, a further payment is liable for extension of the lease for another long-term period, this should be recorded as capital formation and an acquisition of an asset in a manner similar to costs of ownership transfer on purchase and sale of an

asset.

27.39

## **2. Mineral and energy resources**

27.28 When a unit owning a mineral or energy resource cedes all rights over it to another unit, this constitutes the sale of the resource. Like land, mineral and energy resources can only be owned by resident units; if necessary a notional resident unit must be established to preserve this convention.

27.29 Most commonly, mineral and energy resources remain in the legal ownership of general government, with users extracting mineral or energy resources under an agreement where the payments made each year are dependent on the amount extracted. The payments (sometimes described as royalties) are recorded as rent. The full natural resource rent can be estimated using the residual value method, by deducting from output all costs related to the extractions of the resources, including services related to the capital used in production (for more details, see the annex to chapter 4). Natural resource rent paid on rights to use mineral and energy resources should be split between amount paid in relation to non-renewable mineral and energy resources and renewable energy resources. Where possible, the rent paid on specific high revenue generating resources (e.g. copper, oil) should be recorded separately.

27.30 The legal owner (in many but not all circumstances a government) often does not appropriate the full resource rent which can be derived from the exploitation of mineral and energy resources, and the asset in question may generate a future stream of natural resource rents (i.e. after accounting for returns to capital) beyond the payments of rent to the legal owner. In these cases, the unit having the rights to exploit the resources thus appropriates part of the resource rents, reflecting the future capital services derived from these assets by the unit having the exploitation rights. In these cases, the value of the resources in question is split between the legal owner and the unit exploiting the resources. (See also paragraphs 14.xxx (SNA). An example of this is provided in Section D below.

27.31 The generation of income from renewable energy resources does not require the extraction of minerals or energy resource but rather the construction and operation of produced assets which capture the energy from the renewable source. In this context, the relevant rights and permissions are directly associated with the location of the produced assets and the economic owner must secure the permissions before construction and operation. The treatment of any payments associated with the permissions will be the same as for payments for the use of land.

## **2.3. Timber resources**

27.32 Timber resources are a type of biological resource that are valued in terms of the expected harvesting of timber. Most commonly, timber resources are present in areas of forest land but the harvesting of timber, and hence the stock of timber resources, can occur in other areas of land, in particular agricultural land, for example through agro-forestry production systems. A clear distinction must be made between the value of timber resources and the value of the land, especially forest land, on which the stock of timber grows. By convention, the value of timber resources is measured in relation to the current, work-in-progress value of the stock of timber (both mature and immature trees that are expected to be harvested) while the value of forest and other land incorporates the value of future benefits from the harvesting of timber.

~~17.34~~27.33 If a unit is given permission to clear fell an area of ~~natural~~ forest land, or to fell at its discretion without any restriction in perpetuity, the payments made to the legal owner constitute the sale of an asset. (The sale of forested land may be recorded as the sale of the timber and the land separately, depending on the intended use of each.) forest land should be recorded as the sale of the timber resources and the land separately, where the value of the timber resources reflects the work-in-progress value of the current stock of timber, and the value of forest land reflects the value of future benefits from the land after deduction of the work-in-progress. In some countries, sales of standing timber are common where the owner of a forest manages the growth of trees but sells the stock of timber resources ahead of harvest with the purchaser taking on the task of felling the trees and selling the harvested timber. These transactions may provide a measure of the value of work-in-progress of the timber resources.

~~17.35~~27.34 The option to have a lease permitting felling at the lessee's discretion but subject to the restoration

of the land, in an acceptable forested state, at some time in the future is improbable. It is more common for timber felling to be allowed under strict limits with a fee payable per unit volume of timber felled (stumpage). ~~The limits are usually such that the harvest of timber is sustainable and so the payments are recorded as rent in the case of a natural forest fee).~~ These payments to the legal owner are recorded as rent. Rent may also be recorded in relation to the forest or other land on which the timber resources grow. The treatment of these payments should align with the treatment of land as described above. Where the natural resource rent from harvesting timber is greater than the payments of rent, the total value of the timber resources and the forest land should be partitioned following the split-asset approach.

~~Forests may also be produced assets, in which case the extraction of timber is treated as the sale of a product.~~

~~17.37~~ 27.35 ~~Illegal logging across national borders~~ is prevalent in some countries. In such cases the quantity of timber extracted should be recorded as uncompensated seizure of a natural resource ~~or cultivated asset, as the case may be.~~

27.40

### 3.4. Fish

27.36 Natural stocks of fish with an economic value are an asset and the same considerations apply to them as to other natural resources. Generally, the water bodies in which fish are caught are under the administration or management of economic units (usually government) that are not the same units as those catching the fish. Consequently, the government may be considered the legal owner of the fish. This would include for example fish stocks within the exclusive economic zone (EEZ) of a country. Alternatively, access to specific stocks of fish (e.g. tuna) may be “managed” (again by government) using quotas and other techniques to control the extent of the catch, in which case again the government may be considered the legal owner. Where there is evidence of management, a total value of the fish stock is equal to the net present value of the future natural resource rent estimated using the residual approach.

27.37 In cases where there is no effective management of the fish stock or an associated water body, then there is no legal owner and consequently no asset is recorded on the balance sheet notwithstanding the resource rent that may be earned by fisherman. This treatment is consistent with economic theory where the resource rent in open access fishery contexts will tend to zero and hence there will be no balance sheet value of the stock to record in an SNA context.

27.38 Depending on the organizational arrangements different accounting entries will be required. In some cases, the unit undertaking the fishing activity may be required to pay an annual fee to the legal owner. These payments should be recorded as rent. Where the natural resource rent is greater than this payment then a partitioning of the value of the fish stock can be made following the split asset approach.

27.39 In other cases, the legal owner may issue fishing quotas in perpetuity or for extended periods to particular institutional units, for example, where fishing is an established way of life and there may be little alternative economic employment. If the quotas are issued in perpetuity, either free of charge or for a fee, this is treated as the sale of an asset and the entire value of the fish stock is attributed to the holder of the quota (assuming that the holder is also undertaking the fishing activity). The difference between the sale price (potentially zero) and the full value of the fish stock should be recorded as the appearance of an asset in the other changes in the volume of asset account.

27.40 If quotas are issued for a certain period of time and have an associated price (perhaps established using an auction), then the value of the fish stock should be partitioned using the split-asset approach where the amount paid for the quota reflects the share of the value of the fish stock attributable to the legal owner (i.e. the unit issuing/selling the quota) and the remaining part of the net present value of the future natural resource rent is attributed to the quota holder. Depending on the quota pricing arrangements, the price (e.g. the auction price) may represent a good approximation of the net present value at the time of the transaction noting the need for re-assessment of the value in future periods.

27.41 Payments made in relation to the quota are treated as payments of rent. If these payments are annual, then no additional consideration is required. However, if a payment relates to more than one year, then entries in the financial account will be required to reflect the prepayment of rent as part of accounts payable and receivable.

27.42 If the quotas, after issuance or sale, can be transferred by the original holder, then a market in quotas may be established. Although they have a market value, these quotas do not have additional or separate value beyond the total value of the fish stock as measured using the net present value of the natural resource rent. In concept, there should be a good alignment between the value of the marketed quotas and the value of the fish stock.

27.43 In the event that the quota is held by an economic unit other than the unit undertaking the fishing activity, then the total value of the fish stock should be partitioned using the split asset approach with the share attributable to the quota holder equal to the market value of the quota and the remaining value attributable to the unit undertaking the fishing activity.

~~17.38~~27.44 It is not realistic to consider that permission would be given to exhaust fish stocks but illegal fishing may either reduce the stock below the point of sustainability or exhaust them altogether. In these cases, uncompensated seizure of the stock should be recorded.

~~27.41~~ Fishing quotas may be allocated in perpetuity or for extended periods to particular institutional units, for example, where fishing is an established way of life and there may be little alternative economic employment. In such circumstances the quotas may be transferable and if so, there may be a well developed market in them. Fishing quotas may therefore be considered as permits to use a natural resource that are transferable. They are thus assets in the SNA.

~~27.42~~

~~27.43~~ An alternative regime is to issue a permit for a strictly limited period of time, less than a year, to a nominated institutional unit, often a non resident. This is a common practice in some islands in the South Pacific, for example. In these cases the revenue from the licences should be recorded as rent as under a resource lease.

~~27.44~~

~~17.41~~27.45 A licence for recreational fishing has long been considered, by convention, as payment of a tax- (see para 9.xx). This treatment is not changed by the wider considerations for commercial fishing.

27.45

## **4.5. Water**

~~17.42~~27.46 A body of water with an economic value can be sold in its entirety either as part of the land that surrounds it or as a separate entity.

~~17.43~~27.47 ~~As is the case for fish, it~~ It is unlikely that economic ownership would be ceded under a long lease with no preconditions on the quantity and state in which a similar amount of water should be returned available to the legal owner in which case payments would generally be treated as rent. However, it is possible that surface water could be leased under a long lease for recreational purposes, say. The treatment of such leases should be as for land.

~~17.44~~27.48 ~~Of increasing concern is~~Concerning the extraction of water from water bodies. ~~Regular, regular~~ payments to the legal owner for the ~~extraction of~~right to abstract water (as opposed to payments for the delivery or supply of water) should be treated as rent.

27.46

## **4.6. Radio spectra**

27.49 Payment for a mobile phone licence constitutes the sale of an asset, not payment for rent, when the licensee acquires effective economic ownership rights over the use of the spectrum. To decide whether ownership is effectively transferred or not, the criteria quoted above are to be considered.

~~17.28~~27.50 When sale of an asset applies and when the life span of the licence and of the spectrum coincide, the payment for a licence is treated as the sale of the spectrum itself. The latter situation applies always when licences are granted indefinitely.

~~17.29~~27.51 When sale of an asset applies, and when the life span of the licence is different from the life span of the spectrum, the payment for a licence is treated as the sale of a permit to use a natural resource by the legal owner (licensor) to the economic owner (licensee).

27.2

~~17.30~~27.52 When the licence agreement is treated as the sale of an asset in its own right, its value is established at the time of its sale. It declines with the expiration of the period of validity to fall to a value of zero at the point of the expiry of the licence. Symmetrically, the value of the spectrum to the lessor falls when the licence acquires a value and is progressively re-established as the licence expires. This is consistent with a potential further sale of the right to use the spectrum for another period. This procedure also ensures a neutral effect on the net worth of the overall economy during the life of the licence.

27.47

27.48 Mineral resources

27.49

~~17.45~~27.51 Mineral resources differ from land, timber and fish in that although they also constitute a natural resource, there is no way of using them sustainably. All extraction necessarily reduces the amount of the resource available for the future. This consideration necessitates a slightly different set of recommendations for how transactions relating to their use should be recorded.

27.50 When a unit owning a mineral resource cedes all rights over it to another unit, this constitutes the sale of the resource. Like land, mineral resources can only be owned by resident units; if necessary a notional resident unit must be established to preserve this convention.

27.51

27.52 When a unit extracts a mineral resource under an agreement where the payments made each year are dependent on the amount extracted, the payments (sometimes described as royalties) are recorded as rent.

27.53

27.54 The owner (in many but not all circumstances government) does not have a productive activity associated with the extraction and yet the wealth represented by the resource declines as extraction takes place. In effect, the wealth is being liquidated with the rent payments covering both a return to the asset and compensation for the decline in wealth. Although the decline in wealth is caused by the extractor, even if the resource were shown on the balance sheet of the extractor, the rundown in wealth would not be reflected in the extractor's production account because it is a non-produced asset and thus not subject to consumption of fixed capital. (The SEEA 2003 describes a form of satellite account where such a deduction from national income can be made for minerals as well as for other natural resources used unsustainably.) For these reasons, simple recording of payments each year from the extractor to the owner as rent and changes in the size and value of the resource as other changes in the asset accounts of the legal owner is recommended.

27.55

## **L.D. Sharing assets**

~~17.49~~27.53 There are two ways in which assets may be shared. The asset may be wholly owned by two or more units, each at different points in time, through successive purchases or transfers. Alternatively, the risks of and benefits from the asset may be shared by two or more units at a single point in time. The two cases require different treatments.

~~17.50~~27.54 Within the SNA, even though the asset may be owned by different units at different times, when a balance sheet is drawn up, in most cases the whole of the value of the asset is attributed to one unit. (The exceptions relate to unincorporated joint ventures and split assets for certain natural resources, which are discussed below.) For an asset subject to an operating lease, there is no ambiguity. The legal owner is also the economic owner and is the unit that shows the asset on its balance sheet. For an asset subject to a financial lease, the unit showing the asset on its balance sheet is the economic owner. The value of the asset is the present value of the future payments due to the legal owner plus the value of the asset at the end of the lease as specified in the lease agreement. This is consistent with the view that the value of the asset represents the stream of future benefits coming from the asset and the economic owner is the unit entitled to receive these benefits in return for accepting the risks associated with using the asset in production. For an asset subject to a resource lease, the value is shown on the balance sheet of the legal owner.

~~17.51~~27.55 When licences rights to use natural resources such as radio spectra, land, timber and fish and land satisfy

the “mobile phone” criteria; described in Section C above such that a sale of an asset is recorded then a separate asset, described as a permit to use a natural resource, is established. These assets are part of the subclass of contracts, leases and licences. They are then shown on the balance sheet of the licensee.

~~17.52~~27.56 ~~Sharing the risks and rewards of an asset between different units at a point in time is unusual.~~

~~The~~Regarding the use of assets, the most common occurrence is that a single unit undertakes the activity in which the asset is used and that unit shares the returns among the owners in the form of distributed property income. However, occasionally it is possible such a single unit does not exist and it is not meaningful to try to create it statistically. This is most common when the participating units are resident in different economies, as may be the case with an airline, or in the case of some unincorporated joint ventures (UJVs). The terms under which UJVs are established are diverse but one form allows that all members share the assets equally. In such cases, the SNA records the assets shared between the owners in proportion to their ownership shares.

~~17.53~~27.57 In some joint ventures, one party may contribute an asset as its share of the costs. If this happens, an injection of capital equal to the value of the asset should be recorded followed by the purchase of the asset in question with the ownership of the asset then shared by all parties to the arrangement.

27.58 ~~Permits~~In relation to the use of natural resources, as described in Section C above, there will be instances where the future stream of benefits in the form of natural resource rent are shared between the legal owner and the extractor of the resources. The recording in these situations should follow the split asset approach as discussed above and in chapters 4 and 11.

27.59 To illustrate the split-asset approach the following example is provided. It shows the range of entries that are associated with a full implementation of the approach, including accounting for depletion as a cost of production and allocation of depletion in line with the allocation of income generated by the extraction of natural resources. The production account of the extractor records output of 100 and costs of remuneration of employees (35) and depreciation (20) resulting in net operating surplus of 0 with natural resource rent equal to 45. Rent on natural resources of 30 is paid to the government as recorded in the distribution of income account and this is all considered depletion such that net saving of both the government and the extractor is zero. In the capital accounts of the extractor depreciation (20) and the remaining share of depletion (15) are deducted to derive net lending of 35. For government, the depletion of resources derives a net lending of 30.

~~27.56~~27.60 In terms of changes in the balance sheet, it is assumed that the natural resource rent (45) from exploiting the natural resources (valued at 750 at the beginning of the period) are split between government (30) and the extractor (15). Effectively, this means that government is giving up 1/3 of the natural resources. The latter is recorded, in the accounts of the legal owner, as a negative other change in volume of natural resources with a value of (minus) 250. This recording follows economic reality, with government foregoing part of the future natural resource rents. Even though governments may receive a steady flow of future income, if it only represents part of the potential benefits from the natural resources, then the recording of a reduction in balance sheet value makes evident that government is redistributing wealth.

Table 27.1: Entries for the split-asset approach

Accounts for the extractor of natural resources					Accounts for the government						
Production and generation of earned income account					Production and generation of earned income account						
Remuneration of employees	35	Output	100		Remuneration of employees	0	Output	0			
Depreciation	20				Depreciation	0					
Depletion/degradation of natural resources	45										
Net operating surplus	0				Net operating surplus	0					
Allocation of earned income account					Allocation of earned income account						
Natural resource rent	30	Net operating surplus	0				Net operating surplus	0			
Depletion/degradation borne by government	-30						Natural resource rent	30			
							Depletion/degradation borne by government	-30			
Net saving	0				Net saving	0					
Capital account					Capital account						
Acquisition of assets	0	Net saving	0		Acquisition of assets	0	Net saving	0			
Depreciation	-20	Net capital transfers received	0		Depreciation	0	Net capital transfers received	0			
Depletion/degradation of natural resources	-15				Depletion/degradation of natural resources	-30					
Net lending/borrowing	35	Changes in NW due to saving and CT	0		Net lending/borrowing	30	Changes in NW due to saving and CT	0			
Financial account					Financial account						
Cash	35	Net lending/net borrowing	35		Cash	30	Net lending/net borrowing	30			
Other changes in the volume of assets and liabilities account					Other changes in the volume of assets and liabilities account

Total	200	450	Total	200	450	Total	750	500	Total	750	500

## B.E. Permission to undertake a specific activity

~~27.57~~27.61 In addition to ~~licences and leases~~ and rights to use an asset as described in the previous sections, permission may be granted to engage in a particular activity, quite independently of any assets involved in the activity. Thus ~~permission rights~~ to extract minerals in return for the payment of rent, for example, is not covered by this type of ~~permit. The permits~~permission. Permissions are not dependent on a qualifying criterion (such as passing an examination to qualify for permission to drive a car) but are designed to limit the number of individual units entitled to engage in the activity. Such ~~permissions, often in the form of permits or licences,~~ may be issued by government or by private institutional units and different treatments apply to the two cases. In general however, it is noted that the accounting entries should follow the treatment explained in 13.34 concerning valuation, revaluation and other changes in volume.

### 1. PermitsPermissions issued by government

~~17.55~~27.62 When governments restrict the number of cars entitled to operate as taxis or limit the number of casinos permitted by issuing licences, for example, they are in effect creating monopoly profits for the approved operators and recovering some of the profits as the fee. In the SNA these fees are recorded as taxes, specifically as other taxes on production. This principle applies to all cases where government issues ~~licences~~permissions to limit the number of units operating in a particular field where the limit is fixed arbitrarily and is not dependent only on qualifying criteria.

~~17.56~~27.63 In principle, if the ~~licence~~permission is valid for several years, the payment should be recorded on an accrual basis with an other account receivable or payable entry for the amount of the ~~licence fee~~payment covering future years. However, if government does not recognize a liability to repay the ~~licencee~~user in the case of a cancellation, the whole of the fee payable is recorded at the time it is paid.

27.64 The incentive to acquire such a ~~licence~~permission is that the ~~licencee~~user believes that ~~he~~they will thereby acquire the right to make monopoly profits at least equal to the amount ~~he~~ paid for the ~~licence~~permission. This stream of future income is treated as an asset if the ~~licencee~~user can realize this by on-selling the ~~asset rights~~. The type of asset is described as a permit to undertake a specific activity. The value of the asset is determined by the value at which it can be sold or, if no such figure is available, is estimated as the present value of the future stream of monopoly profits. If the payment for the ~~licence~~permission is being recorded by government on an accrual basis, the ~~licencee~~user has an asset in ~~his~~the balance sheet under accounts receivable or payable equal to the value of the future payments and so the value of the ~~licence~~permission itself should cover simply the excess of the monopoly profits over the cost. If the ~~licence~~permission is on-sold, the new owner assumes the right to receive a refund from the government if the ~~licence~~permission is cancelled as well as the right to earn the monopoly profits. If the ~~licence~~permission was recorded as a single tax payment, the value of the asset is determined by the value at which it can be sold or, if no such figure is available, is estimated as the value of all the future monopoly profits without deduction. The ~~asset first appears in appearance of the asset, as well as the changes in value over time, are recorded in the~~ other changes in the volume of assets and liabilities account ~~and changes in value, both up and down, are recorded in the revaluation account.~~

~~17.57~~

### An example

~~17.58~~27.65 Suppose a unit, A, contracts with government to buy a permit to operate a casino for 3 years at a total cost of 12. ~~He~~The unit expects to make monopoly profits of 7 per year because the permit excludes many other casinos from operating. The government may or may not be prepared to make a refund if A ~~relinquished~~relinquishes the permit. A may utilize the permit for the whole of the 3 years for which it is valid or ~~he~~ may sell it to unit B at the end of year 1. The recordings under these four possibilities are examined below.

27.58

*Case 1: Government does not offer a refund and A keeps the permit for 3 years*

~~17.59~~27.66 At the start of year 1, A pays tax of 12 and has an asset worth 21 initially. By the end of the year, the value of the asset has reduced by 7 as an other volume change, because one of the three years for which the permit was initially valid has expired. At this point the asset is contributing 14 to ~~his~~A's net worth. By the end of the second year ~~he~~A writes off another 7 as an other volume change, leaving a contribution to net worth of 7. By the end of the third year the asset is worth zero.

~~27.59~~

*Case 2: Government does not offer a refund and A sells the permit to B after one year*

~~17.60~~27.67 At the start of year 1, A pays tax of 12 and has an asset worth 21 initially. By the end of the year the value of the asset has reduced by 7 as an other volume change, because one of the three years for which the permit was initially valid has expired. At this point ~~he~~A values the asset at 14. However, B is only prepared to pay 13 for the asset and A accepts this. A therefore reduces the value of the asset by 1 as a revaluation change. B then acquires the asset and reduces its value by 6.5 in the other change in volume of assets account in each of the two following years.

~~27.60~~

*Case 3: Government does offer a refund and A keeps the permit for 3 years*

~~17.61~~27.68 At the start of year 1, A makes a payment of 12 to government but this is recorded as a payment of tax of 4 during the year and at the end of the year government has an account payable to A of 8. The value of the permit to A is only the excess of the monopoly profit over the total amount that A will have to pay to government. This starts at 9 (the difference between 7 and 4 for three years) but by the end of year 1 is worth only 6. At the end of the year A's net worth includes an account receivable from government of 8 and 6 as the remaining value of the permit. The total is 14 as in case 1. During the second year, A's account receivable from government is reduced by 4 which is used to pay the tax due in year 2. In that year the value of the permit also reduced by 3 from 6 to 3. At the end of the year, A's net worth includes an account payable from government of 4 and a permit worth 3, total 7 as in case 1. At the end of year 3, both the account payable and the value of the permit are reduced to zero.

~~27.61~~

*Case 4: Government does offer a refund and A sells the permit to B after one year*

~~17.62~~27.69 At the start of year 1, A makes a payment of 12 to government but this is recorded as a payment of tax of 4 during the year and at the end of the year government has an account payable to A of 8. The value of the permit to A is only the excess of the monopoly profit over the account payable. This starts at 9 (the difference between 7 and 4 for three years) but by the end of the year is worth only 6. At the end of the year A's net worth includes an account receivable from government of 8 and 6 as the remaining value of the permit. The total is 14 as in case 1. As in case 2, A has to reduce the value of ~~his~~the permit (in this case from 6 to 5) when ~~he~~A appears to sell the asset to B for 13. In fact, the account payable from government of 8 is transferred to B and the asset is sold for 5. B's net worth is unchanged. ~~He~~B has paid A 13 but received the account payable of 8 and an asset valued at 5 in return. In year 2, the account payable is reduced by 4 and a tax payment of 4 is recorded and the permit declines in value from 5 to 2.5.

~~27.62~~

**Government ~~permits~~permissions as assets**

~~17.63~~27.70 A permitpermission issued by government to undertake a specific activity may be treated as an asset by the holder of the permission only when all the following conditions are satisfied:

- a. The activity concerned does not utilize an asset belonging to government; ~~if it does the permission to use the asset is treated as an operating lease, a financial lease, a resource lease or possibly the acquisition of an asset representing permission to use the asset at the discretion of the licensee over an extended period;~~
- b. The permitpermission is not issued subject to a qualifying criterion; payments for such

~~permits~~permissions are treated as ~~either taxes or payments for services~~;

- c. The number of ~~permits~~permissions is limited and so allows the holder to make monopoly profits when undertaking the activity concerned;

a.d. The ~~permit~~ holder must be legally and practically able to sell the ~~permit~~permission to a third party.

~~17.64~~27.71 ~~Even if all these conditions are satisfied, if in~~In practice, ~~if~~ the ~~permits~~permissions are not on-sold, it is not relevant to record the ~~permits~~permissions as assets, ~~even if all of these conditions are satisfied~~. If any of the conditions is not satisfied, the payments are treated as taxes without the creation of an asset in the category of contracts, leases and licences. (There may be an account payable as shown in cases 3 and 4 of the example.)

27.63

## 2. PermitsPermissions issued by other units

~~17.65~~27.72 It is less common for units other than government to be able to limit the participation in a given activity. One instance may be when it is either compulsory or desirable to belong to a professional association but in this case there is seldom a limit on numbers participating. Another example could be where the owner of property limits the numbers of units allowed to operate on ~~his~~the property for example a hotel with a policy of only allowing one taxi firm to pick up guests. In these sorts of cases, ~~the permits any related payments~~ are treated as payments for services. In principle the payment should be recorded on an accrual basis throughout the period for which the ~~permit~~permission is valid. There is no reason in principle why such ~~permits~~permissions could not be treated as assets if they were marketable though this may not be a common situation.

27.64

### Non-government permitspermissions as assets

~~17.66~~27.73 A ~~permit~~permission issued by a unit other than government to undertake a specific activity may be treated as an asset ~~by the holder of the permission~~ only when all the following conditions are satisfied:

- a. The activity concerned does not utilize an asset belonging to the ~~permit~~permission-issuer; if it does the permission to use the asset is treated as an operating lease, a financial lease or a resource lease;
- b. The number of ~~permits~~permissions is limited and so allows the holder to make monopoly profits when undertaking the activity concerned;
- c. The ~~permit~~ holder must be legally and practically able to sell the ~~permit~~permission to a third party.

~~17.67~~27.74 ~~Even if all these conditions are satisfied, if in~~In practice, ~~if~~ the ~~permits~~permissions are not on-sold, it is not relevant to record the ~~permits~~permissions as assets, ~~even if all of these conditions are satisfied~~. If any of the conditions is not satisfied, the payments are recorded as payments for a service.

27.65

## 2.3. PermitsPermissions to use ~~natural resource~~the environment as ~~sinks~~a sink

~~27.75~~ Governments are increasingly ~~turning to the~~issuing of emission permits as a means of controlling total emissions. ~~These~~An emissions permit (cap-and-trade) system is a flexible market mechanism that establishes a maximum level of pollution - a cap. Companies must have a permit to cover each unit of pollution they produce. Each permit stipulates the amount of emissions, for example greenhouse gases) that can be emitted (the quota). As such, each company must have a permit with a sufficient quota of units of emissions to cover their needs.

~~27.76~~ In the initial stages of some cap-and-trade schemes, permits are given to non-financial corporations freely. As a result, firms do not ~~involve the use of a natural~~incur any additional production costs, unless they exceed their quota and are required to purchase additional permits from others. Increasingly, governments are auctioning permits rather than giving them freely. In these auctions, the purchase of a permit is not restricted to the emitting entity - permits can be purchased by any market participant - individuals, investors, governments, non-profit institutions, financial and non-financial companies.

- 27.77 Nonetheless, the schemes are structured primarily for non-financial corporations, who are most likely to emit. If companies exceed their quota of emissions, they can purchase unused permits from others, adjust their production or in the longer-term, install technology that reduces emissions. Depending on the adaptability of firms' production functions, some firms will be able to adjust to the limits more easily than others.
- 27.78 The recommended approach for recording emission permit systems in the SNA is to record the issuing of the emissions permit as a financial asset ~~/~~ liability valued at the auction price. Thus, the issuance of permits is regarded as the purchase of a financial asset – accounts receivable / payable - where the payment grants the acquirer the right to emit a pre-specified quantity of emissions sometime in the future. This approach aligns with the recording of permits in company financial statements where the emitting corporation incurs an expense at the time of surrender of the permit, which impacts their net lending/ borrowing. In the SNA treatment, when the company surrenders the permit, it is recorded as taxes on production. Any change in price from the issuance date is "written off" in the revaluation account each time there is ~~no~~ a transaction. This ensures that the flow of taxes will always reflect the original issuing price and not the current market value placed on the atmosphere of the permit which could include holding gains or losses.
- 27.79 Emission permits provided freely to corporations do not have an associated tax cashflow. If taxes are maintained at issuance price (i.e. at zero), this implies that freely provided emission permits have zero value. ~~In so it cannot doing,~~ emission permits auctioned or provided freely will follow the actual cash revenue received by governments. However, the market value of emission permits (including freely provided ones) is clearly not zero. When emission permits are transacted amongst corporations, domestically or with non-residents they should be recorded in the accounts. If a corporation exceeds its quota and requires additional permits, it will purchase them from the market some of which could have been initially provided freely. Although, these are good arguments that could be considered to be an economic asset) and are therefore classified as taxes even though the permitted "activity" is one of creating an externality. It is inherent in the concept that the permits will be tradeable and that there will be an active market in them. The permits therefore constitute assets and should be valued at the market price for which they can be sold for emission permits issued freely to be assigned a value, it may be difficult to consistently assign values and countries may need to resort to imputations. Given the complexity, conceptual and practical difficulties, and notwithstanding the need for imputations, compilers should preferably not record any asset/liability for freely issued emission permits, and instead revalue them back to zero every time there is a transaction with an emission permit that was freely issued.
- 27.80 ~~The~~ It is important for users to be able to easily identify all transactions of emission permits in the accounts. In order for emission permits to be visible, it is recommended that a separate classification for emission permits be assigned that aligns with the new environmental classifications.
- 27.81 Methodologies and assumptions are needed to allow for time of recording, valuation, and other adjustments. It is assumed that the time the emission permit is surrendered corresponds to the time that emissions occurred. This assumption implies that the payments for emission permits issued by the government in year t will be recorded as tax revenue in year t+n. Adjustments are also needed to align corporate expenses reported in business accounts with government revenue and to record cross border transactions and stocks in relation to international or multi-country permit schemes / arrangements, such as the European Union Emission Trading Scheme (EU ETS).
- 27.82 To illustrate these concepts the following numerical example is provided. The starting point for the numerical example is that corporation A and corporation B have liquid assets (currency) of \$1000 and \$1500, respectively. The government then issues 100 emission permits at a price of \$10 each. The recording of the purchase of these permits by corporation A is rather straightforward. Government receives cash of \$1000 with the equivalent increase of liabilities (other accounts receivable/payable) representing the prepaid taxes on production, while corporation A pays \$1000 in cash with a concomitant increase in claims towards the government.
- 27.83 Next corporation A sells the permits to corporation B at a price of \$15 for each permit. To arrive at an appropriate recording, the claims are first revalued from \$1000 (= 100 \* \$10) to \$1500 (= 100 \* \$15), after which the claims are sold at the agreed market price, in exchange for cash, to corporation B. At this point the value of the financial claims of the government differs from the value of the corresponding claims in the books of corporation B. Since the treatment is that the value in the government accounts does not change (consistent with the surrender of the permits being recorded at issuance prices at a later moment in time), the

claims in the books of corporation B need to be revalued downwards. In the last stage of the example, half of the permits are surrendered. Here taxes on production are recorded with a counterpart decrease in the value of the financial claims.

27.84 It is noted that where emissions concern emissions to the atmosphere, an alternative recording may be envisaged if the atmosphere itself was treated as an asset. The SNA research agenda includes further consideration of the treatment of the atmosphere as an asset and, depending on the outcomes of that research, the treatment of emission permits may be revisited.

~~17.69~~27.85 Governments may also issue permissions to use the environment as sink without the use of trading schemes as described above. Payments may be made for these permissions. To describe the different ways of treating the payments, the case of payments for discharging water may be considered as an example of the different. Four alternatives are possible ~~ways of treating the payments~~.

27.51• If a payment to discharge water is a fine intended to inhibit discharge, it should be treated as a fine.

27.52• If a limited number of permits is issued with the intent to restrict discharges, the payment should be treated as a tax if the medium into which the water is discharged is not regarded as an asset in the SNA.

- If the discharge medium is an asset and the necessary conditions are met concerning the terms on which the discharge is permitted, then the payment for the permit should be treated in the same way as the payment for a licence to use the radio spectrum for mobile phones.

- If the ~~charge~~payment is linked to remedial action, ~~the payment is a payment for a service unless the amount levied is out of all proportion to the costs involved in subsequent water treatment in which case the payment should be then it is~~ treated as a tax.

27.66

## **N.F. Contracts for future production**

~~17.73~~27.86 Although human capital is not recognized as an asset in the SNA, there are cases where a contract that entitles the holder to limit the ability of a named individual to work for others may be regarded as an asset. The most prolific and lucrative contracts may be for sports players where, for example, a football club can “sell” a player to another. In fact they are not selling the person, they are selling the exclusive right to have that person work for them. Similar contracts exist for the rights to publish literary works or musical performances. All such contracts are treated as assets of the type entitlement to goods and services on an exclusive basis within the asset class of contracts, leases and licences.

~~17.74~~27.87 It is possible to imagine that similar contracts may exist for the production of goods in future. ~~An examination of~~For example, airlines may purchase the ~~practice of purchasing the options of~~option to buy future aircraft production ~~revealed, however, that in this case. However, if~~ there is no transferable asset and a change of mind on the part of the potential purchaser or failure to deliver on the part of the supplier is settled by a change in the arrangements between the two parties ~~and, it~~ does not lead to the sale of ~~the an~~ option to a third party. ~~If and hence no asset is created. Nonetheless, if~~ an instance arises where the option to purchase goods is treated in the same way as a contract for a named individual’s performance, the same ~~classification~~treatment would apply.

## **O.G. Leases as assets**

~~17.75~~27.88 As stated at the beginning of this ~~part~~chapter, contracts underlie many transactions recorded in the SNA and it is important to understand ~~what~~ the implications ~~are~~ for the time of recording and classification of transactions arising from a contract. It has been noted that permits or licences to use natural resources may constitute an asset as may permits to undertake specific activities and contracts for future production. There is one other condition that may lead to a contract being considered as an asset, which is another circumstance when the contract is transferable to a third party (that is, a unit other than the two specified in the original contract).

~~17.76~~27.89 Suppose a lease on an apartment agreed some time ago specifies the rental at 100 per month but if the same apartment were to be leased currently it would fetch 120 per month. From the lessor's point of view, the apartment is "encumbered" by the existing lease, that is, it carries a penalty (in this case of 20 per month) because of the existence of the lease. The encumbered value of the apartment is based on the present value of future rental payments taking the existence of the lease into account, that is, the future income stream is 100 for as long as the lease lasts and 120 thereafter (ignoring any allowance for inflation). The unencumbered value of the apartment is a present value based on an income stream of 120 per month from the current period forward. The value to be entered in the landlord's balance sheet is the encumbered value. If he wishes to sell the apartment and the existing tenant had the right to remain at the agreed rental, the encumbered value is all the landlord (lessor) could hope to realize. If he wished to realize the unencumbered value he would have to pay the tenant the difference between the unencumbered value and the encumbered value to be free of the lease. This amount, the encumbrance, can in some circumstances be treated as an asset of the tenant. The circumstances are that it is both legally possible and is practicable for the tenant to sublet the apartment to a third party. Because of the difficulty of identifying when such assets may exist, it is recommended that in practice these assets be recorded only when there is evidence that they have been realized.

~~17.77~~27.90 It is possible that the encumbered value of the apartment may be higher than the unencumbered value if rentals have fallen since the lease was agreed. In this case it is the landlord that benefits from the discrepancy between the contract price and the market price because the value of the apartment in ~~his~~the balance sheet is still the encumbered value. If the tenant wishes to cancel the lease, ~~he~~they may have to pay the landlord the difference between the encumbered value and the unencumbered value. Only in the exceptional case where the tenant pays a third party to assume the lease at the price specified in the lease, does this payment represent realizing an asset of negative value to the tenant. Once the lease expires or is cancelled, the value of the apartment returns to its unencumbered value.

~~17.78~~27.91 Assets reflecting such third-party property rights are always transitory. They exist only for the length of the lease and where there is a difference between the encumbered and unencumbered values. As each year passes, they reduce in value because the period during which the difference exists is reduced but may increase if the new rental price increases.

~~17.79~~27.92 The market price of the rental of an apartment is the price actually paid by the existing tenant. If, in this example, the original tenant remains in situ and pays 100 per month, this is the market price despite the fact that a new lease would fetch a rental of 120. Only if the original tenant sublets the apartment for 120 would the market price be recorded as 120. Of this, 100 will be paid to the landlord and 20 to the original tenant.

~~17.80~~27.93 The example above shows when a marketable operating lease may acquire a value as an asset. Permits to use natural resources and contracts for future production may also give rise to these sorts of third-party property rights assets. So may permits to undertake specific activities even though the original payment was treated as a tax if payable to government. Financial leases do not give rise to these sorts of assets. If the value of the asset being leased increases by more than the payments due under the financial lease, the lessee always has the option of selling the asset, repaying the loan and keeping the difference.

#### ~~27.67~~ Marketable operating leases as assets

~~17.81~~27.94 A marketable operating lease may be treated as an asset only when the two following conditions are satisfied:

- a. The lease specifies a predetermined price for the use of an asset that differs from the price the asset could be leased for at the current time, and
- b. The lessee is able legally and practically to realize this price difference by subcontracting the lease to a third party.

~~17.82~~27.95 In practice, it is recommended that such assets should be recorded only when the lessee does actually exercise ~~his~~their right to realize the price difference.

## **P.H. Other considerations**

## 1. Time-share arrangements

~~17.83~~27.96 One way of sharing an asset offering accommodation is by means of a “time-share” arrangement. The same expression, though, may be used for a number of different arrangements.

~~17.84~~27.97 One arrangement is similar to purchasing a house except that “ownership” is restricted to a particular period each year but in perpetuity. Exactly the same physical space is available to the owner each year. Another arrangement guarantees accommodation at a given time each year but not necessarily in the same physical space. Other arrangements consist of buying “points” in a scheme that the owner can use to purchase accommodation at different locations and times subject to availability.

~~17.85~~27.98 All time-share arrangements have a unit that is responsible for upkeep, maintenance, insurance and so on but there are variations in whether this unit is the ultimate owner of the complex and the subscribers are lessees or whether the unit acts as agent for the group of owners or subscribers. Similarly there are variations in whether the owner or subscriber may sell or bequeath ~~his~~their ownership to another unit permanently and whether they can sublet occasionally.

~~17.86~~27.99 The issue of whether participation in the time-share scheme gives rise to an asset will depend on the answers to these sorts of questions. If the owner has a nominated space, available in perpetuity, is eligible to act as part of the management committee for the scheme, can sell or bequeath the allocation at will, then the holding is most likely to be an asset of the same type as a house. If the owner has a fixed agreement to have some form of accommodation available at a given period for a fixed length of time, it is likely that this represents a prepaid lease but one that could be sublet occasionally or sold for the rest of the period of the lease as a transferable operating lease. A participant in a points-based scheme may have only an account receivable by way of an asset.

~~17.87~~27.100 Where time-share arrangements are significant, the conditions pertaining to them should be examined in the light of the general principles described in this ~~section~~chapter to determine how to record the transactions involved and classify the assets.

## ~~3.2.~~ Lost deposits

~~27.68~~27.101 Under any form of contract, it is possible that one party makes a payment and the other does not deliver the goods, services or assets promised in the contract. In many cases this gives rise to an account payable or receivable that the first party may reclaim from the second. In some circumstances this may not be possible. For example, cheap airline tickets are often offered on a non-refundable basis. The fact that prepayments are non-refundable is part of the business plan of the company concerned. Their output should be measured as the value of sales without reduction for the payments by clients who did not avail themselves of the services to which they were entitled. Volume measures of output will depend on the services actually delivered and the impact of the non-refundable deposits will show up as a price effect. It will also be reflected in the consumption expenditure figures of those paying for services they did not in the end take delivery of.

## Chapter 28: Non-financial corporations (revised title and revised content)

(OLD Chapter 21: Measuring corporate activity)

### A. Introduction

28.1 Non-financial corporations have long held an important role in the economy, but their role has shifted over time. For a long time non-financial corporations were the main organizational form for heavy industry such as manufacturing, mining, transport and utilities. Over time, their importance in producing services has grown, and the growth of digitalization has led to large non-financial corporations investing in software assets, databases and digital platforms. These changes have led to more investment in intellectual property products relative to traditional plant and equipment. Non-financial corporations have also become increasingly global, with growing importance to multinational enterprises, foreign direct investment, and outsourcing of production. This chapter discusses how these and other developments are reflected in the national accounts.

28.2 This chapter discusses aspects particular to corporations, many of which are common to both the financial and non-financial corporation sectors. Chapter 29 will focus on topics that are particular to financial corporations, but most of the issues discussed in this chapter are relevant to both financial and non-financial corporations, so reference will be made to corporations in general terms except for a few issues that are specific to non-financial corporations.

28.3 This chapter begins in section B by discussing the demography of corporations; how they come about, how they disappear and how they merge with one another. The consequences of these actions in the SNA are almost all to do with recording the acquisition of the owner's equity in corporations and in some cases reclassification of assets and liabilities between sectors. Section C looks at some subsectoring of non-financial corporations and how this can be effectively deployed for analysis. Section D considers the relationships between corporations in the domestic economy and in the rest of the world. Much of this section is concerned with aspects of globalization and the derivation of relevant indicators, topics which are covered in more detail in chapter 23. Section E recalls some of the discussion in chapter 17 and looks further at the contribution of assets to production. Section F looks at the consequences of financial distress and the implications of remedial action for recording within the SNA. The last section, section G, covers a rather different subject and looks at the emergence of commercial accounting standards such as the International Financial Reporting Standards (IFRS) and at the relationship between IFRS and the SNA.

**Commented [ED1]:** A new introductory paragraph to reflect the new title of the chapter and to make it parallel to the introductory paragraph in chapter 29.

**Commented [ED2]:** Explains that this chapter mostly discusses topics that are relevant for all corporations, both financial and non-financial.

#### 1. A note on terminology

28.4 As explained in section B of chapter 5, the term corporation is used in the SNA to cover a wide variety of legal forms of institutional units. In addition, the expression enterprise is used in connection with production activities. While corporation is normally the term of preference in the SNA, other documents, notably the *OECD Benchmark Definition of Foreign Direct Investment, fourth edition (Organisation for Economic Co-operation and Development, 2008)* referred to as the *BD*, tend to use enterprise in preference to corporation. Further, the register of all enterprises or corporations is usually called a business register, even though "business" is not a term commonly used in national accounts. In this chapter, all three terms are used without implying a difference between them.

### B. The demography of corporations

28.5 Maintaining a list of corporations is similar to maintaining a list of all individuals present in the country in that it is necessary to record new corporations as they come into being and to record those that cease to be. A business register normally serves an administrative function in keeping track of the existing businesses in the economy but also serves as the basic sampling frame for surveys directed at businesses. Thus it is normal

for a business register to contain information on the activity, size, location, etc. of each business and to note when the main activity of a corporation changes from one type of activity to another. In addition a business register may also include information on the links one corporation may have to other resident and non-resident corporations. [Best practices in the development and maintenance of business registers are presented in \*Guidelines on Statistical Business Registers\* \(United Nations, 2024\).](#)

## 1. The creation of corporations

[28.5](#)[28.6](#) Corporations can come into being in a number of ways. One is when what was previously an unincorporated enterprise within the household sector becomes incorporated. (The exact process of incorporation, such as when this may or must happen and how it is effected, will depend on the company law in effect in the country concerned.) When this happens, the assets and liabilities that were previously indistinguishably part of the household are separated off and become those of the corporation. In return for giving up control of these assets, and responsibility for the liabilities, the household acquires equity in the new corporation, initially exactly equal in value to the assets [less](#) liabilities transferred to the corporation. [This transaction is recorded in the financial account.](#) Once an enterprise is incorporated, the owning household no longer has a claim on the assets and has no responsibility for the liabilities but instead owns the equity in the corporation.

[28.6](#)[28.7](#) An individual may simply decide to set up a business, set up a legal entity and begin operations. Initially, there may be no assets of the entity and no liabilities but as these accrue they belong to the corporation and the owner's equity changes correspondingly. On a larger scale, there may be an agreement between a number of units, one or more of whom propose a business plan and one or more of whom agree to finance the operation. A formal agreement results in which the split of the rewards from the corporation's activity is determined and also the division of the responsibilities. The assets of the new corporation are recorded as being acquired by it and an amount of owner's equity in the corporation incurred as a liability towards the parties supplying the finance is also recorded.

[28.7](#)[28.8](#) It is not necessary for the corporation to issue shares for the agreement on the share of the profit arising from the activities of the corporation to be binding. Cooperatives and limited liability partnerships are two examples of units the SNA treats as corporations where the way in which profits are shared between the owners is clear even though there are formally no shares.

[28.8](#)[28.9](#) Corporations may also come into being at the initiative of government, an NPISH or a unit in another economy. In addition, a corporation may come into existence by the splitting of a previously existing corporation. This possibility is discussed below under mergers and acquisitions.

## 2. The dissolution of corporations

[28.9](#)[28.10](#) Similarly there are several ways in which corporations may go out of existence. The first is when an entity is wound up after having been declared bankrupt. (The exact process varies from country to country. In some countries a declaration of bankruptcy means the corporation must stop trading immediately and the process of winding up its affairs begins. In other countries, there may be a time lag while the corporation has an opportunity to continue trading while it tries to recover its position and only if this fails is it wound up.) When a corporation is wound up, the receiver (the unit responsible for administering the liquidation of the corporation) sells all of its assets and distributes the proceeds amongst those having a claim on the corporation in a legally predetermined order. The shareholders are [normally](#) the last to be allocated any proceeds. In the case where the corporation is bankrupt it is quite common that the shareholders receive nothing. Only in very exceptional circumstances will the shareholders have any responsibility to provide funds towards settling other liabilities of the corporation.

[28.10](#)[28.11](#) A corporation may be wound up voluntarily by its owners. When this happens the assets are sold and the proceeds are divided amongst the owners according to the shares each has in the corporation. If the corporation is one that had issued shares, it can only be wound up if a clear majority of shareholders agree or if a clear majority of the shares are first acquired by a sufficiently small number of units who can reach agreement to wind up the corporation.

[28.11](#)[28.12](#) The acquisition of all shares of a corporation need not be a preliminary to the corporation ceasing

to exist; it may simply continue with a smaller number of shareholders or even as a private unlisted corporation. The advantage of remaining incorporated is that there is a limit to the liability of the owners to meet any shortfall on the corporation's balance sheet. Thus even when an individual or group of individuals wants to control the whole of a corporation they may choose simply to make it an unlisted corporation but still one with the limited liability that comes with incorporation.

~~28.12~~<sup>28.13</sup> A third way in which a corporation may disappear is through it being merged with another corporation, though a merger does not automatically imply the merged corporation disappears. This too is discussed below under mergers and acquisitions.

### 3. Nationalization and privatization

~~28.13~~<sup>28.14</sup> The government may decide to take ownership of a corporation for a number of reasons, either because it is felt it is in the public interest for government to control the corporation, in response to financial distress or for other reasons. When this happens the ownership of the corporation passes to the government, that is the government acquires the equity in the corporation, but the assets of the corporation remain on its balance sheet unless the government decides to nationalize the corporation and disband it at the same time. Often but not always, government may make a payment to the previous owners of the corporation but this may not necessarily correspond to their view of a fair price. Unless the corporation is dissolved, the process of nationalization leads to a change in the ownership of the corporation from private units to the government but the assets and other liabilities of the corporation continue to be owned by the corporation. The sale or purchase of equity in the corporation is recorded as a transaction in the financial account. There is also a reclassification of the assets and liabilities of a corporation being nationalized from the national private subsector to the public subsector recorded in the other change in the volume of assets account.

~~28.14~~<sup>28.15</sup> The government may also decide to privatize a corporation it currently controls. When this happens the most usual mechanism is that its shares are offered to the public either for sale or, in some cases, without charge or perhaps at a price lower than the market would bear. When shares are offered free or at a reduced price, a capital transfer from government to the eventual shareholders needs to be recorded in the accounts as well as the acquisition of shares. As with nationalization, only the equity in the corporation changes hands, not its assets and other liabilities, and the change in ownership of the equity is recorded as a transaction in the financial account. The ownership of the assets and liabilities remains with the corporation but they are reclassified from the public to national private subsector in the other changes in the volume of assets and liabilities account.

~~28.15~~<sup>28.16</sup> There is more discussion on nationalization and privatization in chapter 30.

### 4. Mergers and acquisitions

~~28.16~~<sup>28.17</sup> The process of corporations merging and de-merging is of interest within an economy but especially interesting when the merger (or de-merger) involves units in different economies. Foreign direct investment can hardly be discussed without considering the subject of mergers and acquisitions. Some of the expressions commonly used in this field are listed below. The descriptions come from the BD but similar concepts appear also in the BPM<sup>7</sup>.

~~28.17~~<sup>28.18</sup> A merger refers to the combination of two or more corporations to share resources in order to achieve common objectives. A merger implies that, as a result of the operation, only one entity will survive and frequently occurs following an acquisition (described below). There are several types of merger possible.

- a. A *statutory merger* relates to the business combination where the merged (or target) corporation will cease to exist. The acquiring corporation will assume the assets and liabilities of the merged corporations. In most cases, the owners of merged corporations remain joint owners of the combined corporation.
- b. A *subsidiary merger* relates to an operation where the acquired corporation becomes a subsidiary of the parent corporation. In a reverse subsidiary merger, a subsidiary of the acquiring corporation will be merged into the target corporation.

- c. *Consolidation* is a type of merger which refers to a business combination whereby two or more corporations join to form an entirely new corporation. All corporations involved in the merger cease to exist and their shareholders become shareholders of the new corporation. The terms consolidation and merger are frequently used interchangeably. However, the distinction between the two is usually in reference to the size of the combining corporations. Consolidation relates to an operation where the combining corporations have similar sizes while merger generally implies significant differences.
- d. A *reverse merger* is a deal where the acquiring corporation ceases to exist and merges into the target corporation. If a corporation is eager to get public listing in a short period of time, it can buy a corporation with listed shares and merge into it in order to become a new corporation with tradeable shares.
- e. A *merger of equals* is a type of merger where the corporations involved are of similar size.

28.1828.19 An acquisition is a transaction between two parties based on terms established by the market where each corporation acts in its own interest. The acquiring corporation achieves control of the target corporation. The target corporation becomes either an associate or a subsidiary or part of a subsidiary of the acquiring corporation.

- a. A *takeover* is a form of acquisition where the acquiring corporation is much larger than the target corporation. The term is sometimes used to designate hostile transactions. However, mergers of equals (in size or belonging to the same sector of activity) may also result in a hostile takeover.
- b. A *reverse takeover* refers to an operation where the target corporation is bigger than the acquiring corporation.

28.1928.20 A divestment (de-merger) refers to the selling of the parts of the corporation due to various reasons:

- a. A subsidiary or part of the corporation may no longer be performing well in comparison to its competitors;
- b. A subsidiary or a part may be performing well but may not be well positioned within the industry to remain competitive and meet long-term objectives;
- c. Strategic priorities of the corporation to remain competitive may change over time and lead to divestments;
- d. Loss of managerial control or ineffective management;
- e. Too much diversification may create difficulties and thus lead the parent corporations to reduce the diversification of its activities;
- f. The parent corporation may have financial difficulties and may need to raise cash;
- g. Divestments may be realized as a defence against a hostile takeover.

28.2028.21 Corporate divestments can be conducted in different ways:

- a. A *corporate sell-off* is the sale of a subsidiary to buyers that are other corporations in most cases.
- b. A *corporate spin-off* occurs when the divested part of a corporation is floated on the stock exchange. The newly floated corporation is separately valued on the stock exchange and is an independent corporation. The shares in the newly listed corporation are distributed to the shareholders of the parent corporations who thereafter own shares in two corporations rather than one.
- c. An *equity carve out* is similar to a corporate spin-off but the parent retains the majority control. This form has the advantage of raising cash for the divestor.
- d. *Management buy-outs and buy-ins* occur when the buyer is the manager or a group of managers of

the corporation that is being sold off.

<sup>28.21</sup><sup>28.22</sup> In all these cases, transactions in the equity of the two corporations involved need to be recorded in the financial account and, possibly, a change of classification by sector in the other changes in the volume of assets and liabilities account.

## C. Subsectors

<sup>28.22</sup><sup>28.23</sup> The subsectoring of the non-financial corporations sectors is discussed in section D of chapter 5. There is a three-way split of corporations between those that are national private corporations, those that are controlled by the government (public corporations) and those that are foreign controlled. Within national private corporations and public corporations, “of which” items are included for domestically controlled public and private corporations that are part of a domestic multinational enterprise group (or “MNE” group, see paragraph 5.38). Furthermore, for countries where this is important, it is recommended to include within foreign-controlled corporations “of which” items for SPEs. In addition to these breakdowns according to ultimate control, it is also desirable to distinguish between market non-profit institutions (NPIs) and for-profit institutions (FPIs). The subsectors are shown in table 5.2 in chapter 5.

<sup>28.23</sup><sup>28.24</sup> The reason for identifying NPIs is twofold. In the first place, in order to have a comprehensive picture of NPIs, as described in chapter 31, it is necessary to be able to identify those market NPIs that are assigned to the corporations sector. Identifying them separately may be unexpected to some users, since there is often a misconception that all NPIs are non-market and fall in the NPISH sector. The other reason for identifying NPIs separately is that for some analyses it may be desirable to analyse corporations excluding the NPIs if it is felt that their economic behaviour is significantly different.

<sup>28.24</sup><sup>28.25</sup> In identifying publicly controlled corporations, there is a question about how to provide long time series if there has been a significant change in the number and type of corporations subject to public control during the period. It is usual to provide a time series that includes only those corporations that were subject to public control at each period in question. Because interest usually focuses on how much of the corporate sector was controlled by the government, and how this has changed over time, this gives an appropriate picture. However, if the intent is to explore the behaviour of the same group of corporations over time a supplementary table may be prepared that takes the current definition of publicly controlled corporations and uses this set of corporations over the time period considered regardless of whether or not they were publicly controlled for the whole of that period.

<sup>28.25</sup><sup>28.26</sup> Identifying foreign controlled corporations and domestically controlled corporations that are part of an MNE group is key to looking at the interaction between the domestic economy and the rest of the world. Chapter 23 discusses the role of MNEs and members of MNE groups in the economy and describes supplementary data that can be used for monitoring the activities of foreign controlled corporations and domestic MNEs. Exploring this in greater detail is the subject of the following section.

## D. Relations between corporations in different economies

<sup>28.26</sup><sup>28.27</sup> Deregulation of markets, technological innovations and cheaper communication tools have allowed investors to diversify their participation in competitive markets abroad. In consequence, a significant increase in cross-border financial movements including direct investment has become a key factor in international economic integration, more generally referred to as globalization.

<sup>28.27</sup><sup>28.28</sup> Regular analysis of direct investment trends and developments is an integral part of most macroeconomic and cross-border financial analysis. It is of prime importance to policy analysts to identify the source and destination of these investments. Several indicators based on direct investment statistics facilitate the measurement of the extent and impact of globalization.

## 1. Foreign direct investment

~~28.28~~~~28.29~~ Foreign direct investment (FDI) is a key feature of the [external accounts](#) and it is useful to review some of the basic concepts associated with this. Further details can be found in both BPM7 and the BD. In the context of FDI, the term enterprise tends to be used rather than corporation, but as noted in the introduction, no difference of meaning is intended.

~~28.29~~~~28.30~~ Direct investment statistics embody four distinct statistical accounts:

- a. Investment positions,
- b. Financial transactions,
- c. Associated income flows between enterprises that are related through a direct investment relationship, and
- d. Other changes in the value of assets [and liabilities](#), especially revaluation terms.

~~28.30~~~~28.31~~ Direct investment is a category of cross-border investment associated with a resident in one economy (the direct investor) having control or a significant degree of influence on the management of an enterprise (the direct investment enterprise) that is resident in another economy. [Ownership of 10 percent or more of the voting power is evidence of a direct investment relationship.](#)

~~28.31~~~~28.32~~ Direct investment may also allow the direct investor to gain access to the economy of the direct investment enterprise which it might otherwise be unable to do. The objectives of direct investors are different from those of portfolio investors who do not have significant influence on the management of the enterprise.

~~28.32~~~~28.33~~ Direct investment enterprises are corporations which may either be subsidiaries in which over 50 per cent of the voting power is held, or associates in which between 10 per cent and 50 per cent of the voting power is held or they may be quasi-corporations, such as branches, which are effectively 100 per cent owned by their respective parents. Enterprises that have no direct investment influence upon one another (that is the 10 per cent voting power criterion is not met) but are directly or indirectly influenced in the ownership hierarchy by the same enterprise (which must be a direct investor in at least one of them) are described as fellow enterprises.

~~28.33~~~~28.34~~ Direct investment relationships are identified according to the criteria of the Framework for Direct Investment Relationships (FDIR, described in the BD), including both direct and indirect relationships, through a chain of ownership. Suppose that corporation A controls corporation B and B controls C then A in effect has control over C also.

## 2. FDI and globalization

~~28.34~~~~28.35~~ Direct investment positions show an important class of investment made abroad and received from abroad, divided between equity and debt, at a given reference point in time. FDI positions as a percentage of GDP give one indication of the extent of globalization at that time. These structural indicators demonstrate the interdependence of economies.

~~28.35~~~~28.36~~ Financial transactions show the net inward and outward investments with assets (acquisitions less disposals or redemptions) and liabilities (incurrence less discharges) presented separately by instrument in any given period. FDI financial transactions expressed as a percentage of GDP provide one indicator of the changes over that period in the degree of globalization of an economy. This indicator provides early information on the relative attractiveness of economies (both domestic and foreign) for new investments after allowing for the withdrawal of investments or disinvestment during the same time period.

~~28.36~~~~28.37~~ Direct investment income provides information on the earnings of direct investors and of the direct investment enterprises. Direct investment earnings arise (i) from distributed earnings as well as undistributed earnings which are treated as reinvestment of earnings in that enterprise and (ii) from interest on inter-company loans, trade credit and other forms of debt. FDI income flows as a percentage of GDP provide information on the relative importance of the earnings of direct investment in both the reporting economy

and abroad.

### 3. The role of “pass through funds”

[28.37](#)[28.38](#) “Pass through funds” or “funds in transit” are funds that pass through a [direct investment](#) enterprise resident in one economy to an affiliate in another economy, so that the funds do not stay in the economy of the affiliate. Such flows have little impact on the economy they pass through. While special purpose entities, holding companies and financial institutions that serve other non-financial affiliates are particularly associated with funds in transit, other enterprises may also have pass through funds in direct investment flows.

[28.38](#)[28.39](#) Pass through funds are included in direct investment in standard presentations because they are an integral part of a direct investor’s financial transactions and positions with affiliated enterprises. (An exception is made for positions in debt instruments between related financial institutions.) Excluding these funds from direct investment would distort and substantially understate direct investment financial flows and positions at aggregate levels. Further, inclusion of these data in direct investment promotes symmetry and consistency among economies. However, for the economies through which the funds pass, it is useful to identify inflows and outflows not intended for use locally by the entity concerned.

[28.39](#)[28.40](#) FDI has a key role to play in development, especially in emerging countries. In order to explore how much of global FDI reaches these countries, and where it originates, a supplementary analysis is useful. Such an analysis identifies the country where the pass through funds originate by identifying the first unit other than a pass through fund in the host or investing economy (in the outward or inward chain) as appropriate.

### 4. Ultimate investing country

[28.40](#)[28.41](#) Presentations of FDI according to the *BD* show the country of the immediate counterparty and the industry of the immediate counterparty for outward FDI. For inward FDI, it is possible to determine not only the immediate counterparty but also the ultimate investor. The ultimate investor for this purpose is the enterprise that has control over the investment decision to have an FDI position in the direct investment enterprise. As such the ultimate investor controls the immediate direct investor. It is identified by proceeding up the immediate direct investors ownership chain through the controlling links (ownership of more than 50 per cent of the voting power) until an enterprise is reached that is not controlled by another enterprise. If there is no enterprise that controls the immediate direct investor, then the direct investor is effectively the ultimate investor in the direct investment enterprise.

[28.41](#)[28.42](#) The country in which the ultimate investor is resident is the ultimate investing country in the direct investment enterprise. It is possible that the ultimate investor is a resident of the same economy as the direct investment enterprise. (A controls B controls C. A and C are resident in the same economy but B is resident in another.) [This phenomenon is known as round tripping.](#)

[28.42](#)[28.43](#) In order to transform the usual presentation by country to the supplementary ultimate investing country presentation, the entire FDI position that is attributed to the country of residence of the immediate direct investor(s) is allocated to the country [of residence of the ultimate controlling parent.](#)

### 5. Multinational enterprises

[28.44](#) As well as information relating to [\(foreign\)](#) direct investment where only a 10 per cent voting power is required to identify a [\(foreign\)](#) direct investor, there is interest in analysing the activities of [members of MNEs](#) [groups](#), where [control is determined to exist through \(i\) an immediate \(foreign\) direct investment relationship where the direct investor owns more than 50 per cent of the voting power in the \(foreign\) direct investment corporation; or \(ii\) an indirect \(foreign\) direct investment relationship arising from the ownership of voting power in one direct investment corporation that owns voting power in another corporation\(s\) – indirectly through a chain of control \(see paragraphs \[5.126\]\(#\) to \[5.127\]\(#\)\).](#) Thus the [members of MNE groups](#) correspond to foreign controlled enterprises in the sense of subsectors in the SNA.

<sup>28.43</sup><sup>28.45</sup> If a domestically controlled public or private corporation is an MNE or is a member of an MNE group, i.e., it is either the ultimate controlling parent of one or more foreign corporations or it is controlled by a domestic MNE that is the ultimate controlling parent of one or more foreign corporations, then it should be classified as part of an “of which” subsector of corporations that are part of a domestic MNE (see paragraph 5.38). Section E of chapter 23 describes a template for institutional sector accounts and external accounts with additional granularity and SPEs (figure 23.6) which is designed to present details on foreign controlled corporations and domestically controlled public and private corporations that are part of domestic MNE groups.

<sup>28.46</sup> In addition to statistics on the activities of MNEs, statistics are also available for the wider group of corporations with links in other economies, not just those where there is majority ownership, called foreign affiliates. These statistics are known as Foreign Affiliates Statistics (FATS), and are described in [European Business Statistics Compilers’ Manual for Foreign Affiliate Statistics](#) (FATS) (Eurostat, 2024) and elaborated in *Measuring Globalisation: Handbook on Economic Globalisation Statistics* (Organisation for Economic Co-operation and Development, 2005). Work is continuing to ensure the consistency of the various sets of statistics cited in these and other publications on globalization.

<sup>28.44</sup><sup>28.47</sup> Another template for supplementary data presented in chapter 23 (table 23.2) identifies the role of enterprise characteristics in the current account. The template breaks down domestic versus foreign ultimate control and also calls for the identification of small and medium-sized enterprises. The chapter also suggests providing statistics on the Activities of Multinational Enterprises (AMNE statistics) and the closely related FATS. These statistics provide an additional perspective on the impact of foreign direct investment that is complementary to data on international flows and positions.

## 6. Outsourcing

<sup>28.45</sup><sup>28.48</sup> There are two ways in which a [non-financial](#) corporation A in economy X may have another [non-financial](#) corporation B in economy Y assemble parts for it. Although the effect appears similar, the consequences for recording in the accounts are quite different. Suppose that A and B are unrelated enterprises, and B contracts to do work for A in return for a fee. (This case is described elsewhere, for example in chapter 36.) In this case there is no recorded transfer of the items from A to B (or X to Y). Only the agreed fee is recorded as a transaction between the two economies.

<sup>28.46</sup><sup>28.49</sup> However, if A and B both belong to the same group of corporations, then it may be the case that there is a transfer of the risks and rewards of the items on their dispatch from A to B. The question is whether a realistic price is entered for the items in the trade figures for both A (and X) and B (and Y) as the items move internationally. When A and B are related, [transfer pricing is used to value the transactions between affiliated enterprises. In some cases the transfer prices may be distorted](#). Suppose the tax regime in Y is more liberal than that in X. It may then be the case that A artificially lowers the price of the items dispatched to B in order to minimize profits in X while B records a higher profit subject to the lower tax regime in Y. In principle, international accounting standards and the balance of payments recommendations indicate that items transferring across borders should be valued at “arm’s length” prices, that is to say prices that would prevail if there were no relationship between the two corporations involved. Making such an adjustment is not easy but it is in the interests of tax authorities, customs officials and the statistician to see whether appropriate adjustments can be made if the sums involved are significant and adjustments can be made with sufficient reliability. [Other aspects of global production are discussed in section B of chapter 23.](#)

## E. The contribution of assets to production

<sup>28.47</sup><sup>28.50</sup> Chapter 17 discusses the role of capital services in production and the calculation of multifactor productivity (MFP). The assets to be considered in calculating productivity are those fixed assets that are both owned and used by the enterprise plus any natural resources and other non-produced assets including contracts, leases and licences and possibly marketing assets they both own and use in production. Assets that are not legally owned by the enterprise but are subject to a financial lease are included in the calculations in the same way that they are recorded on the balance sheet of the enterprise. However, assets that are leased under an operating lease agreement are excluded. This may mean two enterprises undertaking similar

activities using similar assets may show different productivity figures because one uses assets it owns and the other assets that it leases. An area for supplementary analysis is to consider compiling information on assets according to the using rather than the owning industry and to look at the implications for operating surplus and productivity of the use of leased rather than owned assets.

## F. The consequences of financial distress

~~28.48~~~~28.51~~ Signs that a non-financial corporation is suffering financial distress include the level of profits that it has been generating recently and possibly the level of dividends it is able to offer. It is also probable that it suffers a cash flow problem and is unable to meet its liabilities on a timely basis. Competitors may take the opportunity to launch a takeover bid. However, if no takeover bid is offered the question here is how the corporation may survive at all.

~~28.49~~~~28.52~~ In a similar way, a financial corporation may suffer financial distress because it has difficulty in raising finance and is unable to service its liabilities. Again this is a circumstance in which a competitor may launch a takeover bid but this may not always be forthcoming.

~~28.50~~~~28.53~~ If the corporation, whether financial or non-financial, is deemed to be of national importance this may be an instance where government steps in and offers either to take over the corporation, in effect nationalizing it, or may offer a major capital injection in return for a degree of control, possibly full control, of the corporation. The recording of nationalization and capital injections by government as well as of the steps that may be taken under a bailout are discussed in chapter 30.

~~28.51~~~~28.54~~ Another possibility is that the government offers a guarantee to the creditors of the corporation in distress. The activation of a one-off guarantee is treated in the same way as a debt assumption. The original debt is liquidated and a new debt is created between the guarantor and the creditor. In most instances, the guarantor is deemed to make a capital transfer to the original debtor, unless the guarantor acquires an effective claim on the creditor, in which case it leads to the recognition of a financial asset (a liability of the debtor). The recording of guarantees including those offered by government is discussed in part B of chapter 25.

### 1. Bad debts

~~28.52~~~~28.55~~ All corporations, but especially financial corporations, may suffer from bad debts and this phenomenon may be particularly acute when other aspects of the economy also exert financial pressure on the corporation. Within the SNA, loans are always recorded as the amount that is due to be repaid to the creditor. In cases where the debtor has a bad credit rating this may overstate the market value of the loan. This is seldom done on a loan by loan basis but is regularly done for classes of loans.

~~28.53~~~~28.56~~ The SNA identifies a subset of bad debts as non-performing loans. As explained in paragraph 14.76, these are loans whose payments of interest or principal are past due by 90 days or more or interest payments equal to 90 days or more have been capitalized, refinanced, or delayed by agreement, or payments are less than 90 days overdue, but there are other good reasons (such as a debtor filing for bankruptcy) to doubt that payments will be made in full. The SNA recommends that memorandum items be compiled for the accounts showing the nominal and market value of bad loans and the implications for interest flows, the amount of interest accruing on the nominal value, the amount of interest outstanding from previous periods and the amount relating to the current period that is unpaid. The proposed memorandum items are discussed in paragraphs 14.77 to 14.78.

~~Elaborating the accounting for assets where the market value suddenly diverges from past trend values and the whole question of when it might be appropriate to define and use "fair values" is one item on the research agenda as explained in annex 4. In addition, circumstances emerging from the credit crisis that emerged in 2008 will continue to be monitored to see if other memorandum items or other steps should be recommended.~~

### 2. Debt rescheduling

28.5428.57 According to the accrual basis, repayments of debts are recorded when they are extinguished (such as when they are paid, or rescheduled, or forgiven by the creditor). When arrears occur, no transactions should be imputed, but the arrears should continue to be shown in the same instrument until the liability is extinguished. See paragraph 4.223 for more information.

## G. Links to International Financial Reporting Standards (IFRS)

28.5528.58 The *International Financial Reporting Standards* (IFRS) are a comprehensive set of accounting standards designed to apply to the general purpose financial statements and other financial reporting of profit-oriented entities.

28.5628.59 There is a close relationship between the SNA and IFRS. They are both accrual-based accounting standards and have similar measures of revenues, expenditures, assets and liabilities and similar accounting concepts of control, economic substance, recognition, and valuation. Compilation of macroeconomic statistics in accordance with the guidelines of the SNA is facilitated by the adoption of IFRS by profit-oriented entities.

28.5728.60 The SNA and IFRS have different objectives. The objective of general purpose financial statements is to provide financial information about the reporting entity that is useful to existing and potential investors, lenders and other creditors in making decisions relating to providing resources to the entity. The SNA is an integrated system of accounts covering the total economy and its five institutional sectors, two of which are the financial corporations and the non-financial corporations.

28.5828.61 This difference in objectives causes some differences in the information presented and in how accounting concepts are implemented. The main differences between IFRS and the SNA involve reporting entity, scope, consolidation, recognition of assets, recognition of liabilities, valuation, and the treatment of revaluations and other changes in volume. Table 28.1 summarizes the differences between SNA and IFRS.

**Commented [ED3]:** This section has been redrafted in response to Recommendation 7 of Guidance Note AI.1: “When it comes to valuation of transactions and positions in the SNA and BPM, it is also recommended to provide more details on the relationship between the SNA and BPM on the one hand, and business and public sector accounting standards on the other.”

**Table 28.1. Comparison of SNA and IFRS**

System of National Accounts	IFRS
<b>Objective</b>	
Allow users of macro-economic statistics to monitor and analyze the performance of the economy.	To provide financial information about the reporting entity that is useful to existing and potential investors, lenders and other creditors in making decisions relating to providing resources to the entity.
<b>Reporting entity</b>	
Institutional units and sectors: The statistical reporting unit is an institutional unit, defined as an entity that is capable, in its own right, of owning assets, incurring liabilities, and engaging in economic activities in its own name. However, the primary focus is on groups of institutional units (sectors or subsectors).	An entity that is required, or chooses, to prepare financial statements. A reporting entity can be a single entity or a portion of an entity or can comprise more than one entity. A reporting entity is not necessarily a legal entity.
<b>Scope</b>	
Total economy and the resident units comprised by its five institutional sectors. The general government sector includes government units at all levels of government, social security funds, and non-market producers controlled by government units.	Profit-oriented entities engaged in commercial, industrial, financial and similar activities, whether organized in corporate or in other forms.
<b>Consolidation</b>	
Flows between the units within a sector or subsector are generally not consolidated. Consolidated accounts are compiled for complementary or analytical presentations, including for the general	IFRS requires presentation of consolidated financial statements for the controlling entity. In this case, the reporting unit is the group, defined as the parent and its subsidiaries. Control is the main criterion that determines

System of National Accounts	IFRS
government sector.	consolidation.
<b>Recognition of assets</b>	
Based on economic ownership. The economic owner of a non-financial asset or financial asset is the institutional unit entitled to claim the benefits associated with the use of the asset by virtue of accepting the associated risks.	Based on control. Control of the resource entails the ability to use the economic resource and obtain the economic benefits that may flow from it.
<b>Recognition of liabilities</b>	
To maintain symmetric recording in the integrated framework of economic accounts, liabilities are only recognized when there is a recognizable corresponding claim of a counterparty. For example, provisions for one-off guarantees and bad debts are recognized in IPSAS but not in the main framework of economic accounts.	A liability is recognized whenever there is a present obligation of the entity to transfer economic resources as a result of past events. In IFRS, there is no need for a counterparty to recognize an asset for the reporting entity to recognize the liability.
<b>Valuation</b>	
Current market prices are used to value flows and stocks. Production cost, the market price of a similar item, the written-down current replacement cost or present value of future benefits may be used as alternative valuation methods if a market price is unavailable.	On initial recognition, IFRS requires measurement at transaction price. On subsequent measurement, historical cost, fair value, value in use, fulfilment value, or current cost can be used.
<b>Revaluations and other volume changes</b>	
Holding gains or losses are reported in the revaluation account, and changes in volume are reported and in the other changes in volume of assets and liabilities account.	Some gains or losses due to changes in prices or changes in volume of assets and liabilities are recognized in the Statement of Profit or Loss and some are recognized in the Statement Presenting Comprehensive Income.

28.5928.62 For multinational enterprises, the standard accounts may be available only for the group as a whole where relationships between enterprises in different countries have been consolidated. In this case, national accountants would need to consult other sources for the required non-consolidated data.

28.6028.63 Three particular areas where the IFRS adopts approaches somewhat different from the SNA are in the area of the recognition of holding gains and losses as income, in the recording of provisions and contingent liabilities, and in recording operating leases for lessees (where the IFRS has a treatment that is inconsistent between lessors and lessees). As discussed in paragraph 14.114, certain types of provisions should be recorded as supplementary items in SNA balance sheets. For operating leases with a term of more than 12 months, the IFRS requires the lessee to recognize an asset and associated liabilities, even though those assets and liabilities are also recognized by the lessor. The SNA treatment of operating leases is based on the concept of economic ownership and treats operating leases, regardless of duration, as not involving a change of economic ownership (see section B of chapter 27).

28.6128.64 In addition to the IFRS for private corporations, the International Public Sector Accounting Standards (IPSAS) perform a similar function for government bodies. There is a discussion of the IPSAS in chapter 30.

Commented [ED4]: GN WS.9 - recording of provisions

## Chapter 29: The financial corporations sector (S12)

### (NEW chapter)

#### A. Introduction

- 29.1 Financial corporations have taken on increased importance over the years, in many economies, reflecting both growth and diversification. Generally, the amount of funds channeled through the financial system has been on a long upward trend, reflecting financial innovation, as well as demographic trends and other factors. This has tended to promote the expansion of non-bank financial intermediaries, such as investment funds, insurance corporations and pension funds, and security and derivative dealers, central clearing counterparties and specialized financial intermediaries. Alongside these trends, the increased sophistication of financial activities and the interlinkages among types of financial corporations present the possibility of spillover effects in the event of financial disruptions originating in one subsector of the financial corporations' sector or from outside of the sector. The impact on the real economy of such events can be significant. The global financial crisis which began in 2007-08 underlined the need for improved and more detailed statistics on financial corporations alongside the need to better understand their sources and uses of funds.
- 29.2 There are many uses of financial corporations' detailed information, some of which are statistical and support national accounts' analysis and related data compilation. Other uses include monetary and financial sector analysis and studies of the financial system or specific sectoral activities. More recently, a key use of these data is financial stability analysis, sometimes requiring supplemental breakdowns of sectors or financial instruments, discussed later in this chapter.
- 29.3 This chapter discusses in detail the financial corporations' sector and its subsectors within the system of national accounts. The financial system is an essential element of most developed and developing economies, though its structure can vary across countries. For example, depository institutions may be dominant in certain economies. Non-bank financial intermediation, previously referred to as *shadow banking*, has taken on increased importance in other economies. In short, the size, complexity and the composition of the financial system may be quite different when looking across economies. Nevertheless, the components and measures of these systems are defined in a consistent way to promote data accuracy and international comparability of national accounts statistics.
- 29.4 This chapter is organized as follows. Section B provides an overview of financial corporations. ~~I and summarizes the impact of technology on the sector;~~ it also touches ~~upon domestic consolidation and nationality based on technology innovation and alternative organizational structures as supplementary~~ statistics. Section C discusses the activities of the various subsectors of financial corporations. Section D presents supplementary breakdowns on non-bank financial intermediaries, while section E discusses the links to Monetary and Financial Statistics. The material in this chapter dovetails with material in chapter 5 as well as section E of chapter 25. It also complements chapters 26 and 28.

#### B. Overview of financial corporations

##### 1. General concepts

- 29.5 As noted in Chapter 5, the financial corporations sector is made up of all resident corporations that are principally engaged in providing financial services ~~to other resident or non-resident institutional units,~~ including insurance and pension funding services, to other institutional units. It comprises all resident financial corporations regardless of the residence of their shareholders, the branches of non-resident corporations that are engaged in financial activity on the economic territory on a long-term basis, and all resident non-profit institutions that are market producers of financial services. Despite the use of the term corporations, the sector also includes investment funds and pension funds.

#### Definitions and sectoring

- 29.6 Financial intermediaries are institutional units that incur liabilities on their own account for the purpose of acquiring financial assets by engaging in financial transactions on the market. These include investment funds, insurance corporations and pension funds. Financial auxiliaries are institutional units principally engaged in serving financial markets, who do not take ownership of the financial assets and liabilities they handle. For captive financial corporations most of their assets or liabilities are generally not available on open financial markets.
- 29.7 The SNA uses a detailed breakdown of financial corporations. Financial corporations are allocated to subsectors of the financial corporations sector based on their primary principal activities, considering and sometimes adjusting for regulatory data constraints in different jurisdictions. The nine “core” subsectors of financial corporations are the central bank, deposit-taking corporations except the central bank, money market funds (MMF), non-MMF investment funds, other financial intermediaries except insurance corporations and pension funds, financial auxiliaries, captive financial institutions and moneylenders, insurance corporations, and pension funds.

### **Domestically based statistics**

- 29.8 As is the case for all institutional units, financial corporations are only compiled for units which are resident in the country; for more details on the residence of institutional units, see chapter 5. This groups together a set of institutional units, which allows for a proper calculation of SNA measures such as output, value added/GDP, earned income/GNI, saving, domestic investment, financial flows and balance sheets, and is fully consistent with the external accounts (balance of payments and international investment position). Regardless of whether the universe for any given subsector is comprised of a combination of legal entities, or some higher level of consolidation for complex enterprises (often referred to as statistical enterprises), or some combination of the two, the statistics are based on the principle of residence.
- 29.9 Some subsectors of the financial corporations sector can be dominated by large institutional units, often complex corporations. In the case of complex corporations, it is possible that some domestic subsidiaries are consolidated, although legal entities often coincide with the concept of an institutional unit. Where there is some degree of consolidation, these institutional units are classified to the subsectors based on their primary activities.
- 29.10 Many of the larger financial institutions are multinational enterprise groups (MNE groups) with operations and affiliates/subsidiaries in more than one economic territory. In other words, they own one or more foreign corporations/entities (either as majority owned or wholly owned subsidiaries), but in the case of these foreign controlled corporations the accounting is limited to the financial relationships, be it equity investments or loans, including related income, in the non-resident affiliated or non-affiliated corporations. Similarly, for foreign controlled corporations operating in the national economy, only the domestically consolidated financial statements of the resident subsidiary entities are relevant for the SNA.

### **Production and the nature of financial services**

- 29.11 The production of financial services is the result of financial intermediation (which includes financial risk management and liquidity and maturity transformation, and insurance) or auxiliary financial activities. Financial corporations do not account for a large share of economic production in most economies. The nature of the services offered by financial corporations varies by subsector, and in some jurisdictions (depending on regulations) certain financial corporations may offer more than one type of service. An example of this would be a bank also offering investment services, taking advantage of the retail banking system of local branches. The production of financial services is the result of financial intermediation (which includes financial risk management and liquidity and maturity transformation), insurance, or auxiliary financial activities.
- 29.12 As implied in paragraph 29.6, the composition of assets and liabilities in the subsectors of financial corporations reflect their financial activities and, hence, may affect the measures of output in these subsectors. Financial services may be paid for explicitly or implicitly, and some transactions in financial assets involve both explicit and implicit charges. Both explicit and implicit service charges are common across a number

of subsectors. For example, deposit-taking corporations (except the central bank) charge fees but most of their output is measured as implicit financial services on loans and deposits, as described in chapter 7. As another example, financial auxiliaries' output is often comprised of explicit service charges.

- 29.13 Financial services are produced almost exclusively by financial corporations because of the usually stringent supervision of the provision of these services. Similarly financial institutions rarely offer non-financial services. There are a few exceptions. For example, for a retailer offering credit facilities to its customers (e.g., financing consumer goods). However, in such cases the credit is usually provided by a subsidiary which is classified in the financial corporations sector. Financial corporations may also create subsidiaries dealing with particular forms of financial services. For example, a credit card operation may be associated with a particular bank but may be institutionally separate.
- 29.14 There are three broad types of financial activities: the services of financial intermediaries, the services of financial auxiliaries, and other financial services. **Financial intermediation** involves financial risk management as well as maturity and liquidity transformation, where the institutional units incur financial liabilities (accepting deposits or issuing bills, bonds or other securities) or uses own funds to acquire mainly financial assets (making loans and advances, or purchasing bills, bonds or other securities). This includes insurance corporations and pension funds which invest assets on behalf of their policyholders and contributors. The output of these services is calculated in different ways. **Auxiliary financial services** facilitate financial intermediation by acting on behalf of others at no risk to themselves. **Other financial services** are provided by financial corporations; institutional units providing financial services, where most of their assets and liabilities are not available on open financial markets (e.g., captive financial institutions).
- 29.15 There are ~~four~~ **five** main ways in which financial services are provided and charged for. Three of these are discussed below, while financial services associated the central bank are described in chapter 7 and financial services associated with insurance and pension schemes are discussed in chapter 24. A more detailed discussion of output measures can be found in chapter 7 as well as in the UN-ECB *Financial production, flows and stocks in the system of national accounts*.

### *Explicit financial service charges*

- 29.16 Many services come under this heading and may be provided by different subsectors of financial corporations. Financial intermediaries typically charge explicit fees for services (and some also charge for implicit services). *Deposit taking corporations* may explicitly charge for arranging loans, or explicitly charge for services related to deposits; explicit charges may also exist for other services. Other types of financial intermediaries also charge various explicit fees, as follows. Investors in *investment funds* may be confronted with different fee structures, which can include one-time sales charge (front-end load commission), ongoing charges, transactions costs and account fees. Even though these service charges may be paid by the investment funds and subsequently charged, implicitly or explicitly, to the investors, all services related to investment funds are considered to be directly charged to the investors; see paragraphs 7.176 to 7.178. *Securitization corporations* charge fees that cover administrative charges and default risk, either as a fixed amount or percentage of the asset value being securitized. *Underwriters' security and derivative dealers* can charge a variety of fixed or transactional based fees and commissions. *Lending and leasing corporations* typically charge fees on the origination of loans and leases, as well as any penalties for late payment. *Central clearing counterparties* "clearing charge" is paid by traders to settle transactions in securities through the agency. Factoring firms also charge fees, typically as the discount on the accounts receivables purchased.
- 29.17 *Captive financial institutions and moneylenders* may also charge various types of fees for their services, although output may also be calculated as the sum of costs for certain institutional units.
- 29.18 Fees and other charges associated with *insurance corporations* and *pension funds* are discussed in chapters 7 and 24.
- 29.19 Financial auxiliaries charge fees for their varied services. For example, *flotation corporations* may charge other corporations to arrange the issue of shares. *Foreign exchange bureaux* may charge a foreign transaction fee as well as a currency conversion fee. ~~Supervisory authorities may charge membership fees.~~ *Institutional investment managers* charge management fees against the funds (usually as a percentage of the assets) that

they manage on behalf of their various clients. Notably, *head offices of financial corporations* may charge fees, or their output may be calculated as sum of costs.

*Implicit financial services provided in association with interest charges on loans and deposits*

- 29.20 **Deposit taking corporations (except the central bank)** primarily accept deposits and extend loans. This activity provides a mechanism which allows the depositor to lend to the borrower. Each of the two parties pays an implicit fee to the bank for the intermediation service provided. The implicit services are measured using a reference rate. The difference between the interest rate paid to banks by borrowers and the reference rate plus the difference between the reference rate and the interest rate actually paid to depositors is used to calculate charges for the **implicit financial services on loans and deposits**. The reference rate applies to both interest paid on loans and interest paid on deposits so that the amounts of interest recorded as such in the SNA are calculated as the reference rate times the level of loans and deposits in question. The difference between these amounts and the amounts actually paid to the financial institution are recorded as output of financial intermediaries and uses of financial services by the borrowers or depositors. Refer to paragraphs 7.163-7.169 for further discussion.
- 29.21 A number of deposits and loans embed charges for implicit financial services on loans and deposits. The **types of deposits** include transferable deposits and other deposits, which typically include saving deposits, fixed term deposits, non-negotiable certificates of deposit; deposits of limited transferability, and overnight and very short-term repurchase agreements if they are considered part of the definition of broad money or if they concern agreements between deposit-taking corporations; shares of other similar evidence of deposits issued by savings and loan associations, building societies, credit unions and the like; and repayable margins in cash, related to financial derivative contracts. The **types of loans** cover amounts overdrawn on overdrafts, installment loans, hire-purchase credit, revolving credit, mortgage loans, and loans to finance trade credit; securities repurchase agreements (except those included in broad money or those between deposit-taking corporations) and gold swaps; and financing in the form of a financial lease.
- 29.22 **Financial intermediaries other than deposit-taking corporations** can also generate implicit financial services by offering loan facilities. Consumer or business lending corporations, financial subsidiaries of retailers or financial corporations that specialize in leasing (e.g., property companies, aircraft leasing companies) as well as moneylenders' loans from own funds or from funds received from a sponsor are examples of financial institutions that make loans without accepting deposits.
- 29.23 Some other points are worth noting relating to implicit financial services on loans and deposits. Liquidity transformation services should remain [asa](#) part of these services, but estimates should be closely scrutinized during periods of volatile movements in reference rates; and a single temporal reference rate should be used to estimate the relevant services. The choice of reference rate should be determined by national circumstances with the reference rate based on (a) a single observable exogenous rate (e.g., interbank lending rates), or (b) a reference rate based on a weighted average of observable exogenous rates of maturities with different terms (weighted by the stock of loans and deposits in each maturity), or (c) a weighted average of the endogenous interest rates on loans and deposits. Credit default risk should, in principle, be excluded from implicit financial services on loans and deposits but this is typically not the case. Therefore, any countries that can manage to make this adjustment are encouraged to compile unadjusted supplementary measures for international comparability. For international trade in implicit financial services, different currencies may be involved. As a consequence, the relevant services charges should be calculated by at least two groups of currencies (national and foreign currency) with (ideally) separate reference rates applied for each currency (see para 7.185 for additional details). No ~~such~~[implicit financial](#) services [on loans and deposits](#) are calculated for central banks.
- 29.24 Lastly, implicit financial services on loans and deposits ~~give rise to counterpart adjustments. The total of these financial services~~ must be allocated to user sectors by applying either a “bottom-up” approach or a “top-down” approach. The former approach is used when the compilers have access to counterpart data, such that SNA interest and the related implicit service charges can be accurately allocated. The latter approach is used when such information is not available, as a consequence of which compilers have to distribute SNA interest and the implicit service charges using a variety of indicators. It may be that both approaches are

combined if counterpart data are partial. In both instances, compilers will have to make a distinction between implicit service charges that should be recorded as intermediate consumption and service charges that affect final consumption of sectors, by referencing the underlying deposits and loans as either corresponding to corporations, households as consumers or to households as producers (owners of unincorporated enterprises and other self-employed persons) or dwelling owners.

### *Financial services associated with the acquisition and disposal of traded securities and currencies*

- 29.25 These financial services are basically estimated margins between buying and selling prices. Refer to paragraphs 7.189-7.194 as well as paragraphs 25.xxx-25.xxx for further discussion.

## **2. Technological innovation**

- 29.26 Technology-enabled innovation in financial services, generally referred to as *Fintech*, is a relatively new trend in the financial system. Fintech often simply refers to new ways of providing financial products, technologies, and access modes to products already available on the market. These can have a material effect on the provision of financial services in the subsectors of financial corporations, resulting from new business models, applications, and processes. It can also result in new products. Fintech is not linked to specific institutional (sub)sectors and could be used across institutional sectors.
- 29.27 Financial intermediation platforms, for example, facilitate financial transactions, such as payment, funding or other transactions. They receive fees or commission for their financial services. These new financial services fall within existing categories of products and new digital assets also typically fall within existing asset categories.
- 29.28 Entities that are involved in Fintech do not constitute a separate institutional (sub)sector. However, statisticians are encouraged to compile further supplementary (*of which*) breakdowns for subsectors, if the impacts of this financial innovation are considered significant and if this activity can be separately identified. If the entity providing a specialized financial platform is a separate institutional unit it has legal status, then they would be classified as a separate statistical unit within financial auxiliaries (S126). This can be the case with crowd funding platforms and peer-to-peer lending platforms.
- 29.29 A similar approach is recommended for the external accounts. This topic is discussed comprehensively in chapter 22.

## **3. Alternative organizational structures as supplementary statistics**

### **Financial corporations by control**

- 29.30 The extent of MNE groups in the financial corporations sector continues to expand and can be significant for certain subsectors in many economies. This applies to foreign and domestically controlled institutional units. For the analysis and an improved understanding of the national financial system, it is also important to distinguish financial corporations which are controlled by government or other public units. For these reasons, it is recommended to break down the financial corporations' sector, to show foreign-controlled corporations as well as corporations that are part of a domestic MNE group, in addition to publicly controlled corporations. More specifically, the following subsectors based on control are recommended:
- Public financial corporations
    - Of which: part of a domestic multinational corporation/enterprise group
  - National private financial corporations
    - Of which: part of a domestic multinational corporation

- Foreign-controlled financial corporations
  - Of which: Special Purpose Entities (SPEs)

### **Nationality-based statistics**

- 29.31 Many national non-financial and financial corporations have large foreign investments in either foreign securities and other financial instruments, and/or hold significant equity investments abroad through majority or wholly owned foreign subsidiaries (outward direct investment positions in the external accounts). Both types of investments expose them to a variety of risks, but the nature of the investment and the risk is different, and more extensive, for direct investment. Where the domestic direct investor has controlling interest in foreign subsidiaries, it is fair to say that the risks are only partly measured in the national financial accounts and balance sheets, and in the external accounts (including the coordinated portfolio investment survey and the foreign direct investment statistics). This identifies an important data gap with respect to financial stability concerns.
- 29.32 The financial accounting of corporations allows for consolidation of majority owned or wholly owned foreign subsidiaries in the parent enterprise. However, this global consolidation for multinational financial corporations is inappropriate for most macroeconomic statistical uses (as explained above). At the same time, there is increasing interest in worldwide consolidated data for these MNE groups, especially for systemically large corporations. Therefore, for a more thorough understanding of corporate risks across economies it is useful to look at MNE groups, both in an aggregated form and by individual MNE group. Such statistics from a so-called “nationality perspective” put emphasis on international inter-corporate ownership and control in corporate groups as well as geographical counterpart relationships and can shed light on various types of potential vulnerabilities.
- 29.33 The “nationality perspective” was pioneered by the Bank of International Settlements (BIS), which made use of both domestic and globally consolidated banking data to better understand the global banking system as well as national banks’ exposures. In addition to providing a global picture of balance sheets, it also allows for a more detailed analysis of counterpart country information or geographical exposure of balance sheets. This helps in gaining a broader understanding of the supply of credit, both domestic and foreign sourced; the uses of funds; funding risks associated with currency exposures and maturity risk (i.e., mismatches between assets and liabilities); and country credit risk.
- 29.34 Given the large number of non-depository financial MNE groups with significant national and global operations, combined with the need for enhanced financial stability monitoring, a case can be made to extend the nationality approach beyond deposit-taking corporations to the other financial corporations’ subsectors. Such efforts can help enhance the measurement of risk.
- 29.35 In this context, it is useful to consider two generic cases of corporate group exposures.
- The domestic MNE group (say, in country A) faces risks with respect to its own assets and liabilities, which include its foreign investment abroad. However, a simple analysis of their direct investment positions can mask the total exposure of the parent firm. In the case of foreign-controlled enterprises (say, in country B), the domestic parent’s risk may extend to the foreign subsidiaries’ assets, in terms of earning power and valuation; and to its liabilities, relative to liquidity concerns, interest costs, leverage as well as market risk, credit risk, exchange rate fluctuation risks. The foreign subsidiaries are the immediate debtors, but the domestic parent corporation is usually ultimately responsible for this debt (by explicitly or implicitly guaranteeing such debt). In this sense, cross-border connectivity is more complex than the parent’s foreign investment claim. And, under certain financial instability circumstances, when this connectivity impacts the domestic parent, it can also feedback to the domestic parent’s economy.
  - A further dimension to this can extend beyond the domestic parent if, in turn, this enterprise is ultimately owned by another foreign corporation. In other words, the domestic parent in country A owns a foreign affiliate in country B, but a corporation in country C ultimately owns the corporation in country A. This implies that the corporation in country A is the intermediate controlling parent and the corporation in

- country C is the ultimate controlling parent. In order to better understand the inter-corporate ownership exposures in the national economy (in this case, country A), it is useful to stratify the domestic parents of foreign controlled affiliates into (a) ultimate parents and (b) intermediate parents (where the ultimate parent is in another country). In this sense, one can view nationality measures for corporations as two separate levels of commitments with different degrees of exposure. This also reinforces the usefulness of the foreign direct investment concept of ultimate controlling parent.
- 29.36 Nationality-based statistics are relatively new in the context of macroeconomic statistics, less so in the context of reporting for supervisory and regulatory purposes. But, by combining existing country data sources and/or leveraging additional information (e.g., additional survey, administrative records, or financial supervisory reports) or using newer techniques such as record linkage, it is possible to work towards developing such measures. For example, large MNE groups have financial reports on a globally consolidated basis. Compilers have financial reports for resident units of these same firms for the purpose of compiling national accounts and other macroeconomic statistics. *Foreign direct investment statistics* also exist for these same entities, with geographical details. In addition, many countries publish various statistics (income, assets and liabilities, employment, etc.) for MNE groups, as part of *Foreign affiliate statistics* and/or *Activities of multinational enterprises*. Underlying all these sources of information are data on individual companies. What is required is an ability to cross-reference datasets, and to generate a methodology for nationality-based estimates that can ensure international comparability.

## C. Financial corporations' subsectors

- 29.37 Financial corporations are engaged in a wide range of financial activities. They are grouped together in institutional subsectors largely according to their dominant activities, following the primary activity criterion to classify units. That said many financial corporations in one subsector may offer similar types of financial services as those in other subsectors. For example, deposit-taking corporations make loans as do select financial intermediaries in other subsectors. Another example is that a securities dealer financial intermediary can also undertake brokerage activities similar to a financial auxiliary. However, often this does not affect sub-sectoring, as financial corporations may have unconsolidated subsidiaries undertaking the various activities. This section highlights the main functions of each type of financial corporation in each of the subsectors to help compilers delineate different types of financial corporations.

### 1. Central bank (S121)

#### Definition and functions

- 29.38 The central bank is the financial institution (or institutions) that exercises control over key aspects of the financial system. Their principal functions generally include: conducting monetary policy, including by issuing currency and regulating money supply and credit; managing international reserves and the payments system; promoting financial stability, including regulation and macroprudential supervision; and acting as a banker to the government.
- 29.39 The following financial intermediaries are classified to this subsector.
- The national central bank, including where it is part of a system of central banks, which in most economies are separately identifiable institutions that are subject to a varying degrees of government control, engage in ~~different~~<sup>differing</sup> sets of activities, and are designated by various names (e.g., central bank, reserve bank, national bank, or state bank).
  - Currency boards or independent currency authorities that issue national currency which is fully backed by foreign exchange reserves.
  - Central monetary agencies of essentially public origin (agencies that manage foreign exchange or issue banknotes and coins that maintain a complete set of accounts but are not part of central government).
  - Supervisory authorities that are not separate institutional units and are part of the central bank. If they constitute separate institutional units, then these units and their accounts are part of *Financial auxiliaries*.

- National agencies, including notional resident units, of centralized currency unions.

- 29.40 As long as the central bank is a separate institutional unit, it is always allocated to the financial corporations' sector even if it is primarily a non-market producer. Many central banks regulate and/or supervise other deposit-taking corporations and sometimes also other financial corporations, and these activities are included in the central bank subsector. However, if such activities are performed by a separate institutional unit (or units) that are affiliated with government or other sectors and if they are mainly engaged in regulating or supervising financial units, they are classified as financial auxiliaries.
- 29.41 A few economies do not have central banks. Any central banking activities that are performed by the government and cannot be separated into specific institutional units are consolidated with general government.
- 29.42 In economies in which some central [banking activities](#) are performed wholly or partly outside the central bank, particularly holding reserve assets, consideration should be given to compiling supplementary data for the monetary authorities.
- 29.43 The existence of a currency union central bank (common currency and single monetary policy) does not preclude the existence of country central bank institutional units within the union. However, the residence of the currency union central bank is the region to which the union applies.

~~29.44 Some central banks may also engage in commercial banking, as a secondary activity.~~

~~29.45~~29.44 Monetary policy is exercised through a variety of means, including: interest rate policy, typically by setting the central bank's main policy rate (e.g., refinancing operation, overnight lending rate), thus influencing short-term markets; open market operations by buying and selling financial instruments, mainly government debt instruments; refinancing banks through repurchase agreements; and exchange rate policy; altering bank reserve requirements; and forward guidance and other communication activities. In many jurisdictions central banks also have a financial stability analysis function, monitoring the financial positions (e.g., liquidity, leverage, capital adequacy) of large financial institutions as well as the financial risks and vulnerabilities and the economy more generally.

~~29.46~~29.45 Some central banks may also engage in commercial banking, as a secondary activity.

## 2. Deposit-taking corporations except the central bank (S122)

~~29.47~~29.46 Deposit-taking corporations, except the central bank, have financial intermediation as their principal activity. To this end, they have liabilities, principally in the form of deposits or other financial instruments (such as short-term certificates of deposit) that are close substitutes for deposits. The liquid liabilities of deposit-taking corporations are typically included in measures of money broadly defined. These liabilities are the source of funds for the credit extended primarily in the form of a variety of types of loans. This constitutes the fundamental line of business for the financial intermediaries in this subsector. The major investment income receivable and payable reported by these institutions is interest. However, the structure of this subsector can differ across jurisdictions, sometimes with a significant public corporations' presence. The following financial intermediaries are classified in this subsector.

~~29.48~~29.47 **Banks** (sometimes referred to as commercial banks) include a wide variety of institutions and functions which can, along with the size and concentration of the banking industry, differ across economies. Some banks are primarily retail banks, with the bulk of their deposit-taking and lending activities as well as other services focused on households. Other banks, such as all-purpose banks, offer a range of services to a broad set of clients. For example, commercial banks offer both loans to business and consumers in their lending activity. Universal banks offer a multitude of different services. In addition to the loans and deposits business, they can provide a variety of investment services including asset management, investment advisory services, services related to securities transactions, underwriting and financial analysis. Some of these banks have evolved over the years, expanding their business line through mergers and acquisitions, and can also offer non-traditional services such as investment funds as well as insurance from non-consolidated units which are typically classified in other institutional (sub)sectors. The branch banking system offers a convenient front door to these additional services.

~~29.49~~29.48 It is also possible that some merchant banks (which specialize in financing international trade and focus on large corporate clients) may also be included in this subsector, given that they raise funds through deposits or their close substitutes. However, if their sources of finance are shares and debentures, they would be largely classified in other financial intermediaries except insurance corporations and pension funds (S125).

~~29.50~~29.49 This subsector also includes institutions sometimes referred to as **near-banks**, or quasi-banks. These are deposit-taking corporations that operate similarly to banks, sometimes under different legislation. These entities are often smaller in size and typically focus more on the core business of deposits and loans, the latter sometimes related to specialized financing. These include savings banks that tend to operate more like retail banks, with a focus on interest-bearing deposits and long-term investments such as home financing. Mortgage loan companies and other lenders that accept deposits as a principal source of funds are also covered in this group. In some jurisdictions, banks have acquired and consolidated savings banks. Savings and loan associations (sometimes referred to as credit unions) are a type of cooperative savings bank that is typically owned (and overseen) by its retail customers. The customers are members of the association that each hold a nominal share in the organization, typically a small portion of the initial deposit. Also included are building societies, which are cooperatives similarly owned by their members and mainly offer mortgage financing.

~~29.51~~29.50 Near-banks also encompass more specific types of deposit-taking corporations, such as agricultural credit banks and rural credit banks. The former can be large financial institutions, sometimes organized as cooperatives. In some economies, these banks are public corporations.

~~29.52~~29.51 This subsector also includes any other specialized banks or other financial corporations which take deposits or issue close substitutes for deposits, such as municipal or regional-provincial credit institutions, post banks, post office giro institutions (any of which may be public corporations), giro banks and other electronic money institutions.

### 3. Money market funds (MMFs) (S123)

~~29.53~~29.52 Investment funds are collective investment schemes that are split into two subsectors within the financial corporations sector. The first of these are **Money market funds** (MMFs) which issue shares or units to the public. As the name suggests, the proceeds are invested primarily in money market instruments such as short-term debt securities of government, commercial paper, promissory notes, repurchase agreements on short-term government securities, bankers' acceptances and short-term certificates of deposit and various types of bank deposits. As a result, MMF shares or units are viewed as close substitutes for deposits and are segregated from other investment funds. ~~Investment~~ Any open-ended investment trusts, unit trusts and other collective investments schemes with the same characteristics are grouped in the subsector.

~~29.54~~29.53 MMFs are open-ended funds (see below). They are considered low-risk investments that are highly liquid. MMF shares or units can be transferred by cheque or other means of direct third-party payment. Investors can choose differently comprised portfolios of MMFs in which to invest (e.g., a Treasury fund).

### 4. Non-MMF investment funds (S124)

~~29.55~~29.54 In most economies the second and larger component of investment funds is **Non-MMF investment funds**. Funds invested in these investment funds are not close substitutes for deposits and are not transferable in the same way as MMFs. These collective investment schemes can be specialized funds, focused on specific types of investments (e.g., debt securities, equities, investments tied to real estate) tailored to investors' needs. These investments can evolve over time, adapting to the funds' portfolio strategy or market conditions. Broad types of specialized funds include:

- Equity funds, which buy stocks from some combination of publicly traded companies. Some funds may be designed to provide a steady stream of dividend income (income funds), while others are focused more on holding gains (growth or accumulation funds). There are also private equity funds which focus on investing in unlisted companies. Closely associated with equity funds are index funds that are based on a pre-set basket of stocks or index.

- Fixed income or bond funds, which can acquire combinations of the debt securities of corporations and governments.
- Real estate investment funds, which specialize in debt (including mortgages) and equity of companies that purchase real estate. These are sometimes also referred to as real estate investment trusts, but this subsector notably excludes any such similarly termed domestic non-financial corporations set up as trusts, or similar types of funds, which hold real estate as their major asset. In the case of hybrid real estate funds, these would be classified according to the principal activity (i.e., share of value added) and, as such, most of these funds would likely not be included in the financial corporations sector. Mortgage real estate trusts providing mortgage finance or other real estate loans, or purchase mortgage-backed securities, are also included among real estate investment funds.
- Hedge funds are heterogeneous schemes, with high minimum investments ~~balanced with light regulation and a wide range of~~ *with relatively unconstrained and wide ranging* investment ~~and/or financing~~ strategies in liquid assets (e.g., short selling, derivatives) *in order to maximize absolute returns*. This degree of liquidity means that they are usually set up as open-ended funds, although there may be time restrictions on redemptions
- Mixed/balanced funds with a wide variety of investments – stocks, bonds and other investments (including crypto funds and credit funds). Balanced funds offer a combination of safety, income and holding gains. Some such funds stick to a rigid allocation of stocks and fixed income instruments. For other funds the mix is more flexible. Mixed funds should not hold more than 50% of their assets in one type of investment.
- Investment funds investing in other funds (funds of funds). These comprise fettered funds which only invest in funds that are administered by the same management company, and unfettered funds which invest in any fund (including those managed by competing companies). A case can be made for consolidation of fettered funds and individual funds administered by the same management company, though this is not typical because the latter may have shareholders other than funds of funds.

## General characteristics of investment funds

~~29.56~~29.55 Essentially, MMFs and non-MMF investment funds ~~sell~~*issue* shares or units in the fund (see chapter 5 for a general discussion of trusts) *and invest predominantly in financial assets*. As such, they are separate institutional units with multiple investors/beneficiaries and a complete set of financial records. Management and administration of the funds may be provided internally but are usually outsourced to specialized units. Fund managers may be separate institutional units classified in financial auxiliaries or part of the secondary activities business of other financial institutions such as banks or other deposit-taking corporations.

~~29.57~~29.56 It may also be the case that investment funds are set up and/or owned by another institutional unit, such as a pension scheme. In some countries, pension funds may have outsourced part of their investments to a fully owned investment vehicle with a separate legal status and autonomy of decision.

~~29.58~~29.57 Investment funds can be set up as either *open-ended* or *closed-ended*. Open-ended funds allow for buying and selling on a regular basis, such that the investment is liquid. The shares or units are, at the request of the holders, repurchased or redeemed directly or indirectly out of the undertaking's assets. These funds issue new shares to match investors' demand and retire shares as investors redeem. The shares of open-ended funds can be traded on an exchange (exchange-traded funds) or be unlisted sold directly to investors. At the same time, holders can remain invested in the fund indefinitely. Open-ended funds are sometimes referred to as mutual funds.

~~29.59~~29.58 Closed-ended funds only apply to non-MMF investment funds. They have defined maturity periods and investors can be locked in during the maturity period, such that the investment is comparatively less liquid. They issue a limited number of shares that are open for subscription only during a specified period, and new shares or units are rarely issued once the fund has been launched. Thereafter investors can only acquire new shares on the secondary market, either directly or on an exchange (if listed) or sold directly to investors. Private equity funds and private real estate investment funds are examples of closed-end funds. Some personal trusts can also be included here if there are multiple investors/beneficiaries. Otherwise, when

the trust is restricted to a strictly limited number of beneficiaries, they would be included under captive financial institutions (see the discussion of trusts in paragraphs 5.103-5.111).

## 5. Other financial intermediaries, except insurance corporations and pension funds (S125)

~~29.60~~29.59 As the name suggests, this subsector contains a heterogeneous group of financial intermediaries which raise funds on financial markets (other than deposits or their close substitutes) for the acquisition of various types of assets.

~~29.61~~29.60 *Financial corporations engaged in the securitization of assets* are special purpose units/vehicles, set up as either trusts or tax-exempt companies with the purpose of pooling loan assets (consumer debt, mortgages, business credit, etc.) and issue marketable asset-backed securities to investors. They are typically set up by the originators or lenders (e.g., a bank) to move segments of assets off their balance sheets and/or to shift their portfolios toward securities with higher liquidity as well ~~asa~~ manage risk. Even though the assets are transferred to the special purpose unit/vehicle, the lenders may still administer all aspects of the loans, and the debtors may be unaware of the securitization. The securitization corporations offer asset-backed and mortgage-backed securities with attractive rates of return to a broad range of investors, which can include the lenders themselves. Securitization activity may also include structured securitization (related to alternative funding formats) and synthetic securitization (related to credit risk)

~~29.62~~29.61 *Underwriters, security and derivative dealers* (operating on own account) are financial corporations (which can include some investment banks activity, see 29.66) that engage in the business of dealing in securities and other financial instruments on their own account. These units are often both dealers and brokers in a transaction, buying and selling from the firm's own inventory of securities. They are financed initially with equity, and typically raise the funds to finance their investments through various means. This can include the returns from secured financing such as collateralized loans to their clients (e.g., repurchase agreements) or securities lending arrangements or from investment strategies (e.g., the proceeds from returns on short positions financing long positions). They may also rely on commercial paper to raise funds. These corporations often also provide portfolio management or investment advising services.

~~29.63~~29.62 *Corporations engaged in lending or leasing* cover a variety of types of financial institutions. These include the (non-consolidated) sales finance subsidiaries and associates of various retailers such as those involved in the household goods and automobile financing and leasing industries, personal financing corporations (e.g., consumer loan companies), and other companies offering various types of commercial financing and/or leasing. This subsector also includes credit card companies and buy now/pay later service providers. Entities such as "buy now pay later service providers" might be included here, if they are institutional units and financial corporations.

~~29.64~~29.63 *Central clearing counterparties* provide clearing and settlement transactions in securities, derivatives and repurchase agreements markets. Clearing relates to identifying the obligations of both parties to a transaction, while settling is the exchange of the securities, derivatives and repurchase agreements and the corresponding payments. The central clearing counterparties involve themselves in transactions as principals (often trading on own account or assuming a counterparty position). They are, effectively, the seller to all buyers and the buyer to all sellers. They mitigate counterparty risk using tools like margin requirements and the practice of monitoring of member firms' creditworthiness. If central clearing counterparties do not act as principals to the counterparties, then they would be considered as corporations that facilitate financial transactions and would be included in financial auxiliaries (with exchanges and settlement institutions).

~~29.65~~29.64 *Bank re-structuring agencies* that support strategies to liquidate, recapitalize or merge banks as well as the recovery of bank assets, where the main risks and rewards are with the entity, and not another entity. This activity usually takes place under situations of bank financial distress.

~~29.66~~29.65 *Specialized financial corporations* that provide various types of financing cover a wide range of

financial corporations that also constitute financial intermediaries.

- Factoring firms purchase accounts receivable from a business (improving that business' liquidity) by paying the amount due less fees - usually reflected in as a discount from the face value of the receivable, although it is possible that explicit fees are charged as well. Factoring has largely replaced trade bills (i.e., discounted bills of exchange with banks). The factoring firm assumes all (non-recourse factoring) or part (recourse factoring) of the risk of downpayment. The difference between the two types is related to the size of the discount, although there is no difference in the conceptual treatment of these contracts. Factoring constitutes a loan to the debtor (purchaser). Output is typically estimated by the discount offered to the supplier without adjustment for possible credit losses. No corresponding implicit financial services on loans are accounted for, factoring being somewhat different from traditional intermediation. However, in situations of high inflation or increased risk of credit defaults, the full discount may not result in an appropriate measure of output, and a discount adjusted for these factors may provide a more appropriate measure of output.
- Firms that facilitate corporate reorganizations (primarily investment banks), including mergers and acquisitions, by providing short-term financing as required. Investment banks assist corporations in raising funds in equity and debt markets and provide strategic advisory services for mergers, acquisitions, and other types of financial transactions. They also invest their own funds, including in the securities of their clients as well as in hedge funds dedicated to investing in corporations. Investment banks do not usually have deposit liabilities that meet the definition of broad money.
- Firms involved in import/export finance (which can include public corporations).
- Venture capital and development capital firms that provide financial support to start-ups and other businesses with the potential for rapid and significant growth, as well as other venture capital initiatives. These firms usually raise funds from investments by a limited group of partners.

## 6. Financial auxiliaries (S126)

29.6729.66 Financial auxiliaries constitute a wide-ranging group of corporations engaged in activities associated with or supporting financial transactions and markets or with providing the regulatory context for these transactions. These types of institutional units do not take ownership of the financial instruments being transacted. Corporations facilitating financial transactions, such as central clearing counterparties, stock exchanges, derivative exchanges, and repurchase agreement settlement institutions are financial intermediaries if they generally act as principals to the counterparties to the underlying transactions; otherwise, they are classified as financial auxiliaries. [The majority of financial auxiliaries generate their income from fees and commissions.](#)

29.6829.67 Various types of brokers are classified to this subsector. **Loan brokers** match borrowers and financial institutions engaged in lending. They try to secure favourable loan options and financing rates on behalf of their clients who are seeking funds. In some economies they are actively involved in promoting real estate financing. **Securities brokers** arrange for the purchase or sales of stocks, bonds, and other securities. They can also advise customers regarding financial investments, such that they are grouped with other financial advisory services. However, unlike investment dealers, they do not acquire securities on their own account. **Insurance brokers** are independent consultants working with multiple insurance companies on behalf of clients seeking insurance or clients that are already policyholders. Salvage and claims adjusters and insurance and pension consultants perform functions that support the insurance and pension business.

29.69 **Central supervisory authorities** of financial intermediaries and/or of financial markets are part of this subsector, but only if they are separate institutional units. The supervisor of financial institutions is typically one (or more than one) public corporation(s) that regulate financial institutions, protecting depositors, policyholders, pension plan members and others, with the purpose of promoting a sound and efficient financial system. **Securities and exchange boards or commissions** are generally public corporations that enforce the laws governing securities and derivatives markets. In some economies selected supervisory functions are consolidated within the central bank or part of a government ministry, in which case it is not a separate institutional unit and excluded from this subsector.

29.69 Corporations that support financial markets and transactions in different ways are also classified to this subsector:

- **Foreign exchange bureaus**, or currency exchanges, allow customers to exchange one currency for another. To be included in this subsector they must constitute separate institutional units, that are independent corporations outside of financial corporations that offer similar services, such as banks.
- **Stock exchange companies** provide trading in listed shares, but many also offer trading services in other financial instruments such as marketable debt securities and exchange-traded derivatives. In some economies exchanges are more specialized to financial instruments.
- **Crypto asset exchanges, trading platforms and other platforms** allow users to buy, sell, and stake (i.e., lend) crypto assets for a fee or commission.
- **Insurance exchanges** are insurance-related businesses that are set up to allow customers to exchange insurance contracts, thereby spreading the risks associated with those contracts amongst participants.
- **Flotation corporations** are firms that manage the issue of securities, including initial public offerings.
- **Corporations that arrange derivative instruments** such as swaps, options and futures (**without issuing them**) can be included here, if not consolidated with financial corporations in other subsectors.
- **Corporations that guarantee bills and similar instruments** are also classified to this subsector, if not included elsewhere. For example, transferable bills of exchange, which are commonly used in international trade and provide benefits, make the guarantor the third party to the arrangement.
- **Credit rating agencies** assess the creditworthiness of an issuer of debt securities with regard to its financial obligations. They evaluate the issuer's overall financial capacity and willingness to make scheduled payments on a specific issue. They are classified as financial auxiliaries.
- **Corporations that provide infrastructure for financial markets** exist to ensure that customers (businesses and governments) can make and receive payments securely and efficiently. This covers securities depository companies, custodians, clearing offices that facilitate transactions without acting as a counterparty and nominee companies holding investments for others. This also includes paying for and delivering securities and other financial instruments. It is worth noting that banks and other financial intermediaries are also involved in payments systems, such that the financial infrastructure is interconnected.
- **Corporations primarily involved in the operation of electronic payment systems** (including online payment systems and mobile payments platforms) that do not incur liabilities against the activities in the underlying instruments.
- **Peer-to-Peer (P2P) lending companies and marketplace lending platforms** (often referred to as crowd funding) may also be included here. These entities facilitate lending of money from individuals and other lenders, often unsecured loans, to unrelated individuals or small businesses thus circumventing traditional financial intermediaries. The loans are for relatively small amounts and made mostly to individuals for consumption or credit refinancing. They operate online by matching individual investors and other lenders with borrowers but assume no liability or potential risk associated with the loans, and the main source of income is the fees collected from borrowers and lenders (if in the rare instance own funds are used for lending, then they would be classified as units in S125).

29.70 **Institutional investment managers** are also included in this subsector. These are firms that manage pension funds, investment funds [where their main activity is not financial intermediation](#), other funds associated with companies, as well as private funds (which can include estate, trusts and agency accounts). They are responsible for the implementing of a fund's investment strategy and overseeing its trading activities but do not hold the assets. In many economies, the assets under their management are relatively large.

29.71 Three other types of institutional units are included in this subsector. The first is the **head offices of financial corporations** which are principally engaged in controlling financial corporations, or groups of financial

corporations. These corporations do not undertake the intermediation business of those financial corporations. Some head offices may be consolidated with the financial corporations that they control and would, therefore, not be institutional units to be classified in this subsector. The second is **resident head offices of foreign banks**, if they do not accept deposits or extend credit on their own account. The third is **non-profit institutions** that are independent legal entities serving financial institutions. This would include foundations set up by financial corporations.

## 7. Captive financial institutions and money lenders (S127)

29.72 Institutional units that provide financial intermediation services, but where their assets and most liabilities are not transacted in open financial markets are classified to this subsector. These corporations transact with a limited group, such as subsidiaries, or subsidiaries under the same holding corporation, or entities that make loans from their own funds provided by one sponsor.

29.73 Different corporate structures give rise to entities with a variety of functions, as included in this subsector:

- **Holding companies** are legal entities that hold only the assets (owning controlling levels of equity) of a group of subsidiary corporations and whose principal activity is owning the group without providing any other service to the enterprises in which the equity is held; that is, they do not administer or manage other units. They typically receive income (mostly dividends) from their holdings. They are sometimes referred to as “parent companies”, given their ownership of subsidiaries. ~~They may also hold intellectual property rights, for purposes of centralized management over these assets and/or as a means to safeguard these assets from potential claims against operating companies.~~ Holding companies can be domestically or foreign owned. Often holding companies are set up for mergers and acquisitions activity.
- **Special purpose units** are legal entities (usually a corporation) that are set up for specific and/or temporary purposes, such as raising funds in open markets to be used by their corporate parent company. The specific purpose might be to finance a large project or complex equity financing deals, while insulating the principal firm from any associated risks. These units are usually set up to obtain specific advantages to the global enterprise provided by the host jurisdiction, such as tax lowering strategies. They are usually foreign owned (i.e., non-resident parent) and are directly or indirectly controlled by non-residents, in which case they are known as special purpose entities (SPEs). Similarly, *brass plate companies* are legal entities that lack any connection to the jurisdiction of incorporation – that is, set up in a foreign country with an office and no material operations. They typically only hold liquid assets unless they are shell companies with no assets and are also often associated with tax lowering strategies. Shell companies can be set up prior to cross-border corporate acquisitions or to provide access to a parent financial company to financial markets abroad. Special purpose units included here exclude securitization vehicles that qualify as separate institutional units and are to be classified as other financial intermediaries.
- **Conduits, intragroup financiers and treasury functions** when these functions are taken on by a separate institutional unit. Conduits (often SPEs) typically refer to entities that raise funds, which could be in the form of debt securities, shares, or partnership interest on open financial markets for other affiliated corporations or for various types of public projects. Often the conduit’s liabilities are guaranteed by the parent company or government.

29.74 Various types of lenders that provide loans through own funds or through a sponsor are classified to this subsector. **Moneylenders** are lenders that can undertake different functions, including making loans, providing cheque-cashing services, money orders, etc. Loans are often at relatively higher rates of interest. **Pawn shops** are a type of used merchandise store that provide financing to clients in return for holding an asset for a specified period of time as collateral. They can also make unsecured loans. **Captive specialized lending institutions** provide loans from funds received from a sponsor, such as a government unit or an NPISH. They can be involved in various types of lending such as student loans, farm loans, import/export loans (possibly including some factoring), etc. These entities can include public corporations.

29.75 **Sovereign wealth funds** (SWFs) are included here if they actively manage their portfolios and provide financial services on a market basis to the general government; otherwise, they are part of the general government sector, unless the unit is a resident of another economy. An SWF is created and owned by the

general government to hold, manage or administer assets (including foreign investments) to achieve financial objectives. The funds can originate from various sources, including privatization proceeds, fiscal surpluses and receipts from natural resources, etc.

- 29.76 **Trusts and similar wealth holding entities** that solely hold assets and liabilities (along with the associated property income) for a restricted group of investors or beneficiaries. In the case of a single beneficiary or investor, the accumulated assets should be assigned to the sector of the beneficiary or investor, unless this unit is resident to another economy than its beneficiary or investor. *Estates, trusts and agency accounts/funds* (ETAs) mainly include various types of personal trusts for a restricted group of beneficiaries (see chapter 5 for a general discussion of trusts). In these cases, the restricted group of beneficiaries assumes the risks and rewards. It also includes similar accounts/funds in case a single beneficiary who assumes the risks and rewards is resident in another country. These can include inheritance trusts, trust funds for children, family trusts related to an ongoing incorporated or unincorporated business (e.g., a farm). The fund managers, or trustees, of these units are typically covered in financial auxiliaries, and are not subject to the risks and rewards of the fund. In practice, however, ETAs may be included in elsewhere; given that they are often relatively small, it may be common that some of the funds are derived residually as part of the household sector. In terms of those that can be measured, these would mostly be larger funds. In the case of one beneficiary (sometimes also the trustee in the case of a bare trust), the fund is consolidated with the investor/beneficiary and allocated to the household sector. In the case of a number of beneficiaries assuming the risks and rewards, then the fund is included under closed-end non-MMF investment funds.

## **8. Insurance corporations (S128)**

- 29.77 The insurance corporations subsector consists of financial intermediaries that offer various forms of insurance to individual institutional units or groups of units. Reinsurance (insurance contracts between insurance companies) is used to manage the risk associated with large, unexpected, claims. These corporations are either called insurance or assurance companies. Some types of insurance companies are more specialized in the products that they offer, and some are general insurers. Independent insurance agents (that sell products for any insurance company) are not part of this subsector, but rather are included in financial auxiliaries. For a full discussion of insurance corporations, refer to chapter 24.

## **9. Pension funds (S129)**

- 29.78 This subsector consists of social insurance pension funds that are institutional units separate from the units that created them. As such, these units are *autonomous pension schemes* with invested assets (funded plans), that are geared to provide income in retirement as well as other benefits (e.g., death benefits) principally for specific groups of employees and self-employed, including persons temporarily without employment. These pension funds are often organized as trusts (referred to as trustee pension plans) and they exist because of legislation and/or regulatory framework. They would typically have a board of trustees that oversees the fund. Pension funds can either be defined benefit or defined contribution type of schemes, depending on how the retirement benefits are determined. For a full discussion of pension funds, refer to chapter 24.

# **D. Non-bank financial intermediation and supplementary instrument details**

## **1. Background**

- 29.79 In most economies the banking industry is well regulated and typically governed by legislation. Deposits can have reserve requirements with the central bank (against client deposits), they may be subject to withdrawal requirements by type of account, and they may also be protected (deposit guarantee schemes). The types of loans banks can make may also be subject to restriction in some jurisdictions. Certain types of other investments may also be limited, such as with derivative trading. Banks may also have to follow certain accounting and supervisory requirements, such as those related to having specific provisions for loan losses and general provisions on losses on other financial assets. As a result, the financial stability risks associated

with banks are reasonably well understood and monitored.

- 29.80 This is not necessarily the case across the diverse group of other financial intermediaries involved in a variety of credit intermediation in the subsectors of financial corporations. For non-bank financial intermediation (NBFIs), there are varying degrees of oversight across these subsectors, which can differ from economy to economy. Therefore, it is fair to say that the financial stability risks are less well understood for NBFIs, while at the same time increasing amounts of funds are flowing through these entities. Moreover, many NBFIs may be loosely associated with banks and other financial intermediaries making them more vulnerable to systemic risk.
- 29.81 The global financial crisis that began in 2007-08 has led to an increased interest in developments within the financial world, particularly non-bank financial intermediation (colloquially referred to as “shadow banking”) and its impact on economic/financial risk as well as sustainability. As this activity has expanded in many economies, it has provided an alternative to bank funding. However, as the financial crisis revealed, it can also present a source of risk to financial stability.
- 29.82 Non-bank financial intermediaries ([which comprise subsectors S123, S124, S125, S127, S128 and S129](#)) are discussed in section C above. This section focusses on additional details that can provide a deeper understanding of their activities. The statistical community responded on how to better capture non-bank financial intermediation (NBFIs) in macro-economic statistics as part of the G20 Data Gaps Initiative (DGI), specifically, recommendation II.5 of DGI-II. It was acknowledged that the standard breakdowns of the financial corporations sector as well as the standard breakdown of financial instruments in the sequence of economic accounts may not be sufficient to identify associated risks within non-bank financial intermediaries. It was therefore recommended to introduce additional supplementary subsector and instrument details. Without these additional details, in the economies where relevant, much of the relevant parts of this activity would remain “in the shadows”.

## 2. Further institutional sector breakdowns in the SNA

- 29.83 As is evident from section C, there are various types of financial institutions within the subsectors of financial corporations. Therefore, following the financial crisis, DGI-II concluded that more granular breakdowns within the financial corporations’ subsectors are important to more clearly distinguish the groups of institutional units involved in non-bank financial intermediation. The purpose is to provide more insight into the possible build-up of financial risk and related spill-over effects from a macroeconomic perspective.
- 29.84 These supplementary details constitute more significant elements, typically in economies with a more developed financial system. Therefore, they principally apply to jurisdictions where the activities of certain NBFIs are significant. This includes further breakdowns of the following financial subsectors.

### Money market funds (MMFs) (S123)

- 29.85 Money market funds (MMFs) are highly liquid, and tend to be quite engaged in credit intermediation, liquidity transformation and maturity transformation. They are vulnerable to liquidity risk (liable for a run), interest risk, as well as vulnerable to credit problems. There are two basic types of funds for which a supplementary split is recommended; and even though the difference is likely not large, this split can provide some further insight into the systemic risk of MMFs.
- **Constant net asset value funds**, as the name suggests, aim to maintain a constant value. These are accounted for at amortized cost. This approach values the assets at amortized cost. This amounts to purchase price plus/minus the discount/premium linearly over the life of the asset. However, these funds are subject [to](#) potential losses and increases in operating costs.
  - **Variable net asset value funds** allow for fluctuation in values and are accounted for at market prices. In this case, the assets are valued at the prices at which they could be sold in the period, and the share price of such funds can fluctuate and are subject to market risk.

## Non-MMF Investment Funds (S124)

- 29.86 Most non-MMF investment funds shares are open-ended, but closed-ended funds also exist and can vary in size across economies. Therefore, given that these broad types of funds face different risks, and that they have grown rapidly in many economies, this is the high-level supplementary split of this subsector.
- ***Open-ended funds*** are highly liquid and offer frequent redemptions as noted in Section B above. In other words, shares of the funds can be purchased and sold frequently. There is no limit on the number of shares that can be issued in such funds, and they can be purchased through a broker or directly from the fund. At the same time, these funds tend to focus on longer term assets which may not be liquid. This maturity mismatch vulnerability between assets and liabilities can become problematic during times of market stress. Market risk is also a factor.
  - ***Closed-ended funds*** are traded on an exchange but are less liquid and face market risk and may also face credit risk. Investors entering or leaving the market must buy or sell existing shares.
- 29.87 Further, within each type of fund, the risks can vary. Equity funds face quite different risks than bond funds which face different risks than real estate funds or hedge funds. As a result, it is recommended that the supplementary subsector information also include, for both open-ended and closed-ended funds, the following breakdowns to have an enhanced picture of the investment fund industry structure for select economies as well as a more complete sense of potential vulnerabilities in this subsector:
- ***Real estate funds;***
  - ***Equity funds;***
  - ***Bond funds;***
  - ***Mixed or balanced funds;***
  - ***Hedge funds; and,***
  - ***Other funds***

## Other Financial Intermediaries, except insurance corporations and pension funds (S125)

- 29.88 This subsector has a variety of financial institutions, with each facing different risks, such as credit, market and maturity mismatch risks. As such, it is recommended that the following supplementary or “of which” subsector details be made available to users.
- ***Financial corporations engaged in the securitisation of assets.*** Various types of credit instruments are routinely converted to securities and sold to investors. Credit cards have a different risk profile to mortgage loans and, overall, investors know little about the quality of the [individual](#) assets being securitized. Securitization activity can be associated with various risks, including credit and liquidity risks, but also possibly reputational, transaction, compliance, and legal risk. As a result, it is important to produce supplementary statistical information on these vehicles for economies for which this activity is significant. This will allow SNA users access to [information on](#) the securitized assets as well as the short-term and long-term asset-backed securities.
  - ***Financial corporations engaged in lending and leasing*** cover a variety of types of lending from the financing arm of retail companies, consumer and other personal loans, various types of commercial financing and leasing, as well as financing via credit cards. In some economies, the funds advanced by these companies are relatively large, such that their balance sheet composition is of interest in terms of credit risk and potential maturity mismatches, since often their external sources of funds are short-term.
  - ***Underwriters, security and derivative dealers*** are corporations that engage in the business of dealing in securities and riskier financial instruments on their own account and face market risk and counterparty risk, among other risks. As noted above in Section C, their sources of funding are specialized. Therefore, in countries with well-developed financial systems their activities can be substantial, and therefore their SNA assets and liabilities are of keen interest in relation to financial stability.

- **Specialised financial corporations** that provide various types of financing cover a wide range of financial corporations and activities including factoring, investment banking, international trade finance and venture capital, each with risks attached. Growth can be sporadic for some components and steady for others, while each uses different sources of funding. The activities of these special type of financing entities may be significant in certain economies, such that their SNA assets and liabilities are of interest for financial stability purposes.
- **Central clearing counterparties.** These provide clearing and settlement transactions in securities, derivatives and repurchase agreements markets, often assuming a counterparty position. As a result, these intermediaries can face a number of potential risks, including counterparty credit risk, liquidity risks, settlement bank risk, custody risk, investment risk, and operational risk (e.g., IT systems risk). Since the global financial crisis, their activity has grown as the share of centrally cleared transactions has expanded. Therefore, their SNA accounts are of interest for financial stability purposes.

## Captive financial institutions and money lenders (S127)

29.89 The financial activities and therefore the risks are quite different across the group of financial intermediaries in this subsector. As a result, supplementary breakdowns of the following units are useful for better understanding and monitoring these types of entities, especially in the case of large cross-border transactions and positions.

- **Trusts, estate and agency accounts (ETAs)** are captive financial institutions that hold assets and liabilities on behalf of a party/parties and for the benefit of another party/parties than itself (beneficiary/beneficiaries). (For a discussion on when trusts and similar arrangements are to be considered as separate institutional units see paragraphs 5.103 – 5.111.) The beneficiaries of ETAs bear the risk in these arrangements, and there can be a fair bit of private wealth in these types of units in certain countries. Given that there are no restrictions on investments, fund performance depends partly on the decisions of the fund managers and on the developments in various markets in which assets are invested. In this sense, it would be ideal to have some explicit statistics on ETAs, especially in economies where these types of funds are prevalent, and holdings are significant.
- **Corporate groups' captive financial entities** are institutional units created by a financial or non-financial non-resident or resident corporate group to fulfil specific financial activities, other than insurance, for the sponsor. The directors of corporate captive typically have limited or no discretionary powers; activities are strictly defined by the terms of the entity contract or arrangement. A corporate captive is often, though not exclusively, a satellite company of another entity and forms an ancillary part of the associate entity's business by warehousing particular assets or risks. This group includes entities such as financing conduits, holding companies, intra group lending companies, and captive factoring and invoicing companies. Of particular note are (Foreign-owned) SPE-type captives/foreign owned SPEs captives. These entities have generated a lot of interest in recent years, reflecting both their growth as well as a need to better understand their purposes. Little is known about their operations, which can range from raising funds on behalf of a foreign parent to being part of a tax minimization strategy for a global corporation, such that supplementary data could prove beneficial.
- **Other captive finance companies and moneylenders** includes entities that provide financial services exclusively with own funds or funds provided by a sponsor to a range of clients, and incur the financial risk of the debtor defaulting. These types ~~of money lenders~~ entities are often seen as lenders of last resort. As such, they typically charge higher rates of interest than other lenders, sometimes much higher. Therefore, it is useful to have separate data on these types of lending units, as a means of understanding financial fragilities in other sectors, especially the household sector. Increased recourse to these types of lenders sheds light on growing financial fragility in certain segments of the economy.

## Insurance corporations (S128)

29.90 As noted in Section C, insurance corporations tend to be significant in many economies. However, they have different lines of business with different risk profiles. Therefore, to better understand potential vulnerabilities

in the two broad lines of business - non-life insurance (including reinsurance) and life insurance - separate supplementary SNA financial data are recommended for the following.

- **Non-life insurance corporations.** Non-life insurance and similar products tend to face relatively more uncertainty ~~that than~~ does life insurance. Non-life insurance faces financial performance risk on its investment portfolio (reserves to meet claims) and inflationary risk ~~the risk of associated with inflation~~ which can erode the asset base and increase the costs of claims. However, the main risk to non-life insurance arises from the inability to accurately estimate future claims and expenses and therefore to properly set the premiums for such insurance risk. This is one of the reasons for the existence of re-insurance contracts among insurance companies to help spread this risk. While it may be possible to estimate the “rough likelihood” of say fire damage claims on insured property, this is not the case if these are triggered by any sort of natural disasters such as wildfires, and earthquakes. Natural disasters, operator’s incompetence, and intentional damage all randomly affect the fluctuation and size of claims. To compensate for this vulnerability insurance companies usually sell supplementary insurance (or charge higher premiums to insert specific clauses in insurance contracts) related to such potential occurrences.
- **Life insurance corporations.** Life insurance claims involve a lower degree of uncertainty than ~~do~~ non-life insurance claims. Future life insurance claims are relatively more straightforward to estimate by making use of statistical tools (e.g., morbidity tables, life expectancy and retirement by cohort groups, etc.) which makes for generally lower insurance risk. As a result, and with future payments generally known, life insurance and its products primarily face financial investment performance risk. The main issues evolve around whether investments are sound and whether markets continue to generate sufficient returns to meet current and future claims. In this regard, inflation is also a risk which can reduce the value of their portfolio holdings and the income generated by these assets.

## Pension funds (S129)

29.91 Pension funds hold substantial assets in many economies and these assets have grown over time ~~especially in post World War countries~~. Pension funds can either be defined benefit or defined contribution types, depending on how the retirement benefits are determined. Both types of schemes primarily face investment/market risk. Good financial performance is important for all pension funds so that they can meet their current and future obligations. However, the parties that bear the overall risk are different between defined benefit risk and defined contribution pension schemes. Further in many countries, the number of defined contribution plans are either larger than, or have begun to overtake, defined benefit pension schemes. Therefore, providing this fundamental supplementary breakdown between the two types of autonomous pension plans is increasingly important.

- **Defined benefit pension funds** provide guaranteed levels of pension payouts to scheme members, who are almost exclusively employees. With a defined benefit pension scheme, the retirement payments are determined by an actuarial formula related primarily to the participants’ length of service and salaries, as well as by expected retirement ages, mortality rates, etc. This means that individual workers know what they will receive in retirement in relation to years worked. On the other hand, the sponsor/employer of a given defined benefit pension scheme undertake the risk of financial performance. The sponsor/employer might end up with an actuarial deficit on their pension fund if the regular assessment of the viability of the fund to make current and/or future benefit payments indicates insufficient reserves, and this gives rise to an underfunded pension liability which must be extinguished within a stated time frame. This type of actuarial liability is the responsibility of the sponsor/employer and can create a financial burden on the sponsor/employers. Under such a situation, employee contribution rates may also increase at some point, but the primary financial responsibility for an actuarial deficit remains with the sponsor/employer. **Defined contribution pension funds** are based on the scheme members’ and their employer’s contributions to the pension fund as well as the investment performance of the fund. Under a defined contribution pension scheme, individual contributions are often voluntary and typically matched ~~may include a contribution~~ by the employer. Defined contribution plans also include funds for self-employed persons. Under such a scheme, the retirement benefits are not determined and the financial

performance risk and general sufficiency of retirement saving risk is borne by the individual and can present a long-term financial stability risk for some households. , This situation can, under certain circumstances, create a potential future retirees' social support risk for the government.

### 3. Further Instrument Breakdowns in the SNA

29.92 The additional recommended details to better monitor and understand non-bank financial intermediation are confined to loans and financial derivatives (discussed in Chapter 25). The supplementary details are as follows:

- ***Loans, of which: repurchase agreements, securities lending with cash collateral, and margin lending.*** This was frequently applied in the build-up to the global financial crisis that began in 2007-08, where these funds were often used to increase the leverage of specific entities (using the liquid funds to buy assets that could then be used as collateral to raise more liquid funds, etc.). For that reason, it is important to have separate information on these types of loans, assessing their impact on liquidity measures and analyzing the degree to which financial corporations' subsectors are involved in liquidity transformation and in creation of additional leverage.
- ***Loans, of which: non-performing loans.*** As loans are recorded at nominal value, combining this with information on the amount of loans that are likely not going to be repaid, provides insight into the credit risk run by these entities, as well as a better perspective on the financial position and financial health of specific sectors in the economy.
- ***The market value of loan assets*** is also viewed as useful, but in the form of a memorandum item only for those jurisdictions that can compile such estimates.
- ***Financial derivatives*** information is important to monitor financial stability. For example, credit default swaps played a role during the global financial crisis that began in 2007-08, that created global repercussions. It is important to have data by risk category and sub-instrument, as well as by trading venue.

## **E. Link to monetary and financial statistics**

### **1. Introduction**

- 29.93 Chapters 12 and 14 describe the concepts and details of the financial accounts and the balance sheets, respectively. These chapters present the financial transactions and positions of each of the individual institutional sectors of the national economy as well as transactions and positions between residents and non-residents. These accounts are also closely related to the two components of the other changes in assets account (other changes in volume and revaluations) discussed in Chapter 13.
- 29.94 The information in the financial accounts and balance sheets is of analytical and policy interest in its own right and represents an important part of monetary and financial statistics. While the national accounts provide financial accounts and balance sheets for all sectors, among which the financial corporations sector ~~and subsectors and subsectors~~, the monetary and financial statistics (MFS) are primarily concerned with stocks and flows of assets and liabilities of financial corporations only. Both sets of accounts for financial corporations are closely tied to each other. In some economies, the SNA financial corporations' statistics are the source data for the MFS, whereas in others the MFS constitute source data for the SNA financial accounts and balance sheets.
- 29.95 This section discusses the main similarities and differences between the SNA and the MFS. Further detail on monetary and financial statistics can be found in the Monetary and Financial Statistics Manual and Compilation Guide (MFSMCG), International Monetary Fund. Other useful references include the *Manual on Sources and Methods for the Compilation of ESA Financial Accounts (Eurostat)*, the *Monetary Financial Institutions and Market Statistic Manual* (European Central Bank) and in *Financial Production, Flows and Stocks in the SNA* (United Nations and the European Central Bank).

### **2. Coverage of institutional sectors and sequence of accounts**

#### **Sectors and subsectors**

- 29.96 The SNA covers all institutional sectors and subsectors of the economy, with the purpose of constructing an integrated sectoral matrix of transactions, other flows, and balance sheets, as well as a times series by institutional sector and subsector. This structure displays the interactions across sectors and subsectors that shed light on how the economy functions over time. The principal sectors include non-financial corporations; financial corporations; government; non-profit institutions serving households (NPISH); households; the national economy (as the aggregate of the preceding sectors); and the accounts for all flows and stocks between residents and non-residents, from the rest of the world perspective (otherwise understood as the balance of payments, where the perspective of the domestic economy is taken as a starting point). Corporations and governments have subsectors associated with them in significant detail. For non-financial corporations, the subsectors are: public, national private and foreign controlled corporations. Government is split into central, state, and local levels, as well as social security funds (which can be allocated to their level of government). In the case of the financial sector, it is disaggregated into nine unique subsectors, as already explained in section B: central bank, other depository corporations except the central bank, money market funds, non-money market investment funds, other financial intermediaries except insurance corporations and pension funds, financial auxiliaries, captive financial institutions and moneylenders, insurance corporations, and pension funds.
- 29.97 The MFS puts the emphasis on the financial stocks and flows between key sectors of the economy and between resident institutional sectors and non-residents, with a special focus on financial corporations. As such, it defines and acknowledges the other institutional sectors as counterparts. Some reconcilable differences with SNA exist. The counterpart sectors households and NPISH are aggregated. General government subsectors' counterparts are split into central government and state government and local governments, with social security funds presented at the level of government at which they operate. The counterpart non-financial corporations are split between public and other.
- 29.98 More significant, but also reconcilable differences, exist for financial corporations. Deposit-taking corporations play an important role in the MFS statistics. The MFS financial corporations sector is divided into three main subsectors: central bank, other depository corporations (ODCs) that combine deposit-taking

corporations except the central bank and money market funds (MMFs), and other financial corporations (OFCs) that combine the SNA financial subsectors, from non-MMF investment funds to pension funds (although the Euro area MFS contains some additional subsector details). For monetary policy purposes, the focus is on the consolidated data for depository corporations. For broader macro-economic analysis, there is increasing focus on the consolidated OFCs data. A final difference in subsector coverage is that offshore banks that do not issue liabilities in broad money (i.e., they only take deposits from non-residents) are classified with other financial corporations in MFS, whereas SNA classifies these as deposit-taking corporations.

### **Sequence of economic accounts**

- 29.99 The SNA displays a complete set of transactions in the non-financial accounts (production account, generation of earned income account, allocation of earned income account, transfer income account, and capital account) as well as flows (financial transactions and other flows) for each category of financial assets and liabilities and for each of the institutional sectors and subsectors of the national economy and of the rest of the world. The sequence of accounts is completed by the opening and closing balance sheets (i.e., stocks of assets, non-financial as well as financial, and liabilities), which describes the result of a period's transactions and other flows on the assets, liabilities and net worth positions of each sector and subsector.
- 29.100 The MFS is focused on financial activity and positions of financial corporations, and only presents a partial sequence of accounts restricted to financial accounts, balance sheets, revaluations and volume changes. For each financial instrument, a set of entries equivalent to an asset account is shown, that is: opening stock, transactions, valuation changes, other changes in volume, and closing stock. Where the SNA and MFS overlap, the sequence of accounts is identical. However, the quadruple entry accounting of the SNA (the simultaneous application of vertical and horizontal entries) is not fully possible in monetary statistics, except in the case of pure financial transactions/positions that take place within the sectors covered by the monetary statistics.

### **Conceptual and accounting differences**

- 29.101 For the most part, the SNA and MFS follow the same principles. It can be stated that the basic accounting rules, concept of residence, time of recording (accrual accounting), and the classification of financial assets and liabilities are consistent between the SNA and MFSMCG. Nevertheless, there are some differences, with the main ones briefly discussed below.

### **Consolidation**

- 29.102 SNA follows the principle of non-consolidated accounts, such that balance sheet positions as well as transactions and other flows are presented gross so as to match corresponding entries across the institutional sectors and categories. MFS adheres to this general principle but allows for some degree of consolidation in the financial corporations sectors for monetary statistics' purposes. This entails the cancelling out of stocks and flows that arise from financial claims and corresponding obligations among institutional units within the same subsector. The practice involves the three subsectors of the financial corporations' sector: central bank, other depository corporations, and other financial corporations. Unconsolidated data, however, are available.

### **Classification and breakdowns of financial instruments**

- 29.103 Assets and liabilities are defined similarly for the most part; however, the level of detail can be different between the SNA and MFS with MFS providing some additional details, reflecting the different uses of the two datasets. Some important differences are noted below.

### *Money measures*

- 29.104 Money is very important as a financial variable. But the wide range of ways in which money is defined in different countries precludes a simple definition in the SNA. The composition of broad money and other monetary aggregates varies widely across countries and encompasses many classes of deposits. In addition, many countries compile a range of money measures, as well as broad liquidity measures. Even within a single country, innovation, deregulation, or technical progress may cause definitions of broad money to shift over time in response to changes in financial instruments and the organization of money markets.
- 29.105 The MFSMCG offers a more elaborate discussion on money aggregates, focusing on the characteristics of the financial instruments that should be included as part of broad money. The countries have, nonetheless, the discretion to tailor the generic definition to the characteristics of their economy while still ensuring overall consistency in the measure of broad money. Although the specific components of broad money may vary across countries, in all cases the coverage of financial instruments included in broad money is used to identify those financial corporations that issue liabilities included in broad money. Such financial institutions are described as depository corporations.
- 29.106 The MFS presents currency deposits in more detail than [the](#) SNA for monetary policy purposes. In addition, the MFS requires a breakdown of all assets and liabilities (excluding equity) into domestic and foreign currency. The SNA does not explicitly require this breakdown, although for certain calculations (e.g., holding gains and losses in foreign currency denominated items in the revaluation account) this split is implied for compilers.

### *Interbank positions*

- 29.107 In the SNA interbank positions are generally not shown as a separate category under the various financial instruments. The treatment is slightly different in the MFSMCG. Interbank (inter-depository corporations) positions are identified fully by all relevant instrument categories (except for equity). And when there is uncertainty between a loan and a deposit, it is recorded under other deposits.

### *Equity liability and net worth*

- 29.108 In the SNA, the equity liability of financial corporations is reported at market value or an approximation of this market value for unlisted equity. For the MFS, equity is valued at book value and is split into five components: funds contributed by owners, retained earnings, current year results, general and special reserves, and valuation adjustments.
- 29.109 In the SNA, net worth is defined as the value of all of the assets owned by an institutional unit in a (sub)sector less the value of its outstanding liabilities (including equity). The MFS does not have a concept of net worth, although a partial net worth (referred to as financial net worth) can be calculated as the difference between financial assets and liabilities (including equity).

### *Provisions for loan losses*

- 29.110 The treatment of provisions for loan losses is notably different between the SNA and MFS, and both treatments have their distinct purposes. For simplification, the discussion below assumes that all loans are denominated in domestic currency.
- 29.111 Lending institutions calculate allowances against their loan portfolios, although there may be some instances where this practice is not followed. The *allowance account* is deducted from their loan assets in each period. The changes in the allowance account are typically led by *new provisions* against non-performing loans – that is, loans that are a specified number of days in arrears on principal/interest payments (criteria which can differ across economies). In other words, potential losses are accounted for on an accrual basis, consistent with financial accounting. Loan assets are thus “written down” reflecting *potential losses* as opposed to *actual losses*, or *write-offs* of the assets. The allowance represents an amount considered appropriate to cover estimated losses, with a matching appropriation from retained earnings to reserves on the other side of the

ledger.

- 29.112 The allowance account may contain different types of entries, depending on what has transpired in any given period, which generates a closing balance different from the opening balance. These entries include new provisions (added) on any new nonperforming loans, loan recoveries (deducted) if the loans begin generating payments again, loan write-offs (deducted) removed from the account. Write-offs are permanently removed from loans as a separate adjustment outside of the allowance account, though they are almost always initially accounted for in allowances (as part of non-performing loans) and must be reversed when the losses are realized. In this sense, the terminology is important: The balance item deducted from ongoing loan assets for non-performing loans is called *loan allowances* or *accumulated net provisions on loans*. Likewise, the change in this balance is referred to as the *changes in the loan allowance account* or the *net new provision on loans*. Both net new provisions and write-offs are expensed on the financial corporation's income statement, with write-offs automatically excluded from net provisions (as described above) to avoid double-counting.
- 29.113 The SNA does not follow the above accounting for these adjustments to loans. Income statement items related to net new provisions and write-offs are not picked up by national accountants for the non-financial accounts, as the provisions are not relevant in this context and write-offs are treated as volume changes. On the SNA balance sheet, accumulated net provisions (or allowances) on loans are ignored. This means that they are added back to the loan balances, and the loan assets are recorded at gross values less any write-offs. In the financial account, transactions are measured as the first difference of these loan balances. Alternatively, if the "net of allowances" source data are used to calculate the transactions, an adjustment is required to account for any changes in the allowance account between periods. More specifically, net new provisions (including write-offs) are added to the first difference of the loan balance to estimate transactions in loans. In the less common instances where loan allowances are not accounted for in the source data, transactions would be measured as the first difference of the loan balances plus write-offs in the period.
- 29.114 In some jurisdictions, SNA source data may only provide the loans net of allowances with no explicit allowance account. Sometimes the allowance account may only be available annually (and with a lag) from the complete balance sheet statements, but the net provisions on the income statement are usually available quarterly. In these cases, quarterly estimates of the allowance account will have to be made of gross loans by summing the net new provisions for each period. Transactions would then be calculated as described above.
- 29.115 The SNA treatment can be summarized as follows: loans are shown gross of accumulated provisions or allowances, but write-offs are deducted from loans and shown on the other changes in the volume of assets account; and transactions are adjusted [first for](#) differences. This treatment has the advantage of reconciling debtor and creditor balances/transactions across the sectors of the economy. Having said that, loan allowances or accumulated net provisions are recommended as a memorandum item in the SNA.
- 29.116 The MFS has the same treatment as the SNA for write-offs. However, provisions are treated somewhat differently in the MFS. Loan assets are also valued at nominal value and are shown gross, but net accumulated provisions are accounted for as a liability on the balance sheet and recorded under other accounts payable (with a volume change offset in equity). This MFS treatment has the advantage of recognizing the provisions, but this approach is not feasible in the SNA given its requirement to balance all assets and liabilities (in this case, loans and other receivable/payables by creditor and debtor) by instrument across the institutional sectors. However, the SNA does recommend compiling supplementary items on provisions; see chapter 14.

## Chapter 30: ~~Chapter 30.~~ General government and the public sector (revised title)

### (OLD Chapter 22: The general government and public sectors)

public sectors)

#### 4.A. Introduction

- 30.1 A major strength of the SNA is the ability to compile accounts for whole sectors, individual units, or some intermediate levels and to aggregate the accounts in different ways. Disaggregating the economy into various sectors and subsectors makes it possible to observe and analyse the interactions between the different parts of the economy for purposes of policymaking. Particular interest is given to the general government sector, as defined in chapter [45](#) and the public sector, as defined in this chapter. Many of the concepts in this chapter have been described in a number of previous chapters. This chapter aims to bring these together, give some more elaboration on how they might be put into practice and gives a link to other systems of economic statistics particularly aimed at government such as the [GFSM2001](#), the [ESA95 Manual on Government Debt and Deficit \(Eurostat, 2002a\)](#) and the [External Debt Guide](#) *Government Finance Statistics Manual*, *Eurostat's Manual on Government Deficit and Debt*,<sup>-</sup> and the [External Debt Statistics Guide for Compilers and Users](#).
- 30.2 The powers, motivation and functions of government are different from those of other sectors. Governments use their powers to pass laws affecting the behaviour of other economic units. They are able to redistribute income and wealth largely by means of taxes and social benefits. The accounts for the general government sector show how goods and services provided to the community as a whole or to individual households are financed mainly by revenue raised. The range of goods and services the government provides, and the prices charged are based on political and social considerations rather than on profit-maximization.
- 30.3 Fiscal operations are carried out by the government and financed through the budget under the usual budgetary procedures. However, some operations ~~originated~~directed by government units may ~~require the intervention of~~ be carried out by entities ~~which are not ruled by~~outside the legal government framework, including public corporations. ~~These actions may be described as quasi~~Quasi-fiscal activities; operations are government operations carried out by institutional units other than general government units.
- 30.4 Operations related to privatization and restructuring public corporations, securitization of assets using the intervention of special purpose ~~entities~~units, including those abroad, may be described in this way. Though such operations are not reported in the budget and might escape the usual control procedures, they may have a significant impact on government revenue ~~and~~, expenditure and debt.
- 30.5 As well as providing services directly, governments often fulfil their public policy objectives through public corporations (for example, railways, airlines, public utilities and public financial corporations). A public corporation may be required to provide services to areas of the economy that would not be covered otherwise by means of subsidized prices. As a result, the public corporation may operate with a reduced profit or at a loss.
- 30.6 ~~In order to~~To analyse the full impact of government on the economy,<sup>-</sup> it is, therefore, ~~it is~~ useful to form a sector consisting of all the units of general government and all public corporations. This composite sector is referred to as the public sector.
- 30.7 For the general government sector and the public ~~sectors~~sector, in addition to the usual sequence of economic accounts of the SNA, the accounts can be presented in a manner that is more suitable for government finance analysts and policymakers. The latter increasingly use aggregates and balancing items defined in terms of the

concepts, definitions, classifications and accounting rules of the SNA so that these aggregates can be related to other macroeconomic variables and compared with the same items in other countries. Some of these items, such as saving and net lending or borrowing, are already available in the sequence of [economic](#) accounts. Other items, such as total revenue, total expense and total outlays, the tax burden, the net operating balance and total debt, do not appear as such in the SNA. Aggregates and balancing items of this nature can be used to assess the use of resources to produce individual and collective services, the need to collect taxes and other revenues, the ability of government to borrow and repay debt and the sustainability of the desired level of government operations.

30.8 The present chapter gives an overview of this so-called public finance or government finance presentation of the accounts. In ~~order to derive~~ this presentation, the transactions in the SNA current and capital accounts are rearranged to derive aggregates and balancing items of specific interest to the general government and public sectors. For example, a combination of taxes, ~~user fees and social contributions,~~ grants from other governments [and other revenue items](#) can be aggregated to form total revenue, as the amount available from operations to fund government services.

~~30.9 Section B summarizes the identification of government units and other units controlled by government units and explains how those units are grouped into sectors in the SNA.~~

~~30.10 Section C describes the presentation of government finance statistics.~~

~~30.11 Section D addresses a number of accounting issues that are unique to, or exceptionally important for, government.~~

~~30.12~~30.9 Finally, section B summarizes the identification of government units and other units controlled by government units and explains how those units are grouped into sectors in the SNA. Section C describes the presentation of government finance statistics. Section D addresses accounting issues that are unique to, or exceptionally important for, government. Section E shows how information about the public sector may be prepared in a manner roughly parallel to the government finance statistics presentation described in section D. Finally, section F discusses the links to International Public Sector Accounting Standards (IPSAS).

## **1. Data sources**

~~30.13~~30.10 In practice, macroeconomic accounts can seldom be built up by simply aggregating the relevant microdata. Government is an exception in that the statistics for government units and public corporations are often derived directly from the microdata in government financial accounting databases. As a result, compilers of statistics for the government units and public corporations usually draw more heavily on accounting information than [on](#) the results of statistical enquiries. In particular, the development ~~in recent years~~ of International Public Sector Accounting Standards by the International Public Sector Accounting Standards Board of the International Federation of Accountants has increased the need for clear guidance on the compilation of government finance statistics so that the detailed accounting data can be transposed correctly into the framework of the SNA. Such guidance is especially important when the [government financial](#)~~government's~~ accounts are compiled on a cash basis and must be converted to an accrual basis to comply with the accounting basis of the SNA.

## **2. Consolidation**

~~30.14~~30.11 As a rule, the entries in the SNA are not consolidated. Consolidation involves the elimination of those transactions or debtor/creditor relationships that occur between two transactors belonging to the same institutional sector or subsector. As stated in chapter 34, however, consolidation may be relevant for the general government sector. For example, information on debt owed by government units to units outside the general government sector may be more relevant than gross figures that include debt owed to other government units. ~~Guidance on consolidation is provided~~Consolidation in GFSM and the SNA is discussed in Section C.

## **2.B. Defining the general government and public sectors**

~~30.15~~30.12 General government units include ~~some NPIs and public enterprises not treated as corporations, non-market producers controlled by government, while the public sector comprises all institutional units controlled, directly or indirectly, by government.~~ The public sector ~~includes~~can be separated into general government units and public corporations. Public corporations are market producers, which are institutional units that provide all or most of their output to others at prices that are economically significant. To identify which ~~NPIs~~units are included in general government, the conditions for control by government and for prices to be considered economically significant must be identified. To determine ~~which enterprises are treated as~~whether a unit controlled by government is a public ~~corporations and which as~~corporation or part of general government, it is necessary to ~~specify conditions for control by government and the concept of~~determine whether or not it charges economically significant prices.

~~30.16~~30.13 ~~In order to~~To identify the units falling in ~~both~~ the general government sector ~~and the public sector,~~ it is helpful to begin by restating the definition of government units given in ~~paragraphs 4.117 to 4.118;~~5.178-5.179. The ~~discussion on~~discussions of what is meant by control by government and by economically significant prices ~~follows~~follow.

### **1. Government units**

~~30.17~~30.14 *Government units are unique kinds of legal entities established by political processes that have legislative, judicial or executive authority over other institutional units within a given area.* Viewed as institutional units, the principal functions of government are to assume responsibility for the provision of goods and services to the community or to individual households and to finance their provision out of taxation or other ~~incomes~~resources, to redistribute income and wealth by means of transfers, and to engage in non-market production. In general terms:

- a. A government unit usually has the authority to raise funds by collecting taxes or compulsory transfers from other institutional units. A government unit must have funds of its own either raised by taxing other units or received as transfers from other government units, and it must have the authority to disburse some, or all, of such funds in the pursuit of its policy objectives. It must also be able to borrow funds on its own account.
- b. Government units typically make three different kinds of final outlays:

The first group consists of actual or imputed expenditures on the free provision to the community of collective services such as ~~public administration, security and~~ defence, the maintenance of law

~~enforcement and order, provision of public health~~ infrastructure for transport, the protection of environment, etc. that are organized collectively by government and financed out of general taxation ~~or~~ and other government income or borrowing.

The second group consists of expenditures on the provision of goods or services free, or at prices that are not economically significant, to individual households, such as publicly provided health care and education. These expenditures are deliberately incurred and financed out of taxation ~~or~~ and other government income or borrowing by government in the pursuit of its social or political objectives, even though individuals could be charged according to their usage.

\* The third group consists of transfers paid to other institutional units, mostly households, ~~in order to~~ redistribute income or wealth, such as social security and social assistance benefits.

~~30.18~~30.15 Within a single ~~economy~~ territory there may be many separate government units when there are different levels of government ~~at, specifically central, state or, and local levels, there may be many separate government units. Social~~ governments. In addition, social security funds ~~also~~ constitute government units.

~~30.19~~30.16 In all countries, there is an institutional unit of the general government sector ~~important~~ distinguished by its importance in terms of size and power, ~~in particular~~ particularly the power to exercise control over many other units. This unit is often referred to as the national government and is the unit covered by the main budget account. It is a single unit of the central government that encompasses the fundamental activities of the national executive, legislative and judiciary powers. Its revenues, as well as its expenses and expenditures are normally regulated and controlled by a Ministry of Finance or its functional equivalent and by means of a general budget approved by the legislature. Most of the ministries, departments, agencies, boards, commissions, judicial authorities, legislative bodies and other entities that make up this central government unit are ~~not separate institutional units but are~~ part of ~~this~~ the primary central government unit, ~~not separate institutional units~~. This is because they generally do not have the authority to own assets, incur liabilities, or engage in transactions in their own right. If there are state or local governments ~~then~~, it is likely that each of these governments will also have a primary government unit that includes the principal executive, ~~and~~, possibly, legislative and judicial powers.

~~30.20~~30.17 In addition, there may be government entities with a separate legal identity and substantial autonomy, including discretion over the volume and composition of their expenses and outlays and a direct source of revenue, such as earmarked taxes. (The terms expense, outlay and revenue are commonly used in the presentation of government accounts. Their definitions and relationship to SNA concepts are covered in section C.) Such entities are often established to carry out specific functions, such as road construction or the non-market production of health or education services. These entities should be treated as separate government units if they maintain full sets of accounts, own goods or assets in their own right, engage in non-market activities for which they are held accountable at law, and are able to incur liabilities and enter into contracts in their own right. Such units are often referred to as extrabudgetary units because they have separate budgets and any transfers from the main budget account are supplemented by their own sources of revenue. ~~Budgets~~ Budget practices vary widely among countries and various terms are often used to describe these units. These units are classified in the general government sector to the extent that they are non-market producers and are controlled by another government unit.

~~30.21~~30.18 A social security fund is a particular kind of government unit that is devoted to the operation of one or more social security schemes. A social security fund must satisfy the general requirements of an institutional unit. ~~That – that~~ is, it must be separately organized from the other activities of government units, hold its assets and liabilities separately and engage in financial transactions on its own account.

30.2230.19 As noted earlier, ~~NPIs that are~~ non-market producers ~~and that~~ are controlled directly or indirectly by ~~one or more~~ government units are also units of the general government sector. ~~Although~~ Even if they ~~may are~~ legally ~~be~~ established to be independent from government, they are considered to be carrying out government policies and are effectively part of government. Governments may choose to use non-profit institutions or other legal entities rather than government agencies to carry out certain government policies ~~because NPIs may be seen as not subject to political pressures.~~ For example, research and development, and the setting and maintenance of standards in fields such as health, safety, the environment and education are areas in which NPIs such units may be more effective than government agencies.

30.2330.20 ~~The case of units~~ Entities engaged in financial activities ~~needs~~ need special consideration. As described in paragraph 4.67, a unit 5.100, an entity set up by government with functions similar to a captive financial institution is treated as an integral part of general government and not as a separate unit if it has no powers to act independently, is restricted in the ~~number~~ types of transactions that it can engage in, does not carry the risks and rewards associated with the assets and liabilities it holds, and is resident in the same economy. If the ~~unit~~ entity is non-resident, it is treated as a separate unit but the transactions it undertakes as quasi-fiscal operations and the related positions it holds are ~~reflected~~ mirrored in imputed transactions ~~between that unit and positions of the controlling government.~~ In particular, if the non-resident unit borrows abroad, it is regarded as lending the same amount to government and on the same terms.

30.2430.21 At the same time, the general budget of any government level might control market producers satisfying the criteria to be a quasi-corporation as defined below. These units should not be classified in the general government sector, but in the non-financial or financial corporations sector, as appropriate. As public units, they are, however, part of the public sector.

## **2. NPIs controlled by government**

30.2530.22 Control by government is one of the requirements for an NPI to be treated as a government unit. The other, operating as a non-market producer, is discussed below. The criteria for deciding whether an NPI is controlled by government or not ~~is~~ are described in paragraph 4.92, 5.136. They are summarized here for convenience.

30.2630.23 Control of an NPI is defined as the ability to determine the general policy or programme of the NPI. All NPIs allocated to the general government sector should retain their identity as NPIs in statistical records, to facilitate analysis of the complete set of NPIs. To determine if an NPI is controlled by the government, the following five indicators of control should be considered:

- a. The appointment of officers;
- b. Other provisions of the enabling instrument;
- c. Contractual agreements;
- d. Degree of financing by government; and

- e. Risk exposure.

A single indicator could be sufficient to establish control in some cases but sometimes a number of separate indicators may collectively indicate control. A decision based on the totality of all indicators will necessarily be judgmental in nature, but the judgements should be consistent for similar cases.

### **3. Corporations controlled by government**

30.2730.24 To be classified as a public corporation, a corporation must ~~both not only~~ be ~~both~~ controlled by another public unit, ~~but it also must~~ satisfy the criteria to be a market producer. Control is defined as the ability to determine the general policy or program of an institutional unit. Government is in a position to exercise control over many kinds of units: miscellaneous extrabudgetary agencies, non-profit institutions and corporations (non-financial or financial). The criteria for control of a corporation are described in paragraphs 4.77 to 4.80, 4.77-5.121 to 4.805.125. The key factors to be considered are

- a. Ownership of the majority of the voting interest;
- b. Control of the board or other governing body;
- c. Control of the appointment and removal of key personnel;
- d. Control of key committees of the entity;
- e. Golden shares and options;
- f. Regulation and control;
- g. Control by a dominant customer or group of customers; and
- h. Control attached to borrowing from the government.

Although a single indicator could be sufficient to establish control in some cases, in ~~others~~ other cases a number of separate indicators may collectively indicate control. A decision based on the totality of all indicators must necessarily be judgmental in nature, but the judgements should be consistent for similar cases.

### **4. Economically significant prices**

30.25 In addition to the test of control by a government, a test of whether the unit operates as a non-market producer is necessary to determine whether it is a general government unit or a public corporation. Units controlled by another public sector unit that operate as market producers are classified as public corporations.

~~30.28~~30.26 To be considered ~~as~~ a market producer, a unit must provide all or most of its output to others at prices that are economically significant. *Economically significant prices are prices that have a significant effect on the amounts that producers are willing to supply and on the amounts purchasers wish to buy. These prices normally result when:*

- a. *The producer has an incentive to adjust supply either with the goal of making a profit in the long run or, at a minimum, covering capital and other costs; and*
- b. *Consumers have the freedom to purchase or not purchase and make the choice on the basis of the prices charged.*

~~30.29~~30.27 These conditions usually mean that prices are economically significant if sales cover the majority of the producer's costs and consumers are free to choose whether to buy and how much to buy on the basis of the prices charged. Although there is no prescriptive numerical relationship between the value of output (excluding both taxes and subsidies on products) and the production costs, one would normally expect the value of goods and services sold (the sales) to average at least half of the production costs over a sustained multiyear period. However, for financial public corporations, this test is generally not applicable because property income and holding gains tend to be very important for financial institutions.

~~30.30~~30.28 Because economic circumstances vary considerably, it may be desirable to accept different thresholds to achieve consistent economic measurement over time, between units and across countries. In principle, the distinction between market and non-market should be made on a case-by-case basis.

~~30.31~~30.29 It can be presumed that prices are economically significant when the producers are private corporations. When there is public control, however, the unit's prices may be modified for public policy purposes. This may cause difficulties in determining whether the prices are economically significant. Public corporations are often established to provide goods that the market would not produce in the desired quantities or at the desired prices. Even when the sales of such corporations ~~may~~ cover a large portion of their costs, one can expect that they respond to market forces quite differently than would private corporations.

~~30.32~~30.30 It is likely that corporations receiving substantial government financial support, or that enjoy other risk reducing factors such as government guarantees, will act differently from corporations without such advantages because their budget constraints are softer. A non-market producer is a producer that faces a very soft budget constraint so that the producer is not likely to respond to changes in the economic conditions in the same way as market producers.

## Suppliers of goods and services to government

~~30.33~~30.31 The question arises whether ~~units~~government-controlled entities supplying goods and services to government should be treated as market or non-market producers. The ~~essential question~~supplier of the goods and services to government is ~~whether~~not a market producer if it is a dedicated provider of ancillary services. Dedicated providers of ancillary services generally do not satisfy the criteria to be institutional units. It can also be presumed that the producer is not a market producer if the unit provides the goods and services in the absence of competition with private producers and the choice of supplier is not based on price. This is true regardless of whether the supplier is the only supplier and whether the government is the only customer of the supplier.

## Definition of sales and costs

~~30.34~~30.32 ~~In order to~~To assess whether a producer is a market producer, it is necessary to carry out a comparison between the receipts from sales and the production costs of the products. Sales are measured before any taxes applicable to the products are added. Sales exclude all payments received from government unless they would be granted to any producer undertaking the same activity. Own account production is not considered as part of sales in this context.

~~30.35~~30.33 Production costs are the sum of intermediate consumption, ~~compensation~~remuneration of employees, ~~consumption of fixed capital and other~~ taxes on production. ~~Further, rent payable for the use of non-produced assets, depreciation (and depletion if the unit is to be treated as a market producer, relevant), and a return to capital is included~~used in production costs. Subsidies on production are not deducted.

## 5. A decision tree for public units

~~30.36~~30.34 Figure 2230.1 shows the relationship between the general government sector, the public sector and the other main sectors of the domestic economy.

~~30.37~~30.35 As explained in paragraph 4.117, 5.1785.183 government units are established by political processes and have legislative, judicial or executive authority over other institutional units within a given territory. These units belong to the general government sector and so to the public sector also. In order to determine which other institutional units belong to the general government sector and which to the public sector, the decision tree described in figure 45.1 should be followed, using the following sequential questions:

- a. Is the entity of interest an institutional unit? If it is not, but is resident, then it is treated as part of the unit that controls it. If it is not an institutional unit but is non-resident, it is treated as a quasi-corporation in the economy in which it is resident.

~~b.~~ Is the unit controlled by government or another public corporation?

~~b.c.~~ Is the unit a market or non-market producer according to the criteria given immediately above?

~~c.~~ Is the unit controlled by government or another public corporation?

~~30.38~~30.36 The answers to the last two questions lead to allocations to sectors as follows:

- a. If the unit is a market producer and not controlled by government, it is a part of neither the general government sector nor the public sector.

- b. If the unit is a market producer and controlled by government or another public corporation, it is not part of general government but is part of the public sector.

- c. If the unit is a non-market producer and controlled by government, it is part of the general government

sector and the public sector.

- d. If the unit is a non-market producer but not controlled by government, it is treated as an NPISH. It is a part of neither the general government sector nor the public sector.

**Figure 30.1: The public sector and its relation to institutional sectors**  
**[Figure 22.1 of SNA2008 to be inserted here]**

## **6. Subsectors of the general government sector**

~~30.39~~30.37 As described in chapter 45, the general government sector may be ~~subsectored~~sub sectored in either of two ways. One method is to have up to three subsectors; one for central government, one for state government and one for local government, with social security included at any level where relevant. In some cases, there may be only one or two levels of general government, and in some cases more levels of government must be accommodated within the three-level structure. The other method of subsectoring is to exclude social security funds from each level of government and have a separate subsector for social security funds covering all levels of government. The choice of classification ~~used~~ will depend on whether social security funds are independent of the level of government where they operate or not.

~~30.40~~30.38 Greater detail on subsectoring general government is given in section F of chapter 45.

## **7. Subsectors of the public sector**

~~30.41~~30.39 It is possible to construct subsectors of the public sector to meet analytical demands. Two methods of subsectoring the public sector may be considered. In the first, the public sector could be divided into the general government sector as one subsector and the aggregate of all public corporations as a second subsector. The further detail could also be provided by dividing general government into detailed subsectors of central government, state government, local government and social security funds, and public corporations might be further divided into non-financial public corporations, financial public corporations other than the central bank, and the central bank.

~~30.42~~30.40 Secondly, the public sector could be divided by the geographical level of ~~government~~the authority in the same way as the general government sector is. In this case, the subsectors would be the central government public sector, the state government public sector, and the local government public sector. Each of these subsectors would consist of the corresponding subsector of the general government sector plus all public corporations controlled by a unit of that level of government. If a unit is controlled in part by a unit at one level of government and in part by a unit ~~in at~~ another part level of government, an allocation must be made to one or the other level of government depending on factors such as the degree of control exercised by each of the controlling units. Social security funds could form a separate subsector or could be combined with each level of government. It should be noted that if there is a separate fund to meet government employee pensions, this fund should be excluded from social security funds.

## **8. Borderline cases**

30.4330.41 Specific guidance on when certain entities created by government units are to be included in the public sector or not is needed. The entities concerned include quasi–corporations, restructuring agencies, special purpose ~~entities~~units, joint ventures ~~and~~, supranational authorities, ~~and trusts~~.

**Figure 22.1: The public sector and its relation to institutional sectors**

## Quasi-corporations

30.4430.42 Quasi-corporations are unincorporated enterprises that function as if they were corporations. Quasi-corporations are treated in the SNA as if they were corporations: that is, as institutional units separate from the units to which they legally belong. Thus, quasi-corporations owned by government units are grouped with corporations in the non–financial or financial corporate sectors.

30.4530.43 The intent behind the concept of a quasi-corporation is to separate from their owners those unincorporated enterprises that are sufficiently self-contained and independent of their owners that they behave in the same way as corporations. If they function like corporations, they must keep complete sets of accounts. Indeed, the existence or possibility to construct a complete set of accounts, including balance sheets, for the enterprise is a necessary condition for it to be treated as a separate institutional unit, otherwise it would not be feasible from an accounting point of view to distinguish the quasi-corporation from its owner.

30.4630.44 In order to be treated as a quasi-corporation the government must allow the management of the enterprise considerable discretion not only with respect to the management of the production process but also the use of funds. Government quasi-corporations must be able to maintain their own working balances and business credit and be able to finance some or all of their capital formation out of their own saving, financial assets or borrowing. The ability to distinguish flows of income and capital between quasi–corporations and government implies that, in practice, their operating and financing activities must be separable from government revenue or finance statistics, despite the fact that they are not separate legal entities. The net operating surplus of a government–owned quasi-corporation is not a component of government revenue and the accounts for government record only the flows of income and capital between the quasi-corporation and government.

## The case of restructuring agencies

30.4730.45 Some public units are involved in the restructuring of corporations, either non-financial or financial. These corporations may or may not be controlled by government. Restructuring agencies may be long-standing public units or agencies created for this special purpose. Government may fund the restructuring in various ways, either directly, through capital injections (capital transfer, loan or acquisition of equity) or indirectly, through granting guarantees. Units such as restructuring agencies have little output so the usual criterion of whether the output is market or non-market in determining when the unit is part of general government is not sufficient. Instead, the following propositions should be considered:

- a. A unit that serves only government is more likely to be included in general government than one that deals with other units ~~as well~~.
- b. A unit that sells financial assets at other than market values is more likely to be in the general

government sector than not.

- c. A unit that takes on low risk because it acts with strong public financial support and legally or effectively on behalf of the government is ~~likely to be~~ included within general government.

~~30.48~~30.46 Restructuring agencies may operate in a number of ways. The following are two frequently-observed examples.

~~30.49~~30.47 A restructuring agency may undertake the reorganization of the public sector and the indirect management of privatization. Two cases may be considered:

- a. The restructuring unit is a genuine holding company controlling and managing a group of subsidiaries and only a minor part of its activity is dedicated to channelling funds from one subsidiary to another on behalf of the government and for public policy purposes. The unit is classified as a corporation and the transactions made on behalf of the government should be rerouted through the general government.
- b. The restructuring unit, whatever its legal status, acts as a direct agent of the government and is not a market producer. Its main function is to redistribute ~~national~~ income and wealth, channelling funds from one unit to the other. The restructuring unit should be classified in the general government sector.

~~30.50~~30.48 Another example of a restructuring agency is one mainly concerned with impaired assets, mainly in a context of a banking or other financial crisis. Such a restructuring agency must be analysed according to the degree of risk it assumes, considering the degree of financing of the government. Again, two cases may be considered:

- a. The restructuring agency borrows on the market at its own risk to acquire financial or non-financial assets that it actively manages. In this case the unit should be classified as ~~an institutional~~ unit in the financial corporations sector.
- b. The restructuring agency deliberately purchases assets at above market prices with direct or indirect financial support from the government. It is primarily engaged in the redistribution of ~~national~~ income (and wealth), does not act independently of government or place itself at risk and therefore should be classified in the general government sector.

### Special purpose ~~entities~~units

~~30.51~~30.49 Government units are always considered resident because, by definition, the economic territory of a country consists of the geographic territory administered by a government, as well as some territorial enclaves in the rest of the world, used by the government for diplomatic, military, scientific, or other purposes, normally with the formal agreement of the government of the country in which they are physically located. These enclaves are part of the general government sector.

~~30.52~~30.50 ~~Some governments~~Governments may set up special purpose ~~entities (SPEs)~~units, such as special purpose vehicles, or similar resident units, for financial convenience, the ~~SPE~~special purpose unit being involved in fiscal or quasi-fiscal activities (including securitization of assets, borrowing, etc.). Resident

~~SPE~~special purpose units that function in only a passive manner relative to general government and that carry out fiscal activities are not regarded as separate institutional units in the SNA and are treated as part of general government regardless of their legal status. If they act independently, acquire assets and incur liabilities on their own behalf, accepting the associated risk, they are treated as separate institutional units and are classified to sector and industry according to their principal activity.

~~30.53~~30.51 ~~Non-resident~~Non-resident special purpose units are referred to as special purpose entities (SPEs), as explained in [paragraph 5.86](#). SPEs are always classified as separate institutional units in the economy where they are established. When such entities ~~are~~have been created, care must be taken to reflect faithfully the fiscal activities of the government. All flows and ~~stock~~positions between the general government and the non-resident ~~SPE~~special purpose units (SPEs) should be recorded ~~when they occur~~ in the accounts for general government and the rest of the world.

~~30.54~~30.52 A government may create ~~a non-resident~~an SPE to undertake government borrowing or incur government outlays abroad. Even if there are no actual economic flows recorded between the government and the SPE related to these fiscal activities, transactions should be imputed in the accounts of both the government and the rest of the world to reflect the fiscal activities of the government undertaken ~~by the SPE, including borrowing. The special case of securitization units is discussed in section D through the SPE. Borrowing by the SPE is mirrored by an imputation of borrowing by the government from the SPE on the same terms and via the same type of financial instrument, and an associated increase in the government's equity in the SPE. Interest payments made by the SPE are treated as funded by interest received from the government. The expenditures of the SPE are re-routed through the government, and the imputed government expenditures have the same nature and counterparty (e.g., capital transfers to public corporations) as the actual expenditures of the SPE. Finally, any revenues of the SPE (e.g., fees from securitizations) are also rerouted through the government. (The special case of securitization units is discussed in section D.)~~

## Joint ventures

~~30.55~~30.53 Many public units enter into arrangements with private entities or other public units to undertake a variety of activities jointly. The activities could result in market or non-market output. Joint operations can be structured broadly as one of three types: jointly controlled units, referred to here as joint ventures; jointly controlled operations; and jointly controlled assets.

~~30.56~~30.54 A joint venture involves the establishment of a corporation, partnership or other institutional unit in which each party legally has joint control over the activities of the unit. The units operate in the same way as other units except that a legal arrangement between the parties establishes joint control over the unit. As an institutional unit, the joint venture may enter into contracts in its own name and raise finance for its own purposes. A joint venture maintains its own accounting records.

~~30.57~~30.55 The principal question to be considered here is [how to determine](#) whether the effective economic control of the joint venture establishes a public or a private unit. If a joint venture operates as a non-market producer, it must be the case that government is in effective control and ~~the joint venture~~ is classified as part of general government.

~~30.58~~30.56 If the joint venture is a market producer, it is treated as a public or private corporation according to whether it is or is not controlled by a government unit, using the same indicators as described above. Normally, the percentage of ownership will be sufficient to determine control. If, [however](#), the public and private units own an equal percentage of the joint venture, the other indicators of control must be considered.

~~30.59~~30.57 Public units can also enter into joint operating arrangements that do not involve establishing separate institutional units. In this case, there are no units requiring classification, but care must be taken to ensure that the proper ownership of assets is recorded and any sharing arrangements of revenues and expenses are made in accordance with the provisions of the governing contract. For example, two units may agree to be responsible for different stages of a joint production process or one unit may own an asset or a complex of related assets but both units agree to share revenues and expenses.

## Supranational authorities

~~30.60~~30.58 ~~Some countries~~Countries may be part of an institutional agreement that involves monetary transfers from the member countries to the associated supranational authority and vice versa. The supranational authority also engages in non-market production. In the national accounts of the member countries, the supranational authorities are non-resident institutional units that are part of the rest of the world and may be classified in a specific subsector of the rest of the world.

~~30.61~~30.59 Because the supranational authority is fulfilling the functions of a level of government, it is possible to construct a set of accounts for the authority as if it were a resident unit of the member country even though it remains non-resident. Such an additional account may provide a useful supplement for the analysis of the economic activities of the member countries.

## Trusts

30.60 Government and public sector units may create trusts. The trustees they name may, or may not, be part of the public sector. Furthermore, depending on the country's legal framework, the trust might be constituted as a private entity even when the risks and rewards remain with a government or public sector unit. Determining the sector classification of the trusts created by government or public sector units may require a case-by-case application of the tests for whether a trust or similar fund is an institutional unit shown in the decision tree of Figure 5.2 in Chapter 5 and a test of whether the unit is a market or non-market producer.

## 3.C. The government finance presentation of statistics

### 4.1. Introduction

~~30.62~~30.61 The sequence of economic accounts for all institutional units and sectors is described in chapters ~~67~~ to ~~43~~14. For the general government sector and, in some cases, the public sector, experience has shown that an alternative presentation, usually known as a government finance presentation or public finance presentation, of the stocks and flows is better suited to ~~certain analytical requirements~~fiscal analysis. This section gives a very brief overview of the way in which government accounts are presented in, ~~for example,~~ the ~~GFSM2001, which~~GFSM and of that presentation's conceptual differences from the SNA. The GFSM should be consulted for further explanation and discussion.

~~30.63~~30.62 Basically, the government finance presentation consists of transactions that increase net worth leading to an aggregate called revenue and transactions that decrease net worth, leading to the aggregate called expense. In addition, there are two main balancing items, net operating balance, and net lending or net borrowing. Additional accounts can be shown for other economic flows and balance sheets.

~~30.64~~30.63 The following section provides general information about the concepts involved in government

finance.

## 5.2. Revenue

~~30.65~~30.64 A revenue transaction is one that increases net worth. In the government finance presentation of the accounts, the concept of revenue is defined to include all ~~resources~~revenues acquired by government as recorded in the SNA current accounts and capital transfers receivable recorded in the capital account. Specifically, revenue can be determined as follows:

Revenue

*equals* Taxes,

*plus* Social contributions,

*plus* Other current revenue,

*plus* Capital transfers receivable.

~~30.66~~30.65 Government revenue is usually dominated by compulsory levies in the form of taxes and social contributions. For some levels of government, grants (transfers from other government units and international organizations) are a major source of revenue. Other general categories of revenue include finances, penalties, and forfeits, property income, sales of goods and services and miscellaneous transfers other than grants.

~~30.67~~30.66 ~~Estimating taxes and social contributions can be quite difficult. The problems involved and the recommended solutions are described in section D. Taxes are recorded in several of the accounts in the sequence of accounts.~~ An advantage of the government finance presentation is that all taxes can be presented as one category of revenue, with subclassifications according to the basis on which the tax was levied. In particular, both current and capital taxes can be shown under a single heading. In the SNA, taxes are recorded in several of the accounts in the sequence of economic accounts. The problems involved in estimating taxes and social contributions and their solutions are described in section D.

~~30.68~~30.67 Other current revenue covers property income, sales of goods and services, fines, penalties and forfeits, voluntary transfers other than grants and ~~miscellaneous premiums, fees, and unidentified revenue claims related to nonlife insurance and standardized guarantee schemes~~. The distribution of goods and services that are not sold at all, or sold for prices that are not economically significant, does not accord with the general notion of revenue as a transaction that increases net worth. As a result, only actual sales of goods and services, or goods and services produced by government but provided as ~~compensation~~remuneration in kind of employees ~~in kind~~ are included in revenue. (The goods and services provided as compensation in kind are treated as revenue because they offset expenditure.)

~~30.69~~30.68 Transfers from one government unit to another, often from the central or a state government to a lower level of government, can be quite important sources of government revenue. The government finance presentation allows all of these receipts to be collected into a separate category of revenue, usually labelled

grants. Other transfers, including subsidies, normally amount to much less and are reported separately. Property income may or may not be an important source of revenue, but in either case, it relates directly to the same category as in the allocation of primary earned income account except for the interest payable to financial intermediaries that is treated as implicit financial services on loans and deposits in the national accounts presentation but not in the GFS presentation.

### **6.3. Expense**

30.7030.69 An expense transaction is one that decreases net worth. In the government finance presentation of the accounts, the concept of expense is defined to include all uses expenditures incurred by government as recorded in the SNA current accounts and capital transfers payable as recorded in the capital account. Specifically, expense can be determined as follows:

Expense

*equals* Production expenses (compensation remuneration of employees, intermediate consumption and consumption of fixed capital depreciation),

*plus* Interest payable,

*plus* Subsidies,

*plus* Grants,

*plus* Social benefits,

*plus* Other current expenses,

*plus* Capital transfers payable.

30.7130.70 ~~The~~ Many of the differences between the government finance presentation ~~as in GFSM2001, for example, differs from the~~ and the SNA sequence of economic accounts ~~in involve expenses.~~ (See GFSM 2014, Appendix 7, for a ~~number of ways~~ general discussion of these differences.) The absence of a production account in the government finance presentation makes it impossible to show both the cost structure of own-account production and its final use. ~~Thus, for~~ For instance, the salaries of employees engaged in own-account capital formation are directly classified as acquisitions of gross capital formation and not as compensation remuneration of employees. Conversely, the salaries of employees ~~that who~~ produce social benefits in kind are recorded as compensation remuneration of employees and not again as (part of) expense on social benefits in kind. The government finance presentation also uses some labels and definitions that differ from those in the sequence of accounts and ~~also~~ introduces various simplifications. For example, outlays on ~~FISIM~~ implicit financial services on loans and deposits and insurance services are not distinguished from interest and net insurance premiums respectively.

30.7230.71 Governments typically produce many services and some goods and then distribute them free or at

prices that are not economically significant. In the SNA, the cost of these goods and services is recorded as a use when they are produced and again as a social benefit or final consumption expenditure when they are distributed. ~~To reduce unnecessary duplication, these~~ These costs are recorded only as production expenses in the government finance presentation ~~to avoid unnecessary duplication.~~

~~30.73~~30.72 In principle, retirement the GFS presentation, pension benefits paid to retired government employees and their survivors are considered ~~the liquidation~~ liquidations of ~~a liability~~ pension liabilities rather than a payment of a current expense. ~~However, They are therefore not included in practice~~ social benefits as reported in government accounts may include retirement benefits paid to government employees. If these transactions in pension liabilities are to be excluded, the ~~definition of social~~ contributions ~~must~~is also ~~be excluded from~~ more restrictive than in the SNA because contributions to employment-related pension schemes are recorded as incurrence of pension liabilities rather than as revenue ~~and~~. The net incurrence of pension liabilities of the item adjustment for changes ~~GFS presentation is known as the change~~ in pension entitlements ~~excluded from expense in the SNA.~~

## ~~7.~~ Outlays

## 4. Expenditure

~~30.74~~30.73 The purchase of a non-financial asset is not an expense because it has no net effect on net worth since it represents the exchange of one type of asset for another or the incurrence of a liability matched by the acquisition of an asset. It is, however, included in a total called expenditure outlays (or, sometimes, outlays expenditure). ~~Outlays are~~ Expenditure is defined as follows:

Outlays

Expenditure

*equals* Expense,

*plus* ~~Acquisitions less disposals of~~ Net investment in non-financial assets.

~~The net acquisition of~~ Net investment in non-financial assets is the sum of the gross capital formation and acquisitions less disposals of non-produced non-financial assets.

## 8.5. Net operating balance

~~30.75~~30.74 The net operating balance is defined as revenue less expense. It is the balance of all transactions that affect net worth. It is equivalent to the changes in net worth due to saving and capital transfers in the SNA sequence of economic accounts. It provides a measure of the sustainability of government policies as it represents the resources acquired or consumed by the government's current operations. Specifically:

Net operating balance

*equals* Revenue,

*less* Expense.

## **9.6. Net lending or net borrowing**

~~30.76~~<sup>30.75</sup> Net lending or net borrowing can be calculated as the net operating balance less the net ~~acquisition~~ investment in non-financial assets or total revenue less total outlays. It represents the amount the government has available to lend or must borrow to finance its non-financial operations. Specifically:

Net lending or net borrowing

*equals* Net operating balance,

*less* ~~Acquisitions less disposals of~~ Net investment in non-financial assets. or, alternatively:

Net lending or net borrowing

*equals* Revenue,

*less* ~~Outlays~~ Expenditure.

~~30.77~~<sup>30.76</sup> Net lending or net borrowing is also the balancing item of the financial account, although in practice a statistical discrepancy could appear as a result of using different sources and of possible errors and omissions.

## **10.7. Consolidation**

~~30.78~~<sup>30.77</sup> For analytical purposes, there is often interest in the relationship between net lending or net borrowing and the change in government liabilities. Attention to government liabilities usually ~~centres~~ centers on the amount owed to non-government units or abroad. There may be a substantial amount of liabilities incurred by one government unit and held by a second government unit. The government finance presentation consolidates all flows and stocks within each subsector and sector, and thus all asset and liability positions between units belonging to the same grouping are eliminated. This procedure still allows the separate identification of the debt of the general government sector, the central government subsector and the public sector, which are analytically useful.

~~30.79~~<sup>30.78</sup> Consolidation is a method of presenting statistics for a set of units as if they constituted a single unit. It involves eliminating transactions and reciprocal stock positions among the units that are being consolidated. Consolidation may be undertaken for any group of units, but it is particularly useful to consolidate the units within the general government sector and its subsectors. For example, assessing the overall impact of government operations on the total economy or the sustainability of government operations is more effective when the transactions between different levels of government are eliminated and only those

transactions that are with other sectors or non-residents remain. Consolidation is of particular relevance for transactions such as property income (in particular interest), current and capital transfers and transactions in financial assets and liabilities. For example, the consolidated figures on the ratio of revenue or expense to GDP are more useful for some purposes than the unconsolidated figures.

~~30.80~~30.79 In the SNA, consolidation is discouraged. Even in the government finance presentation, where consolidation is often useful, it takes place only within a single account where the matching revenue and expense entries appear. For this reason, consolidation adjustments do not affect balancing items. For example, a grant (or transfer) from a central government to a local government unit is consolidated by eliminating the expense from central government and the revenue from the local government, thus leaving the net operating balance of the general government sector unchanged.

~~30.81~~30.80 Conceptually, the nature of consolidation is to eliminate all flows and stock positions among the consolidated units, but practicality should be kept in mind. For example, it may be argued that transactions in the production account, such as output and intermediate consumption of goods and services, should not be consolidated. The decision about the level of detail employed in consolidation should be based on the policy usefulness of the consolidated data and the relative importance of the various types of transactions or stocks.

~~30.82~~30.81 Within a government finance presentation, the major transactions considered for consolidation, in probable order of importance, are:

- a. Current and capital transfers, such as central government grants to lower levels of government;
- b. Transactions in financial assets and liabilities, such as loans to other governments for policy purposes, acquisitions of government securities by social security units and debt forgiveness;
- c. Interest revenue and expense on intergovernmental holdings of financial assets and liabilities;
- d. Acquisitions and disposals of non-financial assets, including intergovernmental transactions in land, buildings and equipment;
- e. Taxes paid by one government unit or entity to another;
- f. Purchases and sales of goods and services between government units.

~~30.83~~30.82 Two types of transactions that appear to take place between two government units are never consolidated because they are re-routed in the SNA to other units. The first is that all employer social contributions, whether paid to social security or to government pension funds, are treated as being paid to the employee as part of compensationremuneration of employees, and then paid by the employee to the fund. The second is that all taxes withheld by government units from the compensationremuneration of their employees, such as pay-as-you-earn (PAYE) taxes, and paid to other governments should be treated as being paid directly by the employees. The government employer is simply the collecting agent in this case for the second government unit. However, taxes on gross payroll and labour force that are not treated as social contributions should be consolidated when they are significant and can be identified.

~~30.84~~30.83 Practical difficulties always arise with consolidation. For example, when a transaction to be consolidated is identified in the records of one unit, the corresponding transaction should appear in the accounts of the counterparty, ~~but~~. However, it may not be recorded there, it may be recorded in a different period, it may be recorded at a different value, or it may be classified as a different type of transaction. Such errors in the strict application of a quadruple accounting system may exist in relation to any transaction but become apparent when consolidation is attempted.

~~30.85~~30.84 Even if transactions between the subsectors of government are being consolidated when presenting the accounts for general government as a whole, they should not be eliminated for the accounts of each subsector considered separately.

## **4.8. Classification of the functions of government**

~~30.86~~30.85 A classification of expenditure transactions ~~on outlays~~ using the Classification of Functions of Government (COFOG) is integral to the government finance presentation. This functional classification shows the purpose for which outlays are undertaken. These purposes may differ significantly from the administrative arrangements of governments. For example, an administrative unit responsible for health services may undertake some activities with an educational purpose, such as training of medical professionals. A cross classification of the ~~transactions~~expenditure of government by both economic nature and according to functions ~~as shown, for example, in GFSM2001~~, in GFSM is encouraged.

## **4.2.D. Accounting issues particular to the general government and public sectors**

~~30.87~~30.86 The accounting rules of the SNA apply to general government and public sectors in the same way that they apply to all other sectors of the economy. However, due to the particular nature of the activities of government units, some additional guidance is useful to assist with the treatment of selected transactions. These topics are grouped under four headings:

- a. Clarification of the recording of taxes;
- b. Interaction ~~with non-resident~~ government-type authorities (including taxes paid to another authority);
- c. Issues related to debt;
- d. Interaction with the corporations sectors.

A separate section for each of these headings follows.

### **1. Clarification of the recording of taxes**

---

## Government issued permits

---

~~30.88~~30.87 Taxes are compulsory unrequited payments, in cash or in kind, made by institutional units to the general government exercising its sovereign powers or to a supranational authority. They usually constitute the major part of government revenue, up to 90 ~~per cent~~percent in some countries. Taxes are described as unrequited because, in most cases, the government provides nothing commensurate in exchange to the individual unit making the payment. However, ~~there are in some cases where~~, the government does provide something to the individual unit in return for ~~the~~ payment in the form of the ~~direct~~ granting of a permit, or ~~authorization. In this case, the payment is part of a mandatory process that ensures proper recognition of ownership or that activities are performed under the strict authorization by the law~~license. The borderline between when such payments are to be treated as a tax and when as the sale of a service or as the sale of an asset by the government requires ~~additional guidance~~explanation.

30.89 As noted in chapters 7 and 8 when discussing the difference between a tax and a fee for a service, the borderline is not always clear cut in practice. The following recommendations apply.

---

a. ~~The payment is recorded as a tax when a licence or a permit is automatically granted by the government as a mandatory condition to perform an activity or acquire an asset and when the government unit performs little or no work other than a minimum control of the legal capacity of the acquirer to receive the permit (for instance, to confirm the applicant has not been convicted of a crime). The payment of the fee in such a case is not commensurate with the control function that the government exercises.~~

---

b. ~~The payment is recorded as the purchase of a service when, for instance, issuing the licence or permit implies a proper regulatory function of the government by exercising control on the activity, checking the competence or qualifications of the persons concerned, etc. In such a case, the payment is taken to be proportion to the costs of producing the service for all or any of the entities benefiting from the services and is borne by those benefiting. Only if the payment is out of proportion to the costs of producing the services, is it treated as a tax.~~

---

30.88 One of the regulatory functions of governments is to forbid the ownership or use of certain goods, or the pursuit of certain activities, unless specific permission has been granted by issuing a permit or license for which a fee must be paid. Most mandatory payments for permits and licenses authorizing pursuit of an activity or ownership of a good can be considered unrequited, making them a tax rather than a fee for services. Usually, the primary beneficiary of the regulatory schemes that require these payments is society as a whole, not the individual unit making the payment. In other cases, the permit is simply issued automatically upon receipt of the payment. Furthermore, the payments to apply for a permit or license are frequently non-refundable if the permit or license is not granted.

30.89 Nevertheless, as noted in **paragraph 9.55**, in cases where the transaction involves a material service element and the payment amount is not disproportionate to the cost of supplying the service, recording a sale of services to the recipient of the permit or license may be appropriate.

30.90 **Chapter 17**27 discusses the case of licences issued by government in strictly limited numbers.

---

a. If the licence is not one to use a natural resource that qualifies as an asset and which the government controls on behalf of the community, then the payment for the licence is a tax. ~~Notwithstanding, if the licence is legally and practically transferable to a third party, it may still be classified as an asset in the category of contracts, leases and licences.~~

---

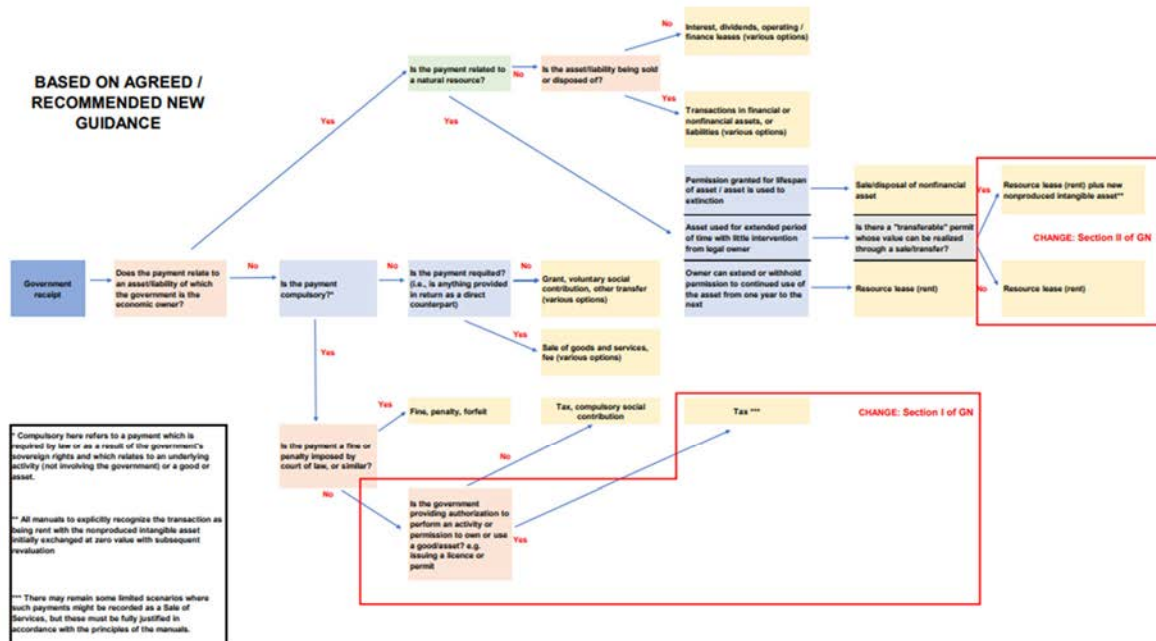

b. When the licence is to make use of a natural resource that qualifies as an asset and which the government controls on behalf of the community, all payments for the licence ~~are treated either as or~~ the acquisitionuse

of ~~an~~the natural resource asset ~~in the category of contracts, leases or licences or as the payment~~are treated as payments of rent. The conditions that need to be considered in deciding between the acquisition of an asset and the payment of rent are described in detail in ~~part 5 of~~ chapter ~~17~~27.

Permission to use a produced asset owned by government is treated as an operating or financial lease, as appropriate.

30.91 A decision tree on the classification of payments to government is shown in Figure 30.2. The decision tree summarizes the treatment of payments for permits and licenses, payments for use or ownership of natural resources, and types of payments to government.

**Figure 30.2. Decision Tree for Classifying Payments to Government**

## Accrual recording of taxes

**30.9130.92** Like all transactions in the system, government transactions should be recorded on an accrual basis. This is true on both the revenue side (for example, taxes and social contributions) and the expense side (for example, interest charges). Unless both parties to a transaction record their view of the transaction at the same point in time, the accounts do not balance.

**30.9230.93** For the government, recording revenue and claims when the underlying event occurs is particularly difficult ~~since government~~ if the government's recordings are ~~often~~ on a cash basis. This is especially the case for taxes. Further, when accrued taxes are calculated from assessments of taxes due, there may be a risk of over- or understatement of tax revenue. Since tax revenue is a crucial government finance aggregate, such an error must be avoided.

**30.9330.94** As explained in chapter 34, the period of time between the moment a tax or any distributive transaction is recorded as accruing in the non-financial accounts and the moment the payment is actually made is bridged by recording an account receivable or payable in the financial account. In cases where a prepayment covering two or more accounting periods is made to government, an account payable is recorded in the financial account of government for the amounts due in future periods. In effect this is a financial advance made to government by the payee. It is a liability of the government and an asset of the payee. This liability is extinguished as the amounts fall due in future periods.

**30.9430.95** The amount of taxes recorded as accruing recognizes that some taxes that may be due in principle are in practice unlikely to be collected. The alternative means of making the necessary adjustments are

described in paragraphs 8.58 to 8.59 to 9.61.58 to 8.59.8.59.

## Tax credits

30.9530.96 Tax relief can take the form of a tax allowance, an exemption, a deduction or a tax credit. Tax allowances, exemptions and deductions are subtracted from the tax base before the tax liability is computed. A tax credit is an amount subtracted directly from the tax liability due by the beneficiary household or corporation after the liability has been computed. Tax credits can sometimes be payable, in the sense that any amount of the credit that exceeds the tax liability is paid to the beneficiary. In contrast, some tax credits are non-payable (sometimes called wastable) and are limited to the size of the tax liability.

30.9630.97 In *Revenue Statistics* and ~~GFSM2001~~GFSM-, a tax relief that is embedded in the tax system is recorded as reducing the tax liability of the taxpayer and therefore as reducing government tax revenue. This is the case for tax allowances, exemptions and deductions, since they enter directly into the calculation of the tax liability. This is also the case for non-payable tax credits as their value to the taxpayer is limited to the size of their tax liability. ~~For payable tax credits, only the excess over the corresponding liability, which corresponds to an outlay by government, is shown as an expense.~~ However, when tax relief is granted in the form of payable tax credits, it should be recorded on a gross basis: the total amount of tax receivable should be recorded as tax revenue of government and the total amounts of payable tax credits should be recorded as expense.

30.97 ~~In contrast, in the SNA, the total amounts due as payable tax credits should be considered as expense and recorded as such at their total amount. In consequence, tax revenue should be recorded without any deduction for payable tax credits.~~

30.98 Treating payable tax credits in this way has no impact on the net borrowing or net lending of the general government, but has an impact on both the tax burden and the ratios of public expense or expenditure to GDP. ~~Because of the need to explain differences in presentation between different statistical systems, however, in the SNA the amounts of payable tax credits that are offset against tax liabilities should also be shown.~~

## 2. Transactions with other national, international and supranational organizations

30.99 Transactions may occur between government units and either international or supranational organizations, regarded as non-resident units. Even when government acts as the unit channelling funds to or from the non-resident unit, the transactions are recorded as taking place directly with the non-resident unit. Six cases may be considered:

- a. *Taxes*: Some taxes on products, such as import duties, excises and value added taxes, might be payable to a supranational organization because they are considered to be levied directly by the supranational organization.
- b. *Subsidies*: Any subsidies paid by a supranational organization directly to a resident producer are recorded as payable by the supranational organization rather than a resident government unit.
- c. *Current international cooperation*: This consists of current transfers in cash or in kind between the

governments of different countries or between governments and international organizations and includes specifically:

- Transfers between governments that are used by the recipients to finance current expenditures, including emergency aid after natural disasters; they include transfers in kind in the form of food, clothing, blankets, medicines, etc.;

- Annual or other regular contributions paid by member governments to international organizations (excluding taxes payable to supranational organizations);

- Payments by governments or international organizations to other governments to cover the salaries of those technical assistance staff who are resident in the country in which they are working and are employed by the host government.

d. *Miscellaneous current transfers*: These consist of payments to international or supranational authorities that are regarded as being compulsory but are not taxes.

e. *Capital transfers*: These include investment grants and other capital transfers, including the counterpart transaction of debt cancellation as a capital transfer payable and the counterpart of debt assumption as a capital transfer receivable.

f. *Financial transactions*: Some financial transactions, usually loans, may be recorded when granted by international organizations (for example, the World Bank and the International Monetary Fund) or granted to other governments.

## International membership dues

30.100 In ~~a few~~some cases, membership dues and subscription fees payable to international organizations may not be treated as transfers but as payments for a service, recorded on an accrual basis. Exceptionally, ~~and~~ when there is a possibility, even if unlikely, of repayment of the full amount, the payment may represent the acquisition of a financial asset.

## International assistance

30.101 International assistance sometimes takes the form of making goods, such as food and clothing or emergency equipment available following a natural disaster. In addition to the goods or services themselves, all costs identifiable with the delivery of the goods or services such as transportation to the foreign country, delivery within that country, the ~~compensation~~remuneration of government employees of the donating country to prepare the shipments or oversee their delivery, insurance and so forth should be included in the value of the transfer to the extent that these costs are met by the donor.

30.102 The prices of the goods or services in the receiving country might be quite different from the prices in the donor country. As a general principle, the value of the donation to the recipient should be regarded as equal to the cost of providing the assistance to the recipient. It follows that the prices of the donor country should be used as a basis for the calculation of the value of the donation.

30.103 When the goods and services and associated delivery charges are donated by government, NPISHs or households, the donated items are ~~negative~~excluded from final consumption ~~matching~~(and a current transfer ~~in kind~~is recorded. If the items are ~~provided~~donated by corporations, they are recorded as a current transfer ~~in cash~~ followed by a purchase of the goods by the recipient. In both cases the items involved are included in exports of the donor country and imports of the recipient country.

### **3. Debt and related operations**

#### **Debt**

30.104 Debt is a commonly used concept, defined as a specific subset of liabilities identified according to the types of financial instruments included or excluded. Generally, debt is defined as all liabilities that require payment or payments of interest or principal by the debtor to the creditor at a date or dates in the future. Consequently, all debt instruments are liabilities, but some liabilities such as shares, equity and financial derivatives are not debt. However, due to specific legal, institutional or practical arrangements some other definitions of debt may also exist. It is therefore useful in all cases to clearly identify the definition of debt according to the instruments included.

30.105 Debt operations are often used by government as a means of providing economic aid to other units. The general principle for any cancellation or assumption of debt of one unit by another unit made by mutual agreement is to consider that there is a voluntary transfer of wealth between the two units. This means that the counterpart transaction of the liability assumed or of the claim cancelled is a capital transfer.

#### **Debt reorganization**

~~30.106 There are four main types of debt reorganization:~~

30.106 Debt reorganization (also referred to as debt restructuring) is an arrangement involving both the creditor and the debtor (and sometimes third parties) that alters the terms established for servicing an existing debt. Governments can be involved in debt reorganization as debtors, creditors, or guarantors. There are four main types of debt reorganization:

a. Debt forgiveness. A reduction in the amount of, or the extinguishing of, a debt obligation by the creditor via a contractual arrangement with the debtor.

b. Debt rescheduling or re-financing. A change in the terms and conditions of the amount owed, which may result or not in a reduction in burden in present value terms.

c. Debt conversion. ~~The and debt prepayment. In a debt conversion, the~~ creditor exchanges the debt claim

for something of economic value; other than another debt claim, on the same debtor. This includes debt-for-equity swaps and debt ~~prepayment~~ for-development swaps among other arrangements.

- 
- d. Debt assumption and debt payments on behalf of others when a third party is also involved.

### *Debt forgiveness (or debt cancellation)*

---

- 30.107 Debt forgiveness is defined as the voluntary cancellation of all or part of a debt obligation within a contractual arrangement between a creditor and a debtor. Debt forgiveness is distinguished from debt write-off by the agreement between the parties and the intention to convey a benefit, rather than unilateral recognition by the creditor that the amount is unlikely to be collected. Debt forgiven may include all or part of the principal outstanding, inclusive of any accrued interest arrears (interest that fell due in the past) and any other interest costs that have accrued. Debt forgiveness does not arise from the cancellation of future interest payments that have not yet fallen due and have not yet accrued.
- 30.108 Debt forgiveness is recorded as a capital transfer received by the debtor from the creditor at the time specified in the agreement that the debt forgiveness takes effect with a repayment of the debtor's liability in the financial account and a matching receipt by the creditor. In the balance sheet, the debtor's liability and creditor's asset are reduced by the amount of debt that is forgiven. Valuation of the amount of the debt forgiven is at market prices for flows and stocks, except for loans where the nominal value is used.

### *Debt rescheduling and refinancing*

---

- 30.109 Debt rescheduling (or refinancing) is an agreement to alter the terms and conditions for servicing an existing debt, usually on more favourable terms for the debtor. Debt rescheduling involves rearrangements on the same type of instrument, with the same principal value and the same creditor as with the old debt. Refinancing entails a different debt instrument, generally at a different value and may be with a creditor different than that from the old debt.
- 30.110 Under both arrangements, the debt instrument that is being rescheduled or refinanced is considered to be extinguished and replaced by a new debt instrument with the new terms and conditions. If there is a difference in value between the extinguished debt instrument and the new debt instrument, ~~part of the same type, the difference~~ is a type of debt forgiveness by government and a capital transfer is ~~necessary~~ recorded to account for the difference.
- 30.111 *Debt rescheduling* is a bilateral arrangement between the debtor and the creditor that constitutes a formal deferment of debt-service payments and the application of new and generally extended maturities. The new terms normally include one or more of the following elements: extending repayment periods, reductions in the contracted interest rate, adding or extending grace periods for the repayment of interest and principal, fixing the exchange rate at favourable levels for foreign currency debt, and rescheduling the payment of arrears, if any.
- 30.112 The treatment for debt rescheduling is that the existing contract is extinguished and a new contract created. The applicable existing debt is recorded as being repaid and a new debt instrument (or instruments) of the same type and with the same creditor is created with the new terms and conditions.

30.113 The transaction is recorded at the time agreed by both parties ~~record the change in terms in their books,~~ and ~~is valued~~ at the value of the new debt.

---

30.114 *Debt refinancing* involves the replacement of an existing debt instrument or instruments, including any arrears, with a new debt instrument or instruments. It can involve the exchange of the same type of debt instrument (such as a loan for a loan), or different types of debt instruments (such as a loan for a bond). For instance, ~~the~~ public sector unit may convert various export credit debts into a single loan. ~~Also, debt refinancing can be said to have taken place when a debtor exchanges or exchange~~ existing bonds for new bonds through exchange offers given by its creditor (rather than a change in terms and conditions).

---

30.115 The treatment of debt refinancing transactions is similar to debt rescheduling to the extent that the debt being refinanced is extinguished and replaced with a new financial instrument or instruments. However, unlike in rescheduling, the old debt is extinguished at the value of the new debt instrument except for non-marketable debt ~~owed (e.g., a loan) owed to official creditors.~~ The balance sheet reflects the transactions extinguishing the old debt instrument and the creation of the new debt instrument along with any valuation change -(the difference between the value of the old and new debt instruments) recorded in the revaluation account.

### *Debt conversion*

---

30.116 ~~A~~ Debt conversion (swap) is an exchange of debt, typically at a discount, for ~~a nondebt claim (such as equity swap), or for counterpart funds that can be used to finance a particular project or policy. An example is a debt-for-equity swap, which~~ occurs when a creditor agrees to replace a debt owed to it ~~by an~~ with equity ~~security~~. For example, the government may agree with a public enterprise to accept an increase in its equity stake in the public enterprises instead of making a loan. If there is a difference in value between the extinguished debt instrument and the new equity instrument, it is a type of debt forgiveness by government and a capital transfer is necessary to account for the difference.

### *Debt assumption*

---

30.117 *Debt assumption* occurs when one unit assumes responsibility for another unit's outstanding liability to a creditor. When a government assumes a debt, in most instances the counterpart transaction of the new government liability is a capital transfer in favour of the defaulting debtor. However, if the government acquires an effective legal claim against the defaulting unit and there is a realistic probability that the claim will be paid, the government may record, as the counterpart transaction of its new liability, the acquisition of a financial asset equal to the present value of the amount expected to be received. If this amount is equal to the liability assumed, no further entries are required. If the amount expected to be recovered is less than the liability assumed, the government records a capital transfer for the difference between the liability incurred and any asset acquired. Similarly, if a government has its debt assumed by another government, then it ~~records~~ might record a capital transfer receivable, a new debt to the assuming government unit, or a combination of the two.

---

30.118 Debt assumption frequently occurs when a government guarantees a debt of another unit and the guarantee is called (or activated). The treatment of the guarantee itself is described below.

---

30.119 *Debt payments on behalf of others* are similar to debt assumptions, but the unit making the payments does not assume the entire debt. The transactions recorded are similar to those described under debt

forgiveness.

## Other issues related to debt re-organization

- 30.120 *Debt write-offs* refer to unilateral reductions by a creditor in the amount owed to it, usually when a creditor concludes that a debt obligation has no value or a reduced value because part or all of the debt is not going to be paid. Frequently the debtor is bankrupt or has disappeared. An other change in the volume of assets is used to record the write-off. Unlike the cases of debt assumption and debt forgiveness, no capital transfer is recorded and therefore there is no impact on net lending or borrowing of government.
- 30.121 *Debt arrears* occur when a debtor misses an interest or principal payment. The debt instrument will not normally change, but knowing the amount of debts in arrears can provide important information. When feasible and important, therefore, each category of debt should be divided into those instruments that are in arrears and those not in arrears.
- 30.122 *Debt defeasance* allows a debtor (whose debts are in the form generally of debt securities and loans) to remove certain liabilities from the balance sheet by pairing irrevocably assets of equal value to the liabilities. Defeasance may be carried out either by placing the paired assets and liabilities in a trust account within the institutional unit concerned, or by transferring the paired assets and liabilities to another institutional unit. In the former case, there are no transactions with respect to defeasance and the assets and liabilities should not be excluded from the balance sheet of the unit. In the latter case, the assets and liabilities in question are moved to the balance sheet of second unit as long as this unit is recognized as an institutional unit in the SNA. Often the unit to which the paired assets and liabilities may be moved is ~~an SPE~~ a special purpose unit. The conditions under which ~~an SPE~~ a special purpose unit is considered to be an institutional unit are described in paragraphs 4.55 to 4.67. ~~4.55 to 4.67~~ 4.55 to 4.67. If the ~~SPE~~ special purpose unit is purely passive it is not considered to be an institutional unit and the assets and liabilities concerned do not move off-balance sheet.
- 30.123 Debt issued on concessional terms. ~~There is no precise definition of concessional loans, but it is generally accepted that they occur~~ occurs when units lend to other units ~~and that a~~ contractual interest rate that is intentionally set below the market interest rate that would ~~otherwise~~ normally apply. The degree of concessionalism can be enhanced with grace periods, and frequencies of payments and a maturity period favourable to the debtor. Since the terms of a concessional loan are more favourable to the debtor than market conditions would otherwise permit, concessional loans effectively include a transfer from the creditor to the debtor.
- 30.124 Loans with concessional interest rates ~~to a foreign government~~ could be seen as providing a stream of current transfers equal to the difference between imputed interest payments based on the applicable market rate of interest and the actual interest and the market equivalent interest. ~~If payments required under the terms of the loan. However, for practical reasons, such a transfer were recognized, it would usually be current transfers are only recorded as current in cases of an employer lending to employees at below-market rates of interest. In the cases of loans provided by governments and international cooperation, and the interest recorded would be adjusted by the same organizations that contain a gift or transfer element, the difference between the amount. However, the means of incorporating the impact within the SNA and international accounts have not been fully developed, although various alternatives have been advanced. Accordingly, until the appropriate treatment of borrowed on concessional debt is agreed, information on concessional debt should be provided terms (the face value of the loan) and the market value of loan at the time of origination may be presented as a capital transfer to the borrower in supplementary tables.~~

- 30.125 Further details on the recording of debt operations can be found in ~~GFSM2004~~[GFSM](#), the [Eurostat Manual on Government Debt and Deficit and Debt, the Public Sector Debt Statistics Guide for Compilers and Users](#), the External Debt [Statistics Guide for Compilers and Users](#), and [Appendix 2](#) of ~~BPM6~~[BPM7](#).

## Government guarantees

- 30.126 Three types of guarantees are recognized in the SNA, standardized guarantees, guarantees that meet the definition of a financial derivative and one-off guarantees. The recording of standardized guarantees (for government and other units offering such guarantees) is described in ~~part 3 of~~ chapter ~~47~~[25](#).
- 30.127 ~~————~~Guarantees that meet the definition of financial derivatives are those that are actively traded on financial markets, such as credit default swaps. The derivative is based on the risk of default of a reference instrument and so is not actually linked to an individual loan or bond. They have no effect on the net lending or borrowing of government.
- 30.128 One-off guarantees exist where the conditions of the loan or the security are so particular that it is not possible for the degree of risk associated with the loan to be calculated with any degree of accuracy. In most cases, the granting of a one-off guarantee is considered a contingency and is not recorded as a liability for the guarantor. Payments under a one-off guarantee are recorded when the call on the guarantee is made or when the fact that such a call will be made is very well established. As an exception, one-off guarantees granted by governments to corporations in certain financially distressed situations and with a very high likelihood to be called are treated as if these guarantees were called at inception. A particular case in point is a bailout by government, which is discussed below.
- 30.129 The activation of a one-off guarantee is treated in the same way as a debt assumption. The original debt is liquidated and a new debt is created between the guarantor and the creditor. In most instances, the guarantor is deemed to make a capital transfer to the original debtor, unless the guarantor acquires an effective claim on the creditor, in which case it leads to the recognition of a financial asset (~~a liability of the debtor~~[the liability of the creditor towards the guarantor](#)). [In exceptional cases where there is a very high likelihood that the guarantee will be called \(such as one-off guarantees granted by governments to corporations in financial distress\), the one-off guarantee may be treated as called at inception.](#)
- 30.130 The activation of a guarantee may or may not require repayment of debt at once. The accrual principle for time of recording requires that the total amount of debt assumed is recorded at the time the guarantee is activated and the debt assumed. Repayments of principal by the guarantor (the new debtor) and interest accruals on the assumed debt are recorded as these flows occur.

## Securitization

- 30.131 Securitization occurs when a unit, named the originator, conveys the ownership rights over financial or non-financial assets or the right to receive specific future flows, to another unit, named the securitization unit. In return, the securitization unit pays an amount to the originator from its own source of financing. The securitization unit is often ~~an SPE~~[a special purpose unit](#). The securitization unit obtains its own financing by issuing [debt](#) securities using the assets or rights to future flows transferred by the originator as collateral. Government units have made widespread use of this source of ~~finance~~[financing](#).

30.132 The first case involving government to be considered is when the securitization comprises the sale (or the transfer) of an asset. (In the SNA, a stream of future tax receipts is not recognized as a government asset that could be used for securitization.) The key question for how to record the transaction properly is to determine whether the transfer of the asset is a sale of an existing asset to the securitization unit or a way to borrow using possible future flows of revenues as collateral. In order to be treated as a sale, the asset must already appear in the balance sheet of the government and there must be a full change of ownership to the securitization unit as evidenced by the transfer of the risks and rewards linked to the asset. The following factors must also be considered:

- a. To be recorded as a sale, the purchase price must be equal to the current market price.
- b. If the government, as the originator, guarantees repayment of any debt related to the asset incurred by the securitization unit, it is unlikely that all of the risks associated with the asset have been transferred.

30.133 The second case involving government is the securitization of future revenue flows. In the SNA, a stream of future incomes is not recognized as an asset. In most of these cases, it is not the rights to the income that are used as collateral, but the obligation of the government to use a sufficient amount of the future income to repay the borrowing in full. If more income is earned than is needed to repay the borrowing, the excess is retained by the government. Because receipts of future income are uncertain, “rights” to considerably more income than is necessary to repay the borrowing of the securitization unit are usually used as collateral. The amount received by the government as the originator is treated as borrowing, usually in the form of a loan.

### **Government assumption of pension liabilities**

30.134 On occasion, large one-off transactions may occur between a government and another unit, usually a public corporation, linked to pension reforms or to privatization of public corporations. The goal may be to make a public corporation competitive and financially more attractive by removing existing pension liabilities from the balance sheet of the public corporation. This goal is commonly achieved by the government assuming the liability in question in exchange for a cash payment of the same value. If the cash payment is not equal in value to the liability incurred, a capital transfer is recorded for the difference.

## **4. Relations of general government with corporations**

### **Earnings from equity investment**

30.135 A government unit has a close relationship with any public corporation or quasi-corporation that it controls. Despite this close relationship, flows related to the equity investment between a government unit and its controlled corporation are treated in the same way as flows related to equity investment between any corporation and its owners. An equity investment is the action by economic agents of placing funds at the disposal of corporations. The amounts invested, described as equity capital, are part of the own funds of the corporation and the corporation has a large degree of freedom in the way in which they are used. In return, the owners receive shares or some other form of equity securities. These financial assets represent property rights on corporations and quasi- corporations and entitle the holders to:

- a. A share of any dividends (or withdrawals of income from quasi-corporations) paid at the discretion of the corporation but not to a fixed and predetermined income, and
- b. A share in the net assets of the corporation in the event of its liquidation.

## Dividends versus withdrawal of equity

30.136 It is important to distinguish between the return of the equity investment by the corporation to its owner and the payment of income in the form of dividends. Only regular distributions from the entrepreneurial income are recorded as property income either as dividends or withdrawals of income from quasi-corporations. Large and irregular payments, based on accumulated reserves or sale of assets are recorded as a withdrawal of equity.

30.137 However, it is encouraged to produce, as supplementary items, estimates applying an alternative treatment of earnings from equity investment in corporations in which the retained earnings of corporations are recorded as distributed to the shareholders and reinvested by them. This alternative treatment is also relevant for public corporations.

## Disposal of assets

~~30.137~~30.138 The sale of non-financial assets owned by public corporations, such as buildings and land, does not by itself constitute privatization and is recorded in the capital account of the corporations sector as disposals of fixed assets or other non-financial assets. However, if the public corporation sells assets and then surrenders the proceeds of such a sale to general government, this is recorded as a withdrawal of government's equity in the corporation. A withdrawal of equity is also recorded if the public corporation disposes of a financial asset and surrenders the proceeds to government.

## Acquisition of equity, capital transfers and subsidies

~~30.138~~30.139 Subsidies are current transfers, usually made on a regular basis, from government to ~~corporations~~enterprises designed to influence their levels of production, the prices at which their outputs are sold or the remuneration of the ~~corporations~~enterprises. Payments to public corporations on a large and irregular basis (often called "capital injections" in the media) are not subsidies. They are treated as either a capital transfer or the acquisition of equity:

- a. Payments to cover cumulated losses over two or more years arising as a result of public policy purposes should be recorded as a capital transfer.
- b. A payment made in a commercial or competitive context may be treated as an acquisition of equity. This should be limited to cases where the government is acting similarly to a private shareholder in that it has a valid expectation of a cash return in the form of future property income. In this case, the corporation will probably issue new shares to the government and enjoy a large degree of freedom over how the funds provided are used.

Treating the payments as the acquisition of equity depends on evidence of the corporation's profitability and its ability to pay dividends in future.

## Privatization

~~30.139~~30.140 Privatization is usually understood to consist of the sale of shares or other equity held by government in a public corporation to other units. Often these other units are outside the public sector but they need not be; for example, a public corporation may buy shares in a unit newly separated from government. Such sales are purely financial transactions, recorded in the financial account of the SNA. The assets owned by the public corporation continue to belong to the corporation; it is the ownership of the corporation itself, as represented by the ownership of the equity in it, that changes hands. In effect, the government's claim on the public corporation reduces because government exchanges shares or equity in the public corporation for cash or other financial assets. The cost of any financial services that government must purchase to achieve the sale are treated as an expense that should be recorded as intermediate consumption by general government in the SNA.

~~30.140~~30.141 Privatization may be organized in more complicated institutional arrangements. For instance, some or all of the non-financial assets of a public corporation may be sold by a public holding company, or other public agency, controlled by a government and all or part of the proceeds paid to the government. In such cases, the public corporation will record the disposal of non-financial assets in the capital account, while the payment to the government of the proceeds from the sale is recorded as a withdrawal of equity.

~~30.141~~30.142 The case where the privatization is arranged via a restructuring agency is discussed in paragraphs 22.4730.45 to 22.5030.48

## Nationalization

~~30.142~~30.143 Nationalization is a process whereby government takes control of specific assets or an entire corporation, usually by acquiring the majority or the whole stake in the corporation. The recording of flows differs according to the way the government takes control.

a. *Appropriation or confiscation*: the change in ownership of assets is not the result of a transaction made by mutual agreement. There is no payment to the owners (or the compensation is not commensurate with the fair value of the assets). The difference between the market value of the assets acquired and any compensation provided is recorded as an uncompensated seizure in the other changes in the volume of assets account.

b. *Purchase of shares*: the government buys all or some of the shares in the corporation at a price that is the market price or very close to it. There is usually a legal context for the transaction which ensures that it is made by mutual agreement, even though the former owner may have little choice whether or not to accept the offer, or to negotiate the price. The purchase of shares is a financial transaction recorded in the financial account.

## Bailouts

~~30.143~~30.144 A bailout is a term meaning a rescue from financial distress. It is often used when a government unit provides either short-term financial assistance to a corporation to help it survive a period of financial difficulty or a more permanent injection of financial resources to help recapitalize the corporation. A bailout may in effect constitute another means of nationalization if the government acquires control of the corporation it is bailing out. Bailouts of financial institutions are particularly noteworthy. Bailouts are likely to involve highly publicized one-time transactions involving large amounts and are therefore easy to identify.

~~30.144~~30.145 Intervention of general government may take various forms. For instance:

- a. A government might provide equity financing or a loan on exceptionally favourable terms.
- b. A government might purchase assets from the enterprise to be assisted for prices greater than their true market value: or accept less than a fair price to assume its liabilities.
- c. A government might create a special purpose ~~entity~~unit or other type of public body to finance or to manage the sales of assets or liabilities of the enterprise to be assisted.

~~30.145~~30.146 In most of these cases, the assistance provided by government to the unit suffering financial distress is recorded as a capital transfer. In determining the magnitude of the capital transfers, the following points need to be taken into account.

- a. If the government buys assets from the enterprise to be assisted, the amount paid will normally be more than the true market price of the assets. The purchase of assets other than loans should be recorded at the actual market price and a capital transfer should be recorded for the difference between the market price and the total amount paid.
- b. Governments often buy loans from financial institutions during a bailout. Unless a loan becomes tradeable and is traded with established market value, it is always recorded in the SNA at nominal value. Only if a market for the loans develops and the loans are regularly traded ~~there~~ are they reclassified as securities and recorded at market value.
- c. When a government buys a loan at nominal value when the fair value is much less, no capital transfer for the difference in value is recorded. However, if there is reliable information that some loans are irrecoverable, their value is reduced to zero as an other volume change in the balance sheet of the corporation and a capital transfer should be recorded from government to the corporation for their former nominal value. If there is some possibility that some part of the loan may be recoverable in the future, the loans are reclassified (at their zero value) from the balance sheet of the corporation to that of the government at the time the capital transfer is recorded. If the value of the loans subsequently increases, this is shown as a revaluation item in the government's balance sheet.
- d. As part of a bailout, government may extend the range of guarantees it is prepared to offer. These guarantees should be recorded as described above in paragraphs 30.127 to 30.131 according to whether this is a one-off guarantee or part of a standardized guarantee scheme.

~~22.126 to 22.130 according to whether this is a one-off guarantee or part of a standardized guarantee scheme.~~

~~30.146~~30.147 If a public institutional unit is created by government ~~simply~~solely to assume management of the bailout, the unit should be classified in the general government sector. If the new unit has other functions and the bailout is a temporary task, its classification as a government unit or a public corporation is made following the general rules as described in the section above on restructuring agencies. Units that purchase financial assets from distressed financial corporations with the objective of selling them in an orderly manner cannot be considered financial intermediaries. If the unit has been created by government for this specific task, it is classified in the general government sector.

30.148 It is usually assumed that the controlling government will provide a bailout to the public corporations it controls if necessary. This implicit guarantee of the liabilities of a controlled public corporation means that the public corporation's negative net worth will become part of the net worth of the controlling government if it fails (or, possibly, part of the net worth of another public corporation controlled by the same government that is used to conduct the bailout). A controlling government's equity in a corporation that it controls can therefore be negative. Negative equity positions in controlled public corporations should be allowed to pass through to the balance sheet of the controlling government rather than recorded as zero. In addition, the reporting of negative equity positions as supplementary "of which" items is encouraged. The same treatment of negative net equity positions also applies to the central bank.

## **Restructuring, mergers and reclassifications**

~~30.147~~30.149 When a public corporation is restructured, financial assets and liabilities may appear or disappear reflecting new financial relationships. These changes are recorded as changes in sector classification and structure in the other changes in the volume of assets and liabilities account. An example of such a restructuring is when a corporation is split into two or more institutional units and new financial assets and liabilities are created.

~~30.148~~30.150 The purchase of shares and other equity of a corporation as part of a merger, on the other hand, is to be recorded as a financial transaction between the purchasing corporation and the previous owner.

~~30.149~~30.151 Any change in the classification of assets and liabilities not related to restructuring or changes in sector classification is recorded as a change in the classification of assets or liabilities in the other changes in the volume of assets and liabilities account.

## **Transactions with the central bank**

~~30.150~~30.152 It is appropriate to begin by recalling the definition of the central bank and associated explanations from chapter 45. The central bank is the national financial institution that exercises control over key aspects of the financial system. In general, the following financial institutions are classified in this subsector:

- a. The national central bank, including where it is part of a system of central banks; and

- b. Currency boards or independent currency authorities that issue national currency that is fully backed by foreign exchange reserves.

- c. Central monetary agencies of essentially public origin (for example, agencies managing foreign exchange or issuing bank notes and coin) that keep a complete set of accounts but are not classified as part of central government. Supervisory authorities that are separate institutional units are not included with the central bank but are included with financial auxiliaries.

As long as the central bank is a separate institutional unit, it is always allocated to the financial corporations sector even ~~if though~~ it is primarily considered as a non-market producer.

~~30.151~~30.153 While the bank may be legally independent of government, it is charged with carrying out government policy under the legislation establishing it. The central bank is always treated as being controlled by government and is included in the financial corporations sector as a public corporation. It is the single exception to the rule that a unit whose output is primarily non-market is not to be classified as a corporation.

~~30.152~~30.154 Two types of payments by the central bank to the government require clarification:

- a. Payments made on a regular basis, usually in the form of dividends, based on the current activity of the central bank (such as managing foreign exchange reserves). These payments are recorded as dividends so long as they are not abnormally higher than the sum of net interest and net commissions receivable by the bank. Amounts in excess of this sum are to be recorded as a withdrawal of equity.
- b. Exceptional payments following sales or revaluation of reserve assets. These payments should be recorded as a withdrawal of equity. The rationale is that these assets are being managed as the economic property of the nation and not of the bank itself. Their valuation affects the equity liability of the central bank and the equity assets of the government. Holding gains on the reserve assets (assets of the central bank) have a counterpart in the equity liability of the central bank and the equity assets of the central government.

~~30.153~~30.155 The measurement of output of the central bank is described in paragraphs 7.165-7.169. ~~6.151 to 6.156. As part of government policy, the central bank may pay interest on deposits at artificially high or low rates. The treatment of interest payments in this case is described in paragraphs 7.122~~ 8.151 to 7.126 ~~8.155. 151 to 7.156.~~

## Public-private partnerships

~~30.154~~30.156 Public-private partnerships (PPPs) are long-term contracts between two units, whereby one a private unit (usually a private enterprise but occasionally a private NPI) and a public unit for the provision of a public asset or set of assets and related services in which the private party acquires or builds, or refurbishes an asset or set of assets, operates it for period and then hands the asset over to a second unit. Such the asset for the contract period and bears significant risk and management responsibility. There are many types of PPP arrangements are usually between a private enterprise and government but other combinations are possible, with a public corporation as either party or a private NPI as the second party. These schemes are described variously as Public-Private Partnerships (PPPs), Private Finance Initiatives (PFIs), Build-Own-Operate-Transfer schemes (BOTs), Build-Own-Operate-Transfer schemes (BOOTS), Design-Build-Operate schemes (DBOs), Design-Build-Finance-

Operate schemes (DBFOs), concessions, and so on. The basic principles of all are the same and are treated the same way in the SNA.

30.157 Governments engage in PPPs for a variety of several reasons, including the hope that private management may lead to more efficient production and that, the desire to defer or spread payment obligations, and to benefit from access to a broader range of financial financing sources can be obtained. In, During the contract period, the PPP contractor operates the asset and assumes the associated risk and has the economic ownership. Once The legal ownership of the assets during the contract period depends on the terms of the contract and the applicable laws. Usually, once the contract period is over, the asset is transferred to the public sector, leaving the government has with both economic and legal ownership. It is not easy to establish which unit is the legal (An asset's economic owner of an asset during the contract period or how the implicit transactions when can differ from its economic ownership changes should be recorded. There may be an advance agreement on the timing of the transfer of legal owner, as economic ownership part way through the service lives of the assets, under agreed terms that do not reflect market prices in the SNA is based on who bears the majority of the risks and rewards, and economic ownership in the SNA may also differ from ownership of PPP assets in business accounts based on control over the assets).

30.155 PPP contracts vary in their terms concerning the operation and maintenance of the assets. In consequence, some actual transactions may have to be partitioned during the contract period and the disposition of the assets at its end, and in the standards for the price, quality and volume of the services to reveal their true economic character.

30.158 PPPs vary greatly be supplied. A general description that includes the most common type of arrangement is as follows. A for a private enterprise agrees to acquire a complex of fixed assets and then to use those assets together with other production inputs to produce services. Those services may be delivered to the government, either for use as an input to its own production (for example, motor vehicle maintenance services) or for distribution to the public without payment (for example, education services), in which case the). If the services are to be distributed to the public the government will make performance-based periodic payments during the contract period. The private enterprise expects to recover its costs linked to the asset's availability and earn an adequate rate the delivery of return on its investment from those payments the related services. Alternatively, in a concession arrangement, the private enterprise may builds or acquires assets, then uses those assets to sell the services to the public (for example, a toll road), with the price regulated). In either case, the payments to be received by the government but set at a level that the private enterprise expects will allow it are expected to recover cover its costs and allow it to earn an adequate rate of return on its investment. At the end of the contract period, the government may gain legal and economic ownership of the assets, possibly without payment.

30.156 30.159 There can be many variations in PPP contracts regarding the legal ownership of the asset during the contract period, the disposition of the assets at the end of the contract, the required operation and maintenance of the assets during the contract, the price, quality and volume of services produced and so forth. At the end of the contract period, the government may gain legal and economic ownership of the assets without payment.

30.157 30.160 The Even though the private enterprise is responsible for constructing or acquiring the fixed assets, although the acquisition is often aided the financing may be provided by the backing of the government. The or facilitated by a government guarantee, and the contract may require, however, that the assets meet the design, quality and capacity specified by the government. The contract may also require that the assets be used in the manner specified by the government to produce the services required by the contract and be maintained in accordance with standards specified by the government. Furthermore, the assets typically have longer service lives much longer than the contract period, so that the government will control the assets, bear the risks and receive the rewards for a major significant portion of the assets' service lives. Thus, it frequently is not obvious whether the private enterprise or the government controls the assets over their service lives or will bear bears the majority of the risks and reap reaps the majority of the rewards.

30.158 30.161 As with operating and financial leases, the economic owner of the assets related to of a PPP is

determined by assessing which unit bears the majority of the risks and which unit is expected to receive a majority of the rewards of the assets. The factors ~~that need to be considered~~ consider in making this assessment can be broadly divided into two groups, those associated with acquiring the asset and those associated with using it in production. Some of the risks associated with acquiring the asset are:

- a. The degree to which the government controls the design, quality, size and maintenance of the assets;
- b. Construction risk, which includes the possibility of additional costs resulting from late delivery, not meeting specifications or building codes and environmental and other risks requiring payments to third parties.

Some of the risks associated with using the asset in production are:

- a. Supply risk, which covers the degree to which the government is able to control the services produced, the units to which the services are provided and the prices of the services produced;
- b. Demand risk, which includes the possibility that the demand for the services, either from government ~~or, or from the public at large in the case of a concession arrangement, is higher or lower than expected~~  
~~from the public at large in the case of a paying service is higher or lower than expected;~~
- c. Residual value and obsolescence risk, which includes the risk that the value of the asset will differ from any price agreed for the transfer of the asset to government at the end of the contract period;
- d. Availability risk, which includes the possibility of additional costs or the incurrence of penalties because the volume and/or quality of the services do not meet the standards specified in the contract.

~~30.159~~ 30.162 The relative importance of each factor is likely to vary with each PPP. It is not possible to state in advance a set of prescriptive rules that will be applicable to every situation ~~in a satisfactory way~~. The provisions of each PPP must be evaluated in order to decide which unit is the ~~legal~~ economic owner.

~~30.160~~ 30.163 Likewise, the complexity and variety of PPP contracts preclude the enumeration of detailed rules governing the transactions to be recorded concerning the control and use of the assets. Instead, ~~all of~~ the facts and circumstances of each contract should be considered, and ~~then~~ an accounting treatment should be selected that best brings out the underlying economic relationships. There are, however, a few common difficulties.

— If the private enterprise is assessed as being the legal owner during the contract period and if, as usual, the government obtains legal and economic ownership at the end of the contract without an explicit payment, a transaction must be recorded for the government's acquisition of the assets.

30.164 One general approach is for the government gradually to build up a financial claim and the private unit gradually to accrue a corresponding liability such that the value of both is expected to be equal to the residual value of the assets at the end of the contract period. At the end of the contract period, the government records the acquisition of the asset and the disappearance of the financial claim, and the private unit records the disposal of the asset and the disappearance of the liability for the claim. Implementing this approach requires

existing monetary transactions to be ~~rearranged~~partitioned or new transactions to be ~~constructed~~imputed using assumptions about expected asset values and interest rates.

~~30.161~~30.165 ~~An~~A simpler alternative ~~approach~~ is to record the change of legal and economic ownership as a capital transfer. ~~The capital transfer occurring in the same period as the change in ownership. This~~ approach does not reflect the underlying economic reality as well, but data limitations, uncertainty about the expected residual value of the assets, and contract provisions allowing various options to be exercised by either party could make recording a capital transfer acceptable on pragmatic grounds.

~~30.162~~30.166 If the government is assessed as being the ~~legal~~economic owner of the PPP asset during the contract period but does not make any explicit payment at the beginning of the contract, ~~a transaction~~transactions must be imputed to cover the acquisition. ~~The most common suggestion is that the~~ of the asset. An acquisition ~~be made~~ via ~~an imputed~~a financial lease may be imputed because of the similarity with actual financial leases. The ~~details of the~~ implementation of ~~that choice, however, depends~~this approach depend on the specific contract provisions, ~~how they are interpreted~~ and possibly other factors. ~~For example, but in general, a loan could be structured as financial lease is imputed and. If there are actual government payments to the private unit, if they exist, could be partitioned so that a portion~~portions of each payment ~~represents repayment of the go towards imputed payments of principle and interest on the loan. If there are no actual government payments, then non-monetary transactions could be constructed (as in a concession arrangement), part of the payments from the public for use of the asset may be re-routed through the government, with the imputed revenue being used by the government for imputed payments of principle and interest on the loan payments.~~

## **13.E. The public sector presentation of statistics**

~~30.163~~30.167 As described in section B, the public sector includes all resident institutional units controlled directly or indirectly by resident government units. In other words, the public sector consists of all units of the general government sector plus all resident public corporations.

~~30.164~~30.168 Statistics for the public sector can be presented both within the sequence of economic accounts for institutional units and sectors or within the same government finance framework as described in section C of this chapter, depending on the use to be made of the statistics.

~~30.165~~30.169 With either method of presentation, it is useful to show both subsectors of the public sector and the entire public sector, with the total public sector statistics shown both unconsolidated and consolidated. For example, one column might have the statistics for the general government sector, a second column for the aggregate of all public corporations and a third column would have the unconsolidated totals for the entire public sector. Depending on the flows involved, a fourth column could show the amounts to be eliminated by consolidation and a fifth column could show the consolidated totals for the entire public sector.

~~30.166~~30.170 Not all flows need to be consolidated for the public sector. Because the public sector is a mixture of market and non-market producers, most components of revenue and expense will have limited economic meaning for the public sector. Elements of the financial account and the balance sheet are the most likely candidates to be consolidated.

~~30.167~~30.171 The same balancing items as stressed for the general government sector are likely to be important for the public sector. The public sector net operating balance (or saving in the SNA sequence of economic accounts) will indicate trends in net worth resulting from the public sector's current operations. This is

particularly useful if there are public corporations operating at significant losses.

~~30.168~~30.172 Net lending or net borrowing for the total public sector is ~~known as an indicator of~~ the public sector borrowing requirement. Net lending indicates the net financing supplied to either the rest of the economy or the rest of the world; net borrowing indicates net financing obtained by the public sector from either the rest of the economy or the rest of the world.

~~30.169~~30.173 The balance sheet provides information ~~on~~ net worth, determined as the value of total assets less ~~total~~ liabilities, and financial net worth, determined as the difference between the value of total financial assets and ~~the~~ total liabilities. The latter is often cited because of the public sector's influence on the financial system and because it is often difficult to value government-unique non-financial assets.

## **F. Links to International Public Sector Accounting Standards (IPSAS)**

30.174 The International Public Sector Accounting Standards (IPSAS) are a comprehensive set of accounting standards for public sector entities that meet the following criteria:

- a. Are responsible for the delivery of services to benefit the public and/or redistribute income and wealth;
- b. Mainly finance their activities, directly or indirectly, by means of taxes and/or transfers from other levels of governments, social contributions, debt or fees; and
- c. Do not have a primary objective to make profits.

There is a close relationship between the SNA and IPSAS. They are both accrual-based accounting standards and have similar measures of revenues, expenditures, assets, and liabilities, and similar accounting concepts of control, economic substance, recognition, and valuation. Compilation of macroeconomic statistics in accordance with the guidelines of the SNA is facilitated by the adoption of IPSAS by public sector entities.

30.175 The SNA and IPSAS have different objectives, as shown in Table 30.1. The objective of IPSAS is to provide useful information for accountability and decision-making on the finances of public sector entities, while the SNA provides information for monitoring and analyzing the performance of an economy. The SNA is an integrated system of accounts covering the total economy and its five institutional sectors, one of which is the general government sector. Government-controlled units that are market producers or that are non-resident are outside the boundary of the general government sector, but IPSAS do not distinguish between market and non-market producers, or between resident and non-resident units.

30.176 The difference in objectives causes some differences in the information presented and in how accounting concepts are implemented. The main differences between IPSAS and the SNA involve the reporting entity, consolidation, asset recognition, liability recognition, valuation, and the treatment of revaluations and other changes in volume.

30.177 Reporting entity: In IPSAS, the reporting entity is a government or other public sector organization, program or identifiable area of activity that prepares general purpose financial reports. In the SNA, the elementary entity for statistical reporting purposes is an institutional unit, which is an entity that is capable, in its own right, of owning assets, incurring liabilities, and engaging in economic activities in its own name. However, the data reported in the SNA focuses on groups of institutional units (sectors or subsectors).

30.178 Consolidation: In IPSAS, consolidation within the controlling entity is required. In the SNA, flows between units within the sector or subsector are generally not consolidated, but consolidated accounts may be compiled in supplementary presentations and analyses, as is the case for the general government sector. The consolidated general government sector comprises resident institutional units controlled by government and engaged in non-market production. In IPSAS all entities controlled by the reporting entity are consolidated regardless of their market/non-market producer and residency status.

30.179 Recognition of assets: IPSAS recognizes assets based on control, while the SNA recognizes assets based on economic ownership, where the economic owner is the institutional unit entitled to claim the benefits

associated with the use of the resource in the course of economic activity by virtue of accepting the associated risks. For example, the party treated as the owner of the asset in some public-private partnerships or service concession arrangements could be different under the two approaches.

30.180 *Recognition of liabilities:* In IPSAS, a liability is recognized whenever there exists an obligation of the entity to transfer resources as a result of past events and an estimate can be made of the amount of the obligation. However, in the integrated framework of the SNA, the need for symmetric recording means that a liability can only be recognized if there is a recognizable claim by a counterparty. This can affect the recording of provisions. For example, a provision for environmental restoration that is recognized as a liability in IPSAS might be disclosed in supplementary tables in the SNA but would not be recognized in the sequence of economic accounts.

30.181 *Valuation:* In IPSAS, assets are valued by applying either a historical cost model or a current value model. In the SNA, the methods for valuing assets try to approximate the current market prices or, in case (equivalent) market prices are not available, the current operational value or for some financial instruments the nominal value.

30.182 *Revaluations and other changes in volume of assets:* IPSAS include some changes in the value of assets caused by price changes and other changes in volume in the surplus or deficit (which is the balancing item of the Statement of Financial Performance) and include some others directly in the net assets/equity component of the Statement of Financial Position. In the SNA, revaluations and other changes in the volume of assets and liabilities are kept separate from transactions, so they do not affect earned income and/or disposable income.

**Table 30.1. Comparison of SNA and IPSAS**

<u>System of National Accounts</u>	<u>IPSAS</u>
<b><u>Objective</u></b>	
<u>Allow users of macro-economic statistics to monitor and analyze the performance of the economy.</u>	<u>Allow users of general purpose financial reports to evaluate the financial performance and financial position of public sector entities, and to hold management accountable and inform decision-making</u>
<b><u>Reporting Unit</u></b>	
<u>Institutional units and sectors: The statistical reporting unit is an institutional unit, defined as an entity that is capable, in its own right, of owning assets, incurring liabilities, and engaging in economic activities in its own name. However, the primary focus is on groups of institutional units (sectors or subsectors).</u>	<u>A reporting entity is a government or other public sector organization, program or identifiable area of activity that prepares general purpose financial reports. A reporting entity may comprise two or more separate entities that present general purpose financial reports as if they are a single entity; such a reporting entity is referred to as an economic entity or group reporting entity.</u>
<b><u>Scope</u></b>	
<u>Total economy and the resident units comprised by its five institutional sectors. The general government sector includes government units at all levels of government, social security funds, and non-market producers controlled by government units.</u>	<u>Public sector entities that meet the following criteria:</u> <u>(a) Are responsible for the delivery of services to benefit the public or redistribute income and wealth;</u> <u>(b) Mainly finance their activities, directly or indirectly, by taxes and/or transfers from other levels of government, social contributions, or fees; and</u> <u>(c) Do not have a primary objective of making profits.</u>
<b><u>Consolidation</u></b>	
<u>Flows between the units within a sector or subsector are generally not consolidated.</u>	<u>IPSAS requires presentation of consolidated financial statements for the controlling entity. In this case, the reporting unit is the economic entity, defined as the controlling entity and its controlled entities. Control is the main criterion that determines consolidation. At the highest level of consolidation, the whole-of-government reporting entity may include government departments, subnational</u>
<u>Consolidated accounts are compiled for complementary or analytical presentations, including for the general government sector.</u>	

<u>System of National Accounts</u>	<u>IPSAS</u>
	<u>bodies such as state governments, government-owned enterprises, and non-resident entities.</u>
<u>Recognition of Assets</u>	
<u>Based on economic ownership. The economic owner of a non-financial asset or financial asset is the institutional unit entitled to claim the benefits associated with the use of the asset by virtue of accepting the associated risks.</u>	<u>Based on control. Control of the resource entails the ability to use the resource (or direct other parties in its use) so as to derive the benefit of its services or other economic benefits embodied in the resource.</u>
<u>Recognition of Liabilities</u>	
<u>To maintain symmetric recording in the integrated framework of economic accounts, liabilities are only recognized when there is a recognizable corresponding claim of a counterparty. For example, provisions for environmental restoration are recognized but not in the main framework of economic accounts.</u>	<u>A liability is recognized whenever an obligation to transfer resources exists as a result of past events and the obligation can be measured.</u>

**Table 30.1. continued**

<u>System of National Accounts</u>	<u>IPSAS</u>
<u>Valuation</u>	
<u>Current market prices are used to value flows and stocks. Production cost, the market price of a similar item, the written-down current replacement cost or present value of future benefits may be used as alternative valuation methods if a market price is unavailable.</u>	<u>On initial recognition, IPSAS requires measurement at transaction price, or deemed cost where appropriate. On subsequent measurement, historical cost, current operational value, cost of fulfilment, or fair value may be used.</u>
<u>Revaluations and Other Volume Changes</u>	
<u>Holding gains or losses are reported in the revaluation account, and changes in volume are reported and in the other changes in volume account.</u>	<u>Some gains or losses due to revaluations or changes in volume of assets and liabilities are recognized in the Statement of Financial Performance and some are recognized in the Statement of Financial Position.</u>

## Chapter 31: Non-profit institutions

### (OLD Chapter 23: Non-profit institutions)

Note: The changes introduced in this chapter are to maintain consistency with the 2018 *Handbook on Satellite Account on Non-profit and Related Institutions and Volunteer Work*. The 2018 handbook updated the recommendations of the 2003 *Handbook on Nonprofit Institutions in the System of National Accounts* by extending the coverage of the satellite account beyond NPIs to include related institutions in the social economy such as cooperatives, mutual societies and social enterprises with a primarily social or public benefit purpose.

#### A. Introduction

##### 1. Non-profit institutions in the SNA

- 31.1 Non-profit institutions (NPIs) play a somewhat unusual role in the SNA. Like corporations, some NPIs produce goods and services for sale with the intention to cover costs – that is to say, as market production. In common with other market producers, they cannot undertake final consumption. Like government units, some NPIs are non-market producers and make their output available free or at prices that are not economically significant to individual households or the community at large. Some of these non-market NPIs are controlled by government and included in the general government sector but those that are not are grouped in their own sector, the non-profit institutions serving households (NPISHs).
- 31.2 Most NPIs are separately identified institutional units. That is, they are capable in their own right of owning assets, incurring liabilities and engaging in economic activities and in transactions with other entities. It follows that a complete set of accounts for the unit, including a balance sheet of assets and liabilities, exists or could be constructed if required. In some countries, especially developing countries, an NPI may be an informal entity whose existence is recognized by society but does not have any legal status.
- 31.3 The distinguishing feature that identifies an NPI is that its status does not permit it to be a source of income, profit or other financial gain for the units that establish, control or finance it. An NPI may make a profit, it may be exempt from taxes, and it may have a charitable purpose, but none of these are determining characteristics. The only essential criterion for a unit to be treated as an NPI is that it may not be a source of income, profit or financial gain to its owners.
- 31.4 All NPIs produce goods and services, most often services, intended for consumption by households or by corporations. Some NPIs that produce services for corporations typically ~~charging~~ charge fees (sometimes described as subscriptions and membership dues) intended to cover costs. They are often set up as associations that provide services exclusively to members. The level of fees charged, the price of membership, typically satisfies the SNA criteria of economically significant prices. For this reason, these NPIs are allocated to the corporations sectors. An example of an NPI serving corporations is a trade association.
- 31.5 A non-market NPI may be controlled by government in that government may appoint its officers and determine the objectives of the institution. It is treated as an institutional unit separate from government because it has independent control of its budget (even if much or all of the funding comes from government) but it is allocated to the general government institutional sector. Such institutions provide individual and collective services. An example is a research institute controlled by government.
- 31.6 Other NPIs exist to provide goods and services to households either in return for a fee or free. When fees are charged, these may or may not cover a large proportion of the NPI's costs and therefore may or may not be deemed to be economically significant prices. When the fees charged are regarded as being economically significant, the NPIs concerned are treated as providing market goods and services and are allocated to the corporations sectors. Otherwise, the NPIs fall into the institutional sector of NPISHs.

31.7 Thus it is possible to categorize NPIs as follows:

- a. those providing services to corporations whose output is sold to the corporations concerned and treated as intermediate consumption;
- b. those that are controlled by government and provide individual or collective services on a non-market basis;
- c. those providing goods and services to households, divided between:
  - those that provide goods and services to individual households at economically significant prices;
  - those providing services to individual households free or at prices that are not economically significant;
  - those that provide collective services free or at prices that are not economically significant.

31.8 Those NPIs that fall under the first bullet point in category (c) are allocated to the corporations sectors and expenditure on their output is treated as final consumption expenditure by households. Those that fall under the second bullet point under (c) are allocated to the NPISH sector and their output is treated as actual final consumption of households delivered as social transfers in kind. Those that fall under the third bullet point under (c) are also allocated to the NPISH sector, but their output remains as actual final consumption of NPISHs.

31.9 There are thus ~~a number of~~ four sectors where NPIs appear in the SNA: in both the financial and non-financial corporations sectors, in the general government sector and in the separate sector of NPISHs. Compilation of subsectors of the first three sectors ~~are established to that~~ contain NPIs only is recommended to increase the visibility of market and government-controlled NPIs. Those NPIs in the corporations sectors may be further subdivided to show those that are foreign controlled, those that are publicly controlled, and those that are subject to national private control. The NPIs in the general government sector may be subdivided by level of government; central, state, and local government. NPISHs may be divided between those that are foreign controlled and those subject to national private control.

## 2. The accounting rules for NPIs in the SNA

31.10 The output of NPIs is valued in the same way as for all institutional units. If the unit is a non-market producer, output is valued at the sum of costs, including ~~consumption of fixed capital but excluding a return to capital depreciation and a return to capital~~. If the unit is a market producer, output is measured by sales adjusted for changes in inventories and any production for own capital formation. ~~For some NPIs that cover a large proportion but not all their costs from sales, Some of the latter NPIs may fall short of covering all their costs from adjusted sales, leaving~~ the unit with a negative operating surplus. This negative operating surplus ~~is~~ may be covered by donations (current transfers).

## 3. ~~A satellite account for NPIs~~ thematic account on NPIs and other social economy institutions

31.11 For some time, there has been growing interest in studying the contribution to the economy of institutions such as NPIs because they are seen to constitute ~~significant~~ presence of growing economic and policy ~~interest~~ relevance. Such institutions are variously referred to as “non-profit”, “voluntary”, “civil society” or “non-governmental” organizations and collectively as the “third”, “social economy”, “voluntary”, “non-profit” or “independent” sector, attract interest because their operating characteristics are somewhat different from those of other units in the corporations and government sectors. Specifically:

- a. They are not permitted to distribute profits (if an NPI) or are significantly restricted in their ability

to distribute profits;

- b. They may produce public goods as well as private goods;
- c. They may receive as much or more from current transfers than they receive from selling their output;
- d. They may depend on volunteer labour as well as paid labour;
- e. Because they typically cannot pay dividends, they cannot attract equity capital in competition with corporations;
- f. They may be eligible for special tax advantages ~~in many countries;~~
- g. They typically have special legal provisions covering the governance, reporting requirements, political participation and so on;
- h. Although they provide public goods and services, they do not have the same powers or restrictions as government in deciding what these goods and services should be and how they should be allocated.

31.12 ~~Arising out of this interest, a satellite account for NPIs has been developed as described in the *Handbook on Non-Profit Institutions in the System of National Accounts* (United Nations, 2003). Sections B and C describe the essential features of this satellite account. Section D discusses some other aspects of NPIs that it may be desirable to explore in addition to the satellite account. The integrated framework of economic accounts provides limited visibility into the importance of NPIs in the economy because a large number of these NPIs are likely to be subsumed within the aggregates for corporations and government. To bring visibility to NPIs, guidelines for a thematic account on NPIs and related institutions have been developed, as described in the *Handbook on National Accounting: Satellite Account on Non-Profit and Related Institutions and Volunteer Work* (United Nations, 2018). This thematic account also contains data on related institutions with a social or public benefit purpose that are not NPIs and on volunteering. Sections B and C describe the essential features of this thematic account.~~

## **B. The units included in the thematic account on non-profit and related social economy institutions**

31.13 ~~The starting point for developing a thematic account is to identify the units of interest. As will be seen, the units chosen coincide largely (but not quite entirely) with the units described as NPIs in the SNA. One way of approaching a satellite account, therefore, would be to consider compiling One possible approach would be to compile the complete sequence of accounts for an NPI sector made up of the NPI subsectors in the non-financial corporations sector, the financial corporations sector and the general government sector, and the whole of the NPISH sector. However, because many of those interested in accounts for NPIs only do not come from an SNA background, the handbook starts by identifying characteristics of the units of interest. many of the analytical questions related to NPIs require a broader view of institutions that have a social or public focus that includes some units that are not NPIs. Expanding the boundary of the concept covered by the thematic account to include these units therefore enhances the usefulness of the thematic account.~~

### **1. ~~Determining characteristics of units for the satellite account~~Characteristics of the units included in the thematic account on non-profit and related social economy institutions**

31.14 Various alternatives have been put forward for the concept around which a ~~satellite~~thematic account for non-profit institutions could be formulated. The first of these is the concept of the “social economy” which depicts non-governmental institutions with a social or collective purpose. ~~Typically,~~ Mutual societies, cooperatives and associations would be included.

31.15 The second concept is that of “public benefit” organizations. This covers a narrower range of institutions that

serve a broad public purpose and excludes institutions that serve only their own members

31.16 ~~In between these two is the concept of the non-profit sector on the lines initially pioneered by the Johns Hopkins Comparative Non Profit Sector Project. In this project a definition of the non-profit units was elaborated along structural-operational lines. The “third sector” or “social economy sector” covered by the thematic account discussed in the Handbook on National Accounting: Satellite Account on Non-Profit and Related Institutions and Volunteer Work encompasses non-governmental institutions that have social or public primary purpose. In the case of the related institutions, a restriction limiting the share of a unit’s profit that can be distributed to its members or owners to no more than half is generally treated as consistent with having a social or public primary purpose. The requirements for inclusion in the thematic account as an NPI or related type of institution are~~ the following:

- a. ~~The~~ organizations should exist as identifiable institutions;
- b. They should be institutionally separate from government;
- c. They ~~do not~~are not permitted to distribute profits ~~(if an NPI), or are significantly restricted in their ability to distribute profits;~~
- d. They are self-governing ~~—~~ that is to say they are not subject to control by other units;
- e. Membership ~~of in~~ the unit is neither obligatory nor automatic but involves some degree of voluntary participation.

31.17 The main exclusions from the set of NPIs recognized in the SNA are those NPIs allocated to the general government sector because, although they are institutionally separate from government, they are controlled by government units. There are a small number of informal, usually temporary, NPIs that may be excluded also. These are discussed in section D.

## 2. Examples of non-profit units included

31.18 The following are illustrative examples of the kinds of entities that are likely to be found within the “non-profit sector” for the purposes of the thematic account on NPIs and related institutions. ~~satellite account~~.

- a. *Non-profit service providers*, such as hospitals, higher education institutions, day-care centres, schools, social service providers and environmental groups;
- b. *Non-governmental organizations* promoting economic development or poverty reduction in less developed areas;
- c. *Arts and culture organizations*, including museums, performing arts centres, orchestras, ensembles and historical or literary societies;
- d. *Sports clubs* involved in amateur sport, training, physical fitness and competitions;
- e. *Advocacy groups* that work to promote civil and other rights, or advocate the social and political interests of general or special constituencies;
- f. *Foundations*, that is, entities that have at their disposal assets or an endowment and, using the income generated by those assets, either make grants to other organizations or carry out their own projects and programs;
- g. *Community-based or grass-roots associations* that are member-based and offer services to or advocate for members of a particular neighbourhood, community or village;
- h. *Political parties* that support the placing of particular candidates into political office;
- i. *Social clubs*, including touring clubs and country clubs, that provide services and recreational opportunities to individual members and communities;
- j. *Unions, business and professional associations* that promote and safeguard labour, business or professional interests;

- k. *Religious congregations*, such as parishes, synagogues, mosques, temples and shrines, which promote religious beliefs and administer religious services and rituals. However, an official state church incorporated into the state administration, particularly one supported by obligatory taxes, would not meet the “institutionally separate from government” criterion and thus would be excluded from the set of NPIs in the -satellite thematic account. It should be noted that religious congregations are different from religiously affiliated service agencies in such fields as health, education and social services. ~~Similarly,~~ service organizations related to a state church might still be considered to be within the non-profit sector, as long as they are separate institutional units and meet all the definitional criteria.

Both market and non-market units should be included in each of these categories, so long as the institution concerned is an NPI (and not just ~~an~~ NPISH~~s~~).

~~31.19~~

### 3. Borderline cases

~~31.20~~ 31.19 Certain other types of organizations are likely to occupy a grey area between the non-profit sector and either the corporations or general government sectors. Some of those entities will properly belong within the non-profit sector but most of these entities are part of the social economy covered in the related institutions segment of the thematic account on NPIs and related institutions. for purposes of the NPI satellite account, while others will not. The following guidelines may be helpful for making those decisions. (Obviously, these guidelines will have to be applied to types of organizations and not on an organization-by-organization basis, but the decision rules can still be instructive.) ~~The guidelines given here are those of the handbook, slightly modified in the light of experience with implementing the accounts. It is proposed that the modifications included here will be incorporated into the next edition of the handbook. A key criterion for a unit to be includable in the thematic account is being prohibited or significantly restricted from distributing its profit. The main types of social economy institutions that can distribute a restricted share of their profit (usually defined as no more than half) are cooperatives, mutual societies, and social enterprises.~~

~~31.21~~ 31.20 *Cooperatives* are organizations formed freely by individuals to pursue the economic interests of their members. The basic principles of cooperatives include:

- a. democratic control, that is, one person, one vote;
- b. shared identity, that is members are both owners and customers; and
- c. orientation to provide services to members “at cost”.

As with other institutional units, if the articles of association of a cooperative prevent it from distributing its profit, then it will be treated as an NPI; if it can distribute its profit to its members, it is not an NPI ~~(in either the SNA or the satellite account).~~ However, if it is significantly restricted in its ability to distribute its profit to its members, it should be included in the thematic account as a related institution with a social purpose.

~~31.22~~ 31.21 *Mutual societies* include such organizations as mutual savings banks, savings and loan associations, mutual insurance companies, sickness funds, and burial funds. Mutual societies, like cooperatives, are organized by individuals seeking to improve their economic situation through collective activity. They differ from cooperatives, however, in that they are mechanisms for sharing risk, either personal or property, through periodic contributions to a common fund. Normally the depositors in mutual societies formally control their operations.

31.22 Because mutual societies operate in the commercial sphere, they fall in the financial corporations sector. Only if their articles of association prevent them from distributing profits to their memberowners are they treated as NPIs in the SNA (but still within the financial corporations sector) and included within the NPI sector for part of the satellite thematic account. However, they are included in the thematic account as related

institution with a social or public benefit purpose if they are permitted to distribute a restricted portion of their profit to their members.

31.23—

31.24 31.23 Self-help groups are similar to both cooperatives and mutual societies in that individuals join to accomplish goals of mutual support that would be unattainable on an individual level. They differ from both, however, in that they are not principally engaged in commercial activities. As a general rule, self-help groups should be treated as membership organizations and included within the non-profit sector.

31.25 31.24 Social enterprises (or social ventures) are enterprises organized for ~~the purposes~~ of employing and training disadvantaged individuals (handicapped, long-term unemployed, etc.) who would otherwise not find employment, supplying products of special social value, or serving disadvantaged persons in other ways. The enterprise is considered an NPI unless it generates and distributes its surplus to owners or stockholders. However, social enterprises that distribute a restricted portion of their surplus to owners or stockholders are included in the thematic account as related institutions with a public benefit purpose.

31.26 31.25 Quasi-non-governmental organizations, which are found in many European countries and elsewhere, are designed to function at arm's length from government departments, thus avoiding direct political control. To the extent that they are truly self-governing entities, they are appropriately considered part of the non-profit sector, even if they exercise the limited authority delegated to them by government agencies.

31.27 31.26 Universities, like other institutions, can be either NPIs, public institutions or for-profit corporations. Differentiating NPIs from public institutions is especially difficult since both may receive significant amounts of government support, either directly or indirectly, and since even public institutions may have a significant degree of autonomy. The key, therefore, is whether the institution is clearly self-governing and not part of the government's administrative system. Educational institutions that are NPIs will have their own self-perpetuating boards that can determine all facets of organizational operations, without approval by government officials, and that can cease their operations without the approval of government authorities. Public educational institutions will have boards selected in significant part by government officials or agencies and lack the power to cease operations without an act of the government.

31.28 31.27 Hospitals, like educational institutions, can also be either NPIs, public institutions or for-profit corporations. The same rules that apply to educational institutions also apply to hospitals.

31.29 31.28 Indigenous or territorial groups, such as "band councils" in Canada (a form of First Nation government) and peasant or native communities in Peru, are organized around either cultural or ethnic groupings or a particular geographic area, mainly with the purpose of improving the welfare of their members. The difficulty arises when such groups essentially operate as local governments, often making and enforcing their own laws. When that is the case, the groups do not meet the "institutionally separate from government" criterion and fall outside the boundaries of the thematic account. ~~NPI-satellite account.~~

#### 4. Classification of NPIs

31.29 NPIs can be classified according to the activity they undertake or their envisaged purpose ~~for which they are envisaged~~. In terms of activity, the normal classification to be used is ISIC. Because the detail available in ISIC, Rev. 3 for many of the social services covered by NPI was not sufficient, an elaboration of the basic ISIC codes was developed for use in conjunction with the NPI satellite account. The updated version of this classification is known as the International Classification of Non-Profit and Third Sector Organizations (ICNP/TSO). Similarly, some elaboration of the classification of NPIs by purpose (COPNI) was developed. In ISIC, Rev. 4, however, an alternative aggregation for data reporting for non-profit institutions is given in part four, section D. The twelve main headings-sections of the ICNP/TSO of interest are shown in table 23.1.

Table 23.1: ICNP/TSO ~~groups~~Sections

ICNP/TSO Section
------------------

Section A: Culture, communication and recreation activities

Section B: Education services

Section C: Human health services

Section D: Social Services

Section E: Environmental protection and animal welfare activities

Section F: Community and economic development, and housing activities

Section G: Civic, advocacy, political and international activities

Section H: Philanthropic intermediaries and voluntarism promotion

Section I: Religious congregations and associations

Section J: Business, professional and labour organizations

Section K: Professional, scientific, accounting and administrative services

Section L: Other activities

31.30

## C. Accounts included for non-profit institutions in a thematic satellite account on NPIs and related social economy institutions

31.31 The first set of accounts ~~prepared~~included in the ~~thematic satellite~~thematic account on NPIs and related institutions corresponds exactly to those in the SNA sequence of accounts. Indeed, this can be seen as a simple aggregation across the subsectors for the NPIs in the corporations sectors plus NPISHs. NPIs in the general government sector are excluded from the ~~satellite-thematic~~thematic account, as noted above.

31.32 The second version of the accounts ~~is to consider~~s those NPIs that provide services at economically significant prices but where the sales of their output bring in revenue that is significant but less than the whole of their costs. Two possible scenarios exist. The first is that the organization enterprise undertakes different types of activities, some on a market basis and some on a non-market basis, but with the market basis activities predominating. Although the two types of activity cannot be allocated to separate institutional units, separate establishments for each can be distinguished. In principle, the production account of the establishments undertaking market activities should measure output by sales adjusted for changes in inventories and own-account fixed capital formation ~~be compiled as normal~~ but the production account for the non-market establishments should be based on the sum of costs. The value of this non-market output should be treated as distributed to households as social transfers in kind and added to household actual final consumption.

31.33 The second possibility is that only one sort of activity is undertaken but the sales cover a large part of the costs, with the balance being made up of donations. The donations are treated in the SNA as current transfers (any donations designated for capital purposes being treated as capital transfers). The ~~thematic satellite~~thematic account treats these donations as analogous to subsidies and so measures the value of the output as the total sum of costs. In this case, the excess of output measured ~~in this way~~by costs over the proceeds from sales is treated as non-market output, social transfers in kind and part of actual consumption of households.

31.34 The third variant on the accounts builds on the second version of the accounts by also including an estimate of the value of volunteer labour used in the NPIs. Volunteer labour constitutes a significant input to many NPIs. If a value is placed on this, it may exceed the value of monetary donations to some NPIs. In the ~~satellite-thematic~~thematic account, it is recommended that the value of voluntary labour is estimated on the basis of

the remuneration rates of employees undertaking similar work and not at the opportunity cost of the volunteers. ~~Work is proceeding on the measurement of volunteer labour in the context of a satellite account. A draft The Manual on the Measurement of Volunteer Work (International Labour Organization, 2011 forthcoming) was presented to the ICLS in December 2008 provides guidelines on measuring volunteer work.~~

~~31.35~~31.34 The cost of the volunteer labour is treated as both part of compensation of employees and as a transfer back from these employees to the NPI where they work. The value of the output of the NPI, and the amount treated as social transfers in kind, is increased over the amount in the second version of the accounts by the estimated value of the volunteer labour.

~~31.36~~31.35 The ~~satellite thematic~~ account includes other tables apart from the sequence of accounts. One of these ~~is to show shows~~ details of revenue received with a breakdown by sector of origin and type of transaction. In particular, it is recommended to distinguish revenue coming from government split between sales and grants, and ~~revenue that~~ coming from the rest of the domestic economy split between private sales and current transfers (donations). Where possible both sales and transfers should be separated into those coming from the domestic economy and from the rest of the world.

31.36 Another table includes information in physical units such as the number of employees, number of volunteers, number of entities and number of members of the organization. In addition, some information is given on the financial account and the assets held by the NPI.

~~31.37~~

~~31.38~~31.37 ~~Fully annotated descriptions~~ Formats of the tables are included in Annex I of the Handbook on the Satellite Account on Nonprofit and Related Institutions and Volunteer Work.

## D. Other SNA considerations concerning NPIs

### 1. NPISHs and government

~~31.39~~31.38 In some countries, NPISHs take responsibility for the provision of specific services to households that the government does not see as part of its role to provide. In others, especially developing countries, NPISHs may provide services government would like to provide but simply does not have sufficient resources to do so. This becomes very clear following a natural disaster when NPISHs may be very active in relief work.

~~31.40~~31.39 Whether the unit undertaking the work is resident or not will depend on the normal rules concerning residence. Quick response actions that do not lead to long-term involvement in the country being assisted will be regarded as non-resident, with the production being recorded in the home countries of the units giving assistance and the assistance itself being shown as imports of goods and services funded by transfers. If the assistance extends beyond one year, the unit providing the assistance will be regarded as resident and a unit in the NPISH sector of the country receiving the assistance. In circumstances where international relief is important, it may be helpful to identify NPISHs subject to foreign control separately from other NPISHs and to identify donations from abroad for all NPISHs.

### 2. Informal and temporary NPISHs

~~31.41~~31.40 Quite frequently, a number of households may get together to pool resources of knowledge and volunteer labour to serve their local community. This could include teaching in informal schools, offering medical assistance or the construction of roads, a well, a school building, etc. When only services are provided on the basis of volunteer labour, no value for the output of the activity is recorded in the SNA.

~~31.42~~31.41 When physical structures result, the activity is included in the production boundary. The value of the output is estimated by comparison with similar products elsewhere in the economy or, when it has to be estimated at the sum of costs, an estimate is made for the implicit value of the labour input. This labour input is treated as gross mixed income accruing to households who then are assumed to “purchase” the product. In fact, they may then transfer the product to another unit, often government, for maintenance. However, the

recommendation in the SNA, as described in ~~paragraph 5.242-4.168-5.234~~, is that such organizations should be treated as informal partnerships rather than as NPISHs.

~~31.43~~31.42 If a group of households cooperates to produce goods for sale, even if the objective is still to be able to pay for work on a communal asset, this is not treated as a non-profit institution but as an unincorporated enterprise in the household sector.

~~31.44~~31.43 Many small groups of individuals or households may exist as a practical means of allocating shared costs. These may be as simple as a “coffee club” at the workplace or may be a more formal arrangement whereby the costs of common services provided to all tenants in a block of flats are shared equitably. Such groups are practical rather than economic. They are not treated as NPIs and their activities are not recorded in the SNA. Such costs as they incur should be recorded as paid by the units to which the costs are eventually allocated.

~~31.45~~31.44 In the case of microfinance, the unit providing the service is most likely to be either a corporation or an unincorporated enterprise. Even though the owner of the enterprise may not keep the profits but uses them to generate new loans, this does not automatically make the unit an NPI. The definition of an NPI is not that the owners choose not to withdraw profits but that they are not legally entitled to do so.

~~31.46~~—

~~31.47~~31.45 In practice it may be difficult to compile information on informal NPISHs unless the results are sufficiently important to come to general attention.

### 3. The output of NPISHs

~~31.48~~31.46 NPISHs produce goods and services, but typically services, that are provided to individual households free or at prices that are not economically significant. However, it is possible conceptually for an NPISH to provide collective services. An example may be a well-financed institution that engages in research and development but makes its results freely available. Such an institution is engaged in non-market production but, because it is not controlled by government, it falls in the NPISH sector. The value of its output is treated as final consumption expenditure and actual final consumption by the NPISH itself.

~~31.49~~31.47 The services provided by non-profit institutions serving households are not only very similar to those provided by government. They present much the same difficulties of measuring their output and of selecting suitable price indices for deflating output to volume terms.

## Chapter 32: Households (revised title and revised content)

(OLD Chapter 24: The households sector)

### A. Introduction

- 32.1 The economy functions because people want goods and services and are prepared to work to obtain them. At the most basic level there is subsistence activity where people work to grow food to eat. Any sort of development gives opportunities to earn money by working for others and using it to buy goods and services different from those one's labour has created.
- 32.2 In addition society recognizes that some individuals cannot participate in the economy in this way and so makes transfers available to the young, the old and the sick, for example. Often these transfers are undertaken by government which redistributes income on behalf of the community at large. In addition, transfers may be made by non-profit institutions or by extended family members, or others, based on traditional and cultural norms. Some individuals do not spend all their income but use some to acquire wealth.
- 32.3 Lastly there is income arising from the ownership of wealth. At its simplest, wealth is due to the accumulation of income earned in earlier periods (possibly generations earlier). Wealth gives rise to income because others wish to make use of it and pay to do so. In the SNA such payments are called property income. Like income, wealth may be transferred from one owner to another.
- 32.4 The SNA gives a clear and full accounting of all income accruing to households in the period itemized by type of income. It also accounts clearly for how this income is spent on goods and services, transferred to others or used to ~~acquire-accumulate more~~ wealth. However, while the sequence of economic accounts ensures that the accounts of all households are balanced, it does not show how this balance is achieved for subsets of households.
- 32.5 This chapter is about how to use information from the SNA sequence of economic accounts on the households sector in conjunction with other data sources to investigate the behaviour of households in greater detail. The focus here is on how income is used, how the patterns of income and use vary across types of households – also referred to as subsectors – and about the links between income and wealth at a detailed level. There are many different types of households that can be formed including those grouped by income decile, those undertaking unincorporated production activities and those whose members have specific characteristics (e.g. in terms of number or age of individuals).
- 32.6 ~~A Such a~~ focus on types of households is of both analytical and policy interest. It is a quite different view of economic behaviour from the predominant view of the SNA which is how income is generated. In the most structured form, accounts for the distribution of income, consumption and wealth across types of households, i.e., household distributional accounts, provide a rich and integrated dataset for the analysis of the household sector.
- 32.432.7 ~~In addition, as introduced in Chapter 2 and elaborated in Chapters 34 and 35, there is a wide range of data about the well-being and sustainability of households that can be organized using accounting approaches that is outside the scope of the sequence of economic accounts. Relevant topics include unpaid household service work, health care activity, education and training activity and human capital. These topics are not discussed in this chapter.~~
- 32.532.8 The difficulty in disaggregating the households sector arises for a number of reasons that are listed here and discussed further in Section B.4.
- The first is that income is earned by individuals but consumption is undertaken by households.
  - The second is that it is difficult to find a basis for subsectoring households such that the households in each subsector behave in a similar fashion to one another. Even if their income patterns are broadly similar, their expenditure patterns may differ according to the number and age of the members of the households. Grouping by the latter may give no similarity in the level of income.
  - The third reason concerns the source of data on household income and expenditure. Typically, information on corporations comes from establishment surveys and information on government comes from administrative sources. These sources are fairly comprehensive and are in large part the only source, or at least the primary source, for the data to feed into the SNA. Data for households

~~commonly~~often comes from household income and expenditure surveys ~~but these surveys which~~ are based on smaller samples, may be less frequent than establishment surveys and the data from them may be difficult to reconcile with the totals for income and expenditure that emerge from the accounting constraints in the SNA. ~~However, administrative data, for example those from taxation systems, may be available in some countries to provide higher levels of granularity and thus supporting improved disaggregation of data by type of household.~~

32.6 —

32.7 — Structure of the chapter

32.8 —

32.9 The households sector may be viewed in a number of different ways depending on whether the interest is primarily on what sort of production households undertake, what sort of income they earn or what patterns of consumption are portrayed. Given these different perspectives, it is not easy to come up with a single definitive set of subsectors for households. The conceptual and practical reasons for the difficulties are reviewed in section B. A review of possible subsectors is given in section C. The next ~~three~~ four sections (D, E, ~~and F and G~~) in turn look at households as producers, households as consumers and household income ~~and~~. ~~The last section, section G looks at household wealth and associated income flows. The last section, section H, discusses accounting for the distribution of household income, consumption and wealth.~~

## B. Household composition and ~~sectoring~~measurement

### 1. Definition of a household.

32.10 It is useful to begin by recalling the definition of ~~the~~ household given in paragraphs ~~[5.xxx]4.149 to 4.157. A household is defined as a group of persons who share the same living accommodation, who pool some, or all, of their income and wealth and who consume certain types of goods and services collectively, mainly housing and food.~~ In general, each member of a household should have some claim upon the collective resources of the household. At least some decisions affecting consumption or other economic activities must be taken for the household as a whole.

32.11 Households often coincide with families, but members of the same household do not necessarily have to belong to the same family so long as there is some sharing of resources and consumption. Households may be of any size and take a wide variety of different forms in different societies or cultures depending on tradition, religion, education, climate, geography, history and other socio-economic factors. The definition of a household that is adopted by survey statisticians familiar with the socio-economic conditions within a given country is likely to approximate closely to the concept of a household as defined in the SNA, although survey statisticians may add more precise, or operational, criteria within a particular country.

32.12 Domestic staff who live on the same premises as their employer do not form part of their employer's household even though they may be provided with accommodation and meals as remuneration in kind. Paid domestic employees have no claim upon the collective resources of their employers' households and the accommodation and food they consume are not included with their employers' consumption. They should therefore be treated as belonging to separate households from their employers.

32.13 Persons living permanently in an institution, or who may be expected to reside in an institution for a very long, or indefinite, period of time, ~~usually one year~~, are treated as belonging to a single institutional household when they have little or no autonomy of action or decision in economic matters. Some examples of persons belonging to institutional households are the following:

- a. Members of religious orders living in monasteries, convents or similar institutions;
- b. Long-term patients in hospitals, including ~~psychiatric facilities; mental hospitals;~~
- c. Prisoners serving long sentences;
- d. ~~Elderly Old~~ persons living permanently in ~~retirement care~~ homes.

- 32.14 On the other hand, persons who enter hospitals, clinics, convalescent homes, religious retreats, or similar institutions for short periods, who attend residential schools, colleges or universities, or who serve short prison sentences should be treated as members of the individual households to which they normally belong.

## 2. Residence

- 32.15 As described in Chapter 5, all members of the same household have the same residence as the household itself, even though they may cross borders to work or otherwise spend periods of time abroad. While aAll households are resident in the economy that is their centre of economic interest, but also of increasing interest is the phenomenon of a person abroad, often but not necessarily a family member, who remits significant amounts to the family in the domestic economy. (The same phenomenon also exists within a country, between urban and rural areas, for example.) The aspect of people moving abroad in response to better employment prospects may be seen as another facet of globalization and one that may have a significant impact on the distribution of income across households. It deserves to be monitored through the household distributional accounts (section II). The recording of remittances is discussed in detail in BPM Appendix 5.

## 3. Unincorporated enterprises

- 32.16 All households undertake final consumption and, to a greater or lesser extent, all undertake accumulation but a household does not necessarily undertake production. To the extent possible, the production activities within households are treated as being undertaken by quasi-corporations, included in one of the corporations sectors and separated from the rest of the household sector. However, as explained in paragraphs 5.xxx, a quasi-corporation can only be created when a full set of accounts, including balance sheet entries and information about withdrawals of income from the quasi-corporation, is available. Very frequently, and especially so in the case of a professional working alone, there may be complete information available on the production activities but it may not be possible to separate out other income flows, transfers and financial transactions relating to the production activity from those for the household in general. In this case as well as in ones where even the information on the production activity is incomplete, an unincorporated enterprise remains as part of the household.
- 32.17 Even when a quasi-corporation can be created and removed from the rest of the household accounts, the household may still include an unincorporated enterprise relating to other activity. For example, within a given household one person may be able to separate the production activity of repairing vehicles but another may not be able to separate the production activity of providing food for sale from the rest of the household's activities. Moreover, many households without any other production activities will contain unincorporated enterprises providing housing services from owner-occupied dwellings and from employing domestic staff.
- 32.18 Just as there may be production undertaken within the households sector, there may be people providing labour to these unincorporated enterprises. Members of the household who work in the unincorporated enterprise are called self-employed and their remuneration is termed mixed income rather than compensation remuneration of employees. Individuals who are not members of the household who are employed in an unincorporated enterprise are employees. It is possible but not always likely that the enterprise also pays for social security for these people. It is possible but even less likely that the household enterprise may offer other social insurance benefits to their employees.
- 32.19 There is further discussion about labour input employment within households in chapters 1649 and 3925.

## 4. Determining subsectors

- 32.20 As noted in the introduction, the difficulty in disaggregating the households sector arises for a number of reasons. The first is that income is earned by individuals but consumption is undertaken by households. While all households contain all individuals, it is very difficult to associate particular income recipients with particular household groups, i.e. subsectors. It is possible to have one table showing the types of income earned and the types of individuals receiving them. It is also possible to have a table of types of households and the pattern of

household consumption of each. Only in the highly stylized situation of one income earner only per household (and only one source of income) can the type of income be matched with the type of household and even then only if households are categorized according to the type of income. The problem could be compared to that of the supply and use tables but whereas it is possible to establish which industries make which products, there is no natural relationship between individuals as income recipients and the household to which they belong when households are grouped by any criterion other than main income source.

- 32.21 The problem of trying to link income flows from the SNA with ~~an analytically meaningful a-desirable~~ set of household characteristics ~~means that is one of the most difficult aspects of building a social accounting matrix.~~ Very often it is necessary to revert to modelling to reconcile income related to individuals to consumption related to households.
- 32.22 The second problem is related to the homogeneity of households. Various criteria may be used to disaggregate the sector (discussed in section C) but whatever criterion is used, it is difficult to assert that the behaviour of the sample ~~of households within a group~~ is typical of the whole. This is a difficulty not normally encountered in industrial classifications and surveys. For example, if a survey covers 50 per cent of firms in a given industry it is probably reasonable to suppose that the pattern of expenditure is typical of the whole. If an enterprise doubles its turnover, the level of intermediate consumption will probably approximately double but its composition may not alter significantly. Such assumptions are very suspect in the case of household groups. This is another area where it may be ~~necessary to use modelling to underpin analysis, difficult to use a social accounting matrix for analysis without having further recourse to modelling,~~ this time to determine how ~~individual households within a groups of households~~ react to different stimuli.
- 32.23 ~~The third reason concerns the sources of data on different types of households.~~ The information for the corporations sectors ~~generally~~ derives from ~~enterprise~~ surveys. The household aggregates of income and expenditure are ~~then~~ known from the accounting identities in the sequence of ~~economic~~ accounts. While it is true that information from household surveys may sometimes reveal errors in industry data or vice versa, it is more problematical to take information from household surveys on, say, expenditure patterns of one group of households and suppose all other members of the group behave in the same way. For this reason a household income and expenditure survey is often reported as a freestanding exercise and integration with the national accounts totals is not as frequently ~~undertaken as~~ part of compiling the full ~~set of national sequence of economic~~ accounts, as is the case with establishment surveys. In order to explore why this may be so, it is useful to look briefly at some of the problems experienced with household surveys.

## 5. Household surveys

- 32.24 Any attempt to disaggregate the households sector is likely to be dependent on a household income and expenditure survey. The conventions adopted by survey statisticians and those of national accountants are not always the same. A household expenditure survey for example may not include estimates of ~~owner-occupied housing services - imputed rental of owner-occupied dwellings or own account production for own final use.~~ It may measure income after tax and measure expenditure on a cash and not on an accrual basis. Various publications have been prepared to examine such differences and make recommendations on how to reconcile survey data with national accounts requirements. Particularly relevant is the *Final Report and Recommendations of the Expert Group on Household Income Statistics* (Canberra group, 2001) and *Household Income and Expenditure* (International Labour Organization, 2003). ~~In addition, relevant information concerning the use of micro data is available in the international guidelines for measuring the distribution of household wealth in micro statistics (OECD, 2013), and the framework for the integrated analysis of micro data on household income, consumption and wealth (OECD, 2013).~~
- 32.25 A major problem with household surveys is that it is very common for respondents to underestimate or underreport their income. This may be deliberate or may simply be a lack of understanding of what should be included, ~~a lack of access to detailed information~~ or ~~simple~~ forgetfulness.
- 32.26 Similarly some items of consumption are regularly underreported, most notably expenditure on alcohol and tobacco. On the other hand, consumption of some items is over-reported. For example, if a survey asks for expenditure on durables based on the recall of the respondent of what has been spent over the last two or three years, people often underestimate how long it is since purchases were made and will report more expenditure in

**Commented [ED1]:** Although not raised as a topic for updating in the 2025SNA, following feedback on the revised chapter, it is intended to review the text in this section (and other places in the chapter as relevant) to ensure that the content is current with respect to advances in the collection of households statistics

this period than has actually been the case. ~~This phenomenon does not only apply to very large items of expenditure; it is reported that household surveys have suggested that the purchase of toothbrushes, for example, is many times higher than in the sales reported by shops.~~

32.27 The problem of non-response is a concern in household surveys since it is quite likely that some of the households that refuse to respond have income and expenditure patterns that are different from respondents. For example people with incomes arising from illegal activities may be very reluctant to supply information and may choose not to participate in the survey. Similarly it is common for households at the very top and very bottom of the distribution to be omitted from the survey either by design or on the grounds of practicality.

32.28 Household surveys may be designed to investigate particular phenomena that are not necessarily the primary interest for national accounts. For example, they may be restricted to low income earners in urban areas. While this information is highly valuable and useful, it is not sufficient to produce aggregate figures for national accounts. Sometimes even if the coverage is more comprehensive, the sample size may not be such as to allow disaggregation along the lines desirable within the ~~sequence of economic national~~ accounts. It is important to realize that a desired pattern of subsectoring should be determined before the survey is undertaken to ensure the desired characteristics will be adequately represented in the survey sample.

32.2832.29 ~~Advances in the alignment of micro and macro data sources for the household sector have been made, particularly in the context of developing distributional accounts for households. For this purpose the reconciliation of data items across different household subsectors is a core part of the measurement approach. Section H provides an overview of relevant issues.~~

## C. Subsectoring households

### 1. The production perspective

32.2932.30 A first consideration is to investigate the possibility of subsectoring households according to their involvement in production. This may be done following the pattern shown in chapter ~~3925~~ to identify informal and other production activity undertaken by households.

32.3032.31 The first division is to separate institutional households and those households that do encompass an unincorporated enterprise from those that do not. Thereafter it is straightforward to identify those households whose only productive activity is connected with the owner occupation of houses or the employment of domestic staff. The households that are left may be further divided between those that employ staff to work in their unincorporated enterprises and those that do not. As described in the chapter on the informal sector, when proceeding along these lines it is sometimes desirable to identify the type of productive activity of an unincorporated enterprise, in particular identifying agricultural activity separately from other types of productive activity.

32.3132.32 Within the SNA, all household enterprises that can be treated as quasi-corporations because they have complete sets of accounts showing their ownership of assets (separately from those of the household to which they belong) and the withdrawal of income to their owners are classified in one of the corporations sectors. The number of household enterprises that can be treated as quasi- corporations, and thus removed from the households sector, varies considerably from country to country depending on the availability of accounting information and the resources available to identify such enterprises and treat them as quasi-corporations.

32.3232.33 Although it is possible to identify households that only have owner-occupied housing as their ~~unincorporated enterprise~~ productive activity, in many cases ~~other unincorporated enterprises~~ households will use their dwellings for a number of purposes. undertake owner occupation of their houses as well. While from a production point of view it is possible to separate the different types of production activities, for the institutional unit as a whole it is not possible to make this separation.

32.3332.34 In most countries, many households do not have unincorporated enterprises, so when subsectoring is done according to production undertaken by households, those without unincorporated enterprises are grouped together in a single, very large, subsector. The only common factor these households share is that they do not have an unincorporated enterprise. Thus while subsectoring households according to production is useful in some circumstances it has ~~its~~ limitations in terms of identifying the role of different types of households in the economy.

## 2. The consumption perspective

~~32.34~~32.35 It is widely observed that as household income rises so the pattern of consumption changes. The proportion of expenditure devoted to food and other necessities declines as more income is available and more expenditure is devoted to more luxury goods. Thus one approach to disaggregating households according to consumption patterns is in fact to disaggregate by level of income, assuming this captures the differences in consumption patterns. Studies showing consumption patterns according to income deciles are quite common and give interesting information about how patterns of consumption change as the overall level of income increases.

~~32.35~~32.36 The question arises of how household consumption patterns may relate to incomes of individuals. There is no obvious way to identify how recipients of income fall into one or other income deciles when ~~these~~ deciles are calculated on a household basis. Households with a high aggregate income may result from one very well-paid worker or from a number of middle income earners. Further, although the production account shows total compensation-remuneration of employees and it may be possible to compare this to the total number of employees, this gives no information about the distribution of income across the labour force in the enterprise. Not all income comes from compensation-remuneration of employees and the effect on total household consumption of other sources of income is equally uncertain.

~~32.37~~ Using the level of household income as a proxy for consumption patterns has some significant problems. One possible disaggregation of households where consumption patterns might be significantly different would be according to whether the household includes children and, where it does not, whether the household is relatively young (and may be setting up home for the first time) or relatively ~~old~~-elderly (where expenditure on consumer durables may be lower than for other groups). However, here again there is no easy way to link the source of the income with the type of consumption of the household in which the income recipient resides.

~~32.36~~32.38 While using the level of household income as a proxy for consumption patterns has some challenges, approaches for making suitable adjustments have been developed. At their simplest, national accounts measures often use a per capita approach or divide the income of the household by the number of household members. These simple adjustments, however, assume that there are no economies of scale from living in the same household. To reflect this effect, equivalence scales can be used to adjust household income to reflect the economies of scale achieved in consumption by households comprising more than one person. Section H provides a longer introduction to the use of equivalence scales.

## 3. The income perspective

~~32.37~~32.39 An ~~alternative -more promising-~~ approach to subsectoring ~~appears to come from considering~~ not the level of income and consumption but the type of income. ~~In this approach As proposed in chapter 4, the following scheme might be considered.~~ Households may be grouped into subsectors according to the nature of their largest source of income. For this purpose, the following types of household income need to be distinguished:

- Income accruing to the owners of household unincorporated enterprises with paid employees (employers' mixed income);
- Incomes accruing to the owners of household unincorporated enterprises without paid employees (own-account workers mixed income);
- Compensation-Remuneration of employees;
- Property and transfer incomes.

~~32.38~~32.40 Households are allocated to subsectors according to which of the four categories of income listed above is the largest for the household as a whole, even if it does not always account for more than half of total household income. When more than one income of a given category is received within the same household, for example, because more than one member of the household earns compensation-remuneration of employees or because more than one property or transfer income is received, the classification should be based on the total household income within each category. The four subsectors are described as follows:

- a. Employers;
- b. Own-account workers;
- c. Employees;
- d. Recipients of property and transfer incomes.

~~32.39~~32.41 The fourth subsector, households for which property and transfer incomes make up the largest source of income, constitutes a heterogeneous group and it is recommended that it should be divided into three further subsectors when possible. These subsectors are defined as follows:

- a. Recipients of property incomes;
- b. Recipients of pensions;
- c. Recipients of other transfer incomes.

#### 4. Using a reference person

~~32.40~~32.42 Other methods of subsectoring usually require a reference person to be identified for each household. The reference person is not necessarily the person that other members of the household regard as the “head of the household”, as the reference person should be decided on grounds of economic importance rather than age or seniority. The reference person should normally be the person with the largest income although the reference person could also be the person who makes the major decisions with regard to the consumption of the household.

~~32.41~~32.43 Once a reference person has been identified, it is possible to group households into subsectors on the basis of the reference person’s characteristics. For example, subsectors may be defined according to:

- a. Occupation of the reference person;
- b. Industry, if any, in which the reference person works;
- c. Educational attainment of the reference person;
- d. Qualifications or skills possessed by the reference person.

#### 5. The consequences of demographic change

~~32.42~~32.44 A growing policy interest in some countries is the effect of demographic change on household well-being and the response required by government. For example, in an ageing population, there may be less demand for educational services and more for health services.

~~32.43~~32.45 Another concern is whether pension provision is sufficient to ensure that individuals have an adequate level of income in retirement without looking to government for income support. A focus on such issues might suggest subsectoring households according to whether the reference person main income earner is (i) in work, (ii) of working age but not in work, or (iii) in retirement. Again, categorization according to the main income earner will give different results from categorizing income as a whole.

#### 6. Other considerations

~~32.44~~32.46 It is possible to consider subsectoring households on quite different grounds. Examples include the number of persons in the household, the region where the household is located, the qualifications or education level of the head of the household, the industry where the head of the household reference person works, whether the household owns property or other assets and so on.

### D. Households as producers

## 1. Households and the informal sector

[32.45](#)[32.47](#) In all countries, there are some production activities undertaken by households. Many of these may be described as informal and, as described in chapter [39](#)[25](#), measuring the extent of the informal sector and how this changes as the economy develops gives particular insight into the extension of the market economy beyond formal enterprises.

[32.46](#)[32.48](#) The difficulty of separating the productive activity of a household from the rest of the institutional unit has been discussed in a number of places in earlier chapters, particularly in chapter [45](#), and is referred to above in discussion about the subsectors for households. This section therefore discusses only some aspects of those productive activities that inevitably remain within the households sector.

## 2. Agriculture

[32.49](#) In some countries, subsistence agriculture, or indeed the results of any agricultural production which are used entirely by those responsible for the production, is a very significant part of household consumption and by extension of GDP. In countries where much of the staple food is grown for own consumption, and it is seasonal, it is necessary to consider whether some part of the increase in the value of the crop due to storage is part of production. There are details of how this may be done in the annex to chapter [67](#).

[32.47](#)[32.50](#) It should be recalled that the purchaser's price for agricultural products used for own consumption does not mean the price at the nearest local market which would include transportation costs. The market price is the price that somebody would pay for the crops where they are grown. This is frequently called the farm-gate price.

[32.48](#)[32.51](#) In principle, all fruit and vegetables grown for their own use by households with small allotments or large gardens should be included within the production boundary, even in developed countries. In practice it is unlikely to be worth the effort of making estimates unless the amounts involved are significantly large.

## 3. Housing

[32.49](#)[32.52](#) In almost all economies, a large number of households live in dwellings that they own, [thus requiring estimates of owner-occupied housing services](#). The size of the rental market may be very small and may be confined to some areas, for example urban areas, which makes it difficult to use [observed](#) market rentals as a means of estimating the services provided by all owner-occupied dwellings. In chapter [29](#)[18](#), it is explained that in principle the rent on [an capital-asset](#) can be calculated by applying a discount factor to the [value of the asset stock-of-capital](#) at the beginning of a period, so if the value of the house is known, a figure for the services provided can be estimated. However, this approach also is problematic in those circumstances where there are no data on the stock of capital or where there is uncertainty on the rate of return [to-be-estimated](#). For [simple](#)-rural dwellings, it may be necessary to calculate the cost of construction and estimate how long the building is usable without major renovation.

[32.50](#)[32.53](#) All dwellings require regular maintenance. The production account for [an-owner-occupied housing services dwelling](#) treats as intermediate consumption only the goods and services necessary to undertake the sort of repairs that are typically the responsibility of the landlord in the case of rented buildings. These may include payment to specialists in the building trade, for example plumbers or painters, and the cost of these specialists will include their [compensation-remuneration](#) of employees. However, when work is undertaken by the owner himself only the cost of the materials is included in intermediate consumption with no estimate made for the value of the owner's time spent on repairs. In consequence, there is no [compensation-remuneration](#) of employees appearing in the production account for owner-occupied [housing services dwellings](#). (This may be seen to be a pragmatic convention. If labour costs were to be imputed to the owner undertaking repairs, this would be recorded as income accruing to the household but the income from the [owner-occupied housing services rental on the house](#) would be reduced by an exactly offsetting amount.)

[32.51](#)[32.54](#) The whole of the [owner-occupied housing services imputed rental](#) less actual costs (including costs other than those relating to repairs, [such as other taxes on production](#)) incurred is treated as operating surplus of the owner. The accounts for the owner of the building show the whole of the value of the [owner-occupied housing services imputed rental](#) as output, any costs incurred as intermediate consumption and the difference as gross

operating surplus which is paid to the household in its capacity as the owner of the unincorporated enterprise. In the use of income account, the full value of the owner-occupied housing services of the rental is shown as part of household consumption of the imputed rental of owner-occupied dwellings.

~~32.52~~32.55 When major repairs are undertaken, these are treated as gross fixed capital formation and recorded following the treatments in Chapter 11. Note that gross fixed capital formation undertaken on own-account should include an estimate of the imputed value of labour input provided free, but the same conventions apply concerning the recording of compensation of employees following the treatment in 7.xxx. For more details on differentiating between regular maintenance and major repairs, see paragraphs 11.53 to 11.55.

~~32.53~~32.56 Some houses are owned by households but leased out by them. In this case the rental paid by the tenant is the value of the output of the rental service. The production account for the earning household shows intermediate consumption charged against this output to derive the operating surplus of the activity, which is treated as income to the owning household. In some cases, the whole of the intermediate consumption may be a service charge paid to a rental agency. It is conceivable that occasionally the service paid to the rental agency may exceed the rental income so that the rental activity produces a loss for the owning household. For example, if a house stands empty for a time, there may still be a fee payable to the rental agency. The earning household will often regard this as acceptable because one reason for owning a house to rent is because it is hoped a holding gain will be made on owning the house over a long period.

~~32.54~~32.57 By convention, all the value added arising from leasing dwellings by households is treated as operating surplus, not mixed income.

~~32.55~~32.58 Some houses will be owned as second homes either in the same economy or abroad. The same principles apply as in the case of owner-occupied housing services imputed rental of owner-occupied dwellings and rental services activities that come from renting out a house. If the house is in another country, it is treated as belonging to a notional resident unit in that country. The legal owner then has a financial claim on the notional resident unit. The notional resident unit therefore appears to be a direct investment enterprise wholly owned by a non-resident. However, the only asset of the unit is the value of the property and the whole of the operating surplus from renting out the house is treated as being withdrawn from the notional unit and remitted to the owner so there are no retained earnings remaining to be treated as reinvested earnings.

~~32.56~~32.59 To the extent that the house abroad is used by nationals of the economy where the legal owner is resident, the rentals should be treated as exports of services from the foreign country and imports of services to the domestic economy. However, the operating surplus of the notional unit is remitted to the owner and appears as a property income outflow from the foreign country and inflow to the domestic economy, offsetting the flows of rental services (at least in part).

~~32.57~~32.60 When a house is financed by a mortgage, in principle implicit financial services on loans and deposits FISIM charges relating to interest payments on the loan should be treated as part of the intermediate consumption of the production activity associated with renting the property (either for use by the owner or by a tenant). However, it may be difficult to identify implicit financial services on loans and deposits FISIM related only to interest on the mortgage and in some cases a loan using the property as collateral may not be used to secure the property for the purpose of having a dwelling available. In practice, if implicit financial services on loans and deposits FISIM are not treated as part of the intermediate consumption of the rental activity, the operating surplus from the rental activity, and GDP as well, will be higher than otherwise but the consumption expenditure of the household will be higher by the same amount.

#### 4. Domestic staff

~~32.58~~32.61 Services provided by paid domestic staff are valued at the remuneration cost of the compensation of employees paid to those staff but and including any income in kind such as free accommodation or free meals as well as any social insurance contributions that may be paid on behalf of the staff. By convention the production account for paid domestic services consists only of this compensation remuneration of employees. All of the products used in the performance of domestic services, such as cleaning materials and tools used, are treated as final consumption expenditure of the household.

~~32.59~~32.62 Individuals who provide paid domestic services must be members of another household. Payments to

children for performing tasks in the house are not treated as the provision of paid domestic services but simply as if the payment were a transfer within the household. On the other hand payments to a child for babysitting a neighbour's children should in principle be treated as domestic services but these may be too small and difficult to measure.

~~32.60~~32.63 In practice, some countries may include full-time domestic employees as members of the households, in which case a transfer within the households is recorded, even though transfers within an institutional unit are not normally recorded. This in turn means there is an element of double counting for the household concerned with a payment to the domestic staff and the expenditure by those staff both being included in the household's consumption expenditure.

## **5. Unpaid household service work**

~~32.61~~32.64 In chapter ~~34~~29 there is discussion of the possibility of extending the production boundary to record all forms of unpaid household service work and volunteering thus encompassing the production of ~~within the context of a satellite account to include~~ all domestic services, including those that are not performed in return for payment.

## **E. Households as consumers**

### **1. Consumption goods and services provided in kind**

~~32.62~~32.65 Chapter ~~109~~ describes the different concepts of consumption expenditure, actual consumption and the use of consumption goods and services. Within the SNA, only the first two are measured and the difference between them is accounted for by social transfers in kind provided by government and NPISHs to households. In principle it might be interesting to be able to distinguish social transfers in kind provided to children (for example most education), to the elderly (particularly health care) or perhaps on a regional basis. However, since there are considerable difficulties in working at this level of detail in the sequence of economic accounts, and so it is recommended probable that such extra detail is ~~could be provided only in thematic the context of a satellite accounts as described in Chapter 34 and 38 such as the health care activity account and the education and training activity account.~~

~~32.63~~32.66 In principle, transfers in kind between households should be recorded in the SNA. However, if there are no subsectors of the households sector, such transfers will not appear in the accounts when they occur between resident households. On the other hand transfers in kind between resident and non-resident households may be quite significant and should be captured through information on remittances in the balance of payments data. Practical considerations are described in International Transactions in Remittances: Guide for Compilers and Users (International Monetary Fund, 2008b).→

32.67 When there is a significant amount of consumption ~~represented by own accounts~~sourced from own-account production, income in kind, barter or transfers in kind it would be useful to itemize the distinction between consumption expenditure by households in kind from consumption purchased in the market place.

### **2. Expenditure by ~~tourists~~visitors**

32.68 Most data sources for household consumption from the supply side are not able to distinguish whether purchases are made by visitors from resident households or by non-resident households. Equally, the same sources will not reveal purchases made abroad by resident households. These two items are often of a sufficiently significant size that it is important that they be estimated both for the impact on the balance of payments and in order to ensure that the supply and use table can be adequately balanced. Further consideration of expenditure by tourists-visitors, in particular for tourists, can be undertaken following the general principles of thematic accounting described in Chapter 38.

~~is discussed in chapter 29 in the context of a tourism satellite account.~~

### **3. Consumption expenditure by type of product**

~~32.64~~<sup>32.69</sup> Most household surveys itemize consumption according to the purposes it is intended to serve: food, housing, etc. This type of breakdown is the one used in the Classification Of Individual Consumption by Purpose (COICOP). For inclusion in the supply and use table, and indeed for other analyses, it is useful to prepare a table showing the cross classification of consumption by purpose and by type of product. This is useful not only in terms of providing the information for the supply and use tables but also in examining the information used to compile consumer price indices, which in turn are used to deflate consumption expenditure. If the data permit, it may also be useful to look at the composition of consumption expenditure by type of household with a view to calculating consumer price indices for different groups of households, for example for the elderly or for those with young children.

## F. Household income

~~32.65~~<sup>32.70</sup> It is a well-established phenomenon in all countries that income is distributed unevenly and in a very skewed manner. Very many people have income significantly below the average or median income and very few people have extremely large incomes. A poverty line is sometimes quoted as half the median income but an income of twice the median does not imply great wealth; the wealthiest individuals in an economy may have incomes many times larger than the average or median income.

~~32.71~~ The reason that the sequence of economic accounts is important is that it gives a picture of how income is distributed and redistributed either compulsorily via taxes and benefits or voluntarily via transfers or because of ownership of financial or other assets (property income). In order to examine whether the process of distribution and redistribution of income significantly changes the overall distribution of income in the economy it is necessary to be able to show the flows between different groups of households. As noted in the introduction, it is difficult to allocate income and consumption across from one particular source to one household groups rather than another, distributional accounts for household income, consumption and wealth can be compiled as part of the sequence of economic accounts as described in Section H (below).

~~32.66~~<sup>32.72</sup> To complement the detailed information on different household groups presented in distributional accounts, a range of other ~~This is not straightforward and not a standard part of the SNA. However, it is straightforward to provide more information can be provided~~ to analysts on the type of household incomes building on the data from the other parts of than the total contained in the standard sequence of economic accounts. As far as value added is concerned, it may be possible to distinguish compensation-remuneration of employees paid by individual industries or perhaps according to level of education or by region. Mixed income can similarly be distinguished. Consumption of fixed capital~~Depreciation~~ should be separated between that due to owner-occupied dwellings and that relating to other assets of unincorporated enterprises.

~~32.67~~<sup>32.73</sup> The ~~standard sequence of economic~~ accounts contains information on transfers in the form of taxes paid and social insurance contributions and benefits split between pensions and other benefits. In some countries it is especially relevant to show personal remittances from abroad to demonstrate the impact on the domestic economy of those with strong ties to economies abroad. For countries with a large migrant population it may be similarly useful to identify the corresponding outflows and their destination.

~~32.68~~<sup>32.74</sup> Within property income it is useful to distinguish those flows that place resources at the disposal of the recipients from those where the receipts are already precommitted as saving, for example, pension entitlements, property income on life insurance and interest that derives from the increase in the value of bonds. It should be noted that it is particularly useful to identify the withdrawal of income from quasi-corporations if there are many household enterprises treated as quasi-corporations.

~~32.69~~<sup>32.75</sup> It may be useful to identify and show separately income in kind of all types, such as wages and salaries in kind and transfers in kind, and then derive a total excluding both these and the precommitted saving which might be called discretionary income.

## G. Household wealth and associated income flows

### 1. Household balance sheets

~~32.70~~<sup>32.76</sup> For many households, their main assets are their land, houses and accumulated pension entitlements.

Where they exist, claims on enterprises may also be significant. Investment in financial assets outside pension funds may also be important in some countries. However, set against the assets must be the liabilities of the households, including the loans involved in mortgages and other financial liabilities and, for example, credit card or other debt.

~~32.71~~32.77 For households including an unincorporated enterprise other than owner-occupied dwellings, there may be other fixed assets recorded on the balance sheet but these tend to be small relative to housing.

## 2. Family trusts

~~32.78~~ Trusts are arrangements whereby an economic agent (a trustee) holds property (but not economic ownership) as its nominal owner for the good of one or more beneficiaries. Their job is to hold, manage and administer the funds in the trust on behalf of the settlor (the creator of the trust). Their fiduciary duty as a trustee requires them to act in the best interest of the beneficiaries of the trust. The duties of a trustee are laid out upon the creation of the trust, and while they may differ depending on the situation, some tasks are common. The trustee oversees the distribution of the trust's funds to the beneficiaries. While the assets remain a part of the trust, the trustee is responsible for any investments that are made, ensuring any assets included in the trust, taking care of the administration, and overseeing the payment of taxes. ~~Family trusts are owned by households, though some trusts may be owned by a number of households collectively possibly including non-resident households. Trusts may be set up to protect wealth until a beneficiary comes of age or meets another criterion, they may be set up to preserve family estates and so on. The SNA recommends that trusts should be treated as quasi-corporations and included in the financial corporations sector as captive financial institutions. However the trusts must have liabilities to the beneficiaries sufficient to reduce their net worth to zero. In compiling the balance sheet for the households sector, the value of the assets corresponding to the liabilities due to resident households must be included.~~

~~32.72~~32.79 Looking more specifically at trusts set up by households, the trustee is not the economic owner of the assets. The trustee may be the legal owner of the assets, but the accumulated assets in the trust constitute a separate fund and are not part of the trustee's own assets, indicating that economic ownership is different from nominal/legal ownership. Where family trusts are important and when household wealth is the subject of interest, it may be useful to introduce a supplementary heading under other equity owned by households to show the value of trusts separately from the equity of other quasi- corporations such as partnerships. ~~There are a range of considerations in determining the appropriate treatment of trusts, including, for example the potential for trustees and the beneficiaries to be resident in different economies. The relevant treatments are described at length in Chapter 5, 5.103-111.~~

## 3. Pension considerations

~~32.73~~32.80 There is a question about whether the rundown of wealth post retirement should be recorded as income or as dis- saving.

~~32.74~~32.81 By treating pension schemes as social insurance schemes, pension benefits are shown as current transfers, and thus income, rather than as a run-down of saving. If a pension scheme is not treated in this way, though, there is still income accruing to the pension beneficiary in the form of the property income payable on the pension entitlements. For a defined benefit scheme, this property income represents the unwinding of the discount factor on future entitlements. The decrease in the entitlements is equal to the difference between the benefits payable and this property income, similar to the position for an annuity explained at the end of part 1 of chapter 17.

~~32.75~~32.82 ~~To the extent that the value of the pension as a form of wealth is based on the net present value of future income flows, pension receipts can be partitioned into the rundown of savings and income accruing.~~ In cases where there are no pension entitlements, a household with a significant level of financial assets is still likely to receive significant property income, though the mix of property income and holding gains and losses will depend on the investment strategy of the household concerned.

~~32.76~~32.83 For a household where one or more of the members is building a pension, significant income will accrue each year but this is not accessible to the household to spend. It must be accumulated to fund future pension

entitlements and thus shows as an increase in wealth.

32.7732.84 It is possible to construct an asset account for pension entitlements showing the ~~start-of-year~~-level of entitlements at the beginning of the year, increments due to contributions made-work done in the year, increases due to the fact that retirement has become a year nearer (the unwinding of a discount factor) and other changes such as an allowance for inflation, ~~less~~-decreases due to pension payments or other changes that reduce entitlements.

#### 4. Consumer durables

32.85 Within the SNA, consumer durables are not treated as a form of wealth but as a form of expenditure. However, there may be considerable interest in having a memorandum item in the balance sheets to show the worth of consumer durables. As noted in Section H (below) this memorandum item would also be relevant in the compilation of distributional accounts for households. The acquisition of durables may well be cyclical and there is interest in compiling a satellite-accounts that would replace the purchase of consumer durables as current expenditure by figures for the flow of services provided from the same items treated as fixed capital. The dual use of consumer durables as part of consumption activity of households and as inputs to production activity by unincorporated enterprises should be accounted for by partitioning the use of the durables. The measurement of is-consumer durables is discussed further in chapter 11.29.

#### 5. The distribution of wealth

32.7832.86 Increasing interest is being shown in conducting surveys of household wealth along lines similar to surveys of household income and expenditure. Again the interest is to look at a disaggregation of the households sector to discover the composition of household wealth and its relation to household income.

32.7932.87 In general the distribution of wealth is even more strongly skewed than income. A family where the main earners are in mid career may have a comfortable level of income and occupy their own house but still have a considerable mortgage and may not yet have built up significant pension reserves. These topics are considered further in Section H (below).

### H. Distributional accounts for household income, consumption and wealth

#### 1. Introduction

32.88 Aggregates and average growth rates for the accounting entries for each institutional sector only provide a partial story of the operation of the economy, in particular they may conceal large discrepancies between different types of households. Recognizing this challenge, the SNA sequence of economic accounts includes distributional accounts for the households sector that take into account the joint relationships between income, consumption and wealth. In turn this supports the computation of multivariate indicators (such as consumption-to-income, debt-to-income or wealth-to-income ratios) for the various breakdowns of the households sector. The description of distributional accounts for households in this Section complements the wider discussion of the use of accounting approaches to support the measurement of the material well-being of households introduced in Chapter 2 and discussed more fully in Chapter 34.

32.89 A motivation for the compilation of household distributional accounts is that while distributional information is often available from micro statistics, these results may not always be consistent across the primary components of material well-being (including income, consumption and wealth). In this regard, household surveys or administrative data covering all these aspects are rarely available. Further, these data may not always be consistent over time and their aggregated trends may often diverge from aggregate national accounts data. Section B.5 discusses these issues in more detail.

32.90 The compilation of household distributional accounts entails breaking down accounting entries for the aggregate household sector into more granular subsectors consisting of specific groups of households. This should be done for the sequence of economic accounts representing different types of economic activity occurring within a period of time, including balance sheets. This will lead to a consistent and comprehensive description of different groups

of households across the various accounts.

32.91 Thus, deriving household distributional information within the structure of the sequence of economic accounts enables the derivation of distributional results that are consistent across the various economic accounts and institutional sectors, coherent with macroeconomic aggregates and comparable over time and across countries. This information will be of considerable relevance for macroeconomic analyses and the monitoring of material well-being, providing new insight in how specific household groups are faring and assessing how macroeconomic trends and policies may affect specific household groups.

## **2. Establishing the focus of measurement**

32.92 As noted in Section B the household sector in the SNA includes both private and institutional households. The latter concern persons living permanently in an institution, or who may be expected to reside in an institution for a very long, or indefinite, period of time, with little or no autonomy of decision in economic matters. These types of households may comprise large groups of individuals with very different socio-demographic backgrounds, who are not related, and who may have very different income and consumption patterns. As a consequence, they behave differently and the data about their income, consumption and wealth is not readily comparable with those of private households. For that reason, it is recommended that institutional households are treated separately from private households in the compilation of household distributional accounts, i.e., that results for institutional households should be analysed and presented as a separate category. The focus of the description in this section is on distributional accounts for private resident households.

32.93 Approaches to incorporating institutional households to provide a complete scope for the sector may be considered, for example, treating the population living in the institutions as multiple, often single person, households. However, compilers and users need to be aware that this may not do justice to the specific circumstances these individuals live in. Furthermore, treating them as a single household comprising many individuals may lead to heterogeneous results and may distort distributional analyses.

32.94 Although the household constitutes the unit of observation in compiling distributional accounts, household units differ in size and composition, and as a consequence they will have different consumption needs. By way of example, the consumption opportunities from an income of 3,000 monetary units per month for a single person household are not comparable to those from an income of 3,000 monetary units for a household consisting of two adults and three children living at home. Therefore, to arrive at comparable results across households and support meaningful analysis of data on income, consumption and wealth at the household level, it is recommended to focus on 'equivalized' results, using equivalence scales that take into account differences in the size and composition of households. This involves recalculating initial estimates according to the number of consumption units in each household and then assigning a value to each household type in proportion to its needs reflecting its size and composition. Considerations in establishing equivalence scales are discussed below.

32.95 While approaches for estimating and applying equivalence scales for income and consumption are well developed, for wealth, there is less consensus on the appropriate equivalence scale. However, for consistency across domains, it is recommended to use the same equivalence scales to adjust wealth as those used to adjust income and consumption, when presenting results on income, consumption and wealth in conjunction. This recognizes that wealth may often be used to support current consumption. However, since wealth is a stock and not a flow measure, for specific purposes, it may be relevant to show results on the distribution of wealth on the basis of alternative equivalence scales.

32.96 A complete sequence of distributional accounts for households encompasses a large number of accounting entries. It is therefore relevant to focus attention on the derivation of the following main balancing items for the purposes of distributional analysis:

- For analyzing the distribution of household income, the relevant balancing items are 'earned income', 'disposable income' and 'disposable income adjusted for social transfers in kind'.
- For analyzing the distribution of household consumption, the relevant entries are 'final consumption expenditure' and 'actual final consumption'.
- For analyzing the distribution of household wealth, the relevant balancing items are 'net worth' and 'net financial worth'.

32.97 In addition, it is recognised that there are a range of alternative income concepts that may be of relevance for certain types of analysis. These are discussed in Chapter 34, Section B.2. Further, countries are encouraged to show estimates of consumer durables by household type as a separate category particularly as they may significantly affect savings results and provide insights into the distribution of household wealth. For wealth, a broader wealth concept could be envisaged that includes social security pension entitlements. These possible extensions are not discussed further in this section.

32.98 The groupings that should be used in selecting households to be the focus of the distribution accounts are those that:

- provide most insight in differences in consumption, income, and wealth patterns between groups;
- are of most interest for economic analysis and government policy purposes;
- enable users to easily identify themselves with one of the groups; and
- meet specific user demands.

32.99 Based on these criteria, the primary recommendation for the grouping of households is on the basis of deciles of equivalized household disposable income. This involves looking at the relative income available to a household, ranking households accordingly and allocating them into decile groups. Of course, a decile breakdown may still conceal large inequalities within these groups and hence further breakdowns into more granular groups may be considered. This may be particularly relevant for the top income and wealth groups. Thus, accounts for the top 5%, 1% and even 0.1% of income earners may be compiled.

32.100 Other household groupings that may be considered include those based on levels of permanent income, main source of income the age of the reference person and the composition of households. Section C and Chapter 34 provide additional discussion on the subsectoring of households and the range of characteristics of households and household members that can be considered in distributional accounting and analysis.

32.101 The compilation of household distributional accounts will generally be undertaken at discrete points in time providing a static view of distributions. A dynamic approach to the analysis of household distributions, i.e., comparing changes in distributions over time, will also be of relevance. Maintaining a standard conceptual structure and associated definitions for the distributional accounts provides a good basis for this analysis of change recognizing that there is a range of challenges in dynamic structural analysis that will need to be considered.

### **3. Compiling distributional accounts for households**

32.102 This section describes the basic approach for compiling distributional accounts in line with aggregate accounting entries in the sequence of economic accounts on the basis of underlying micro data sources. The application of the approach requires engagement and close collaboration with the experts in the relevant micro statistics. More detailed compilation guidance is available in the *Handbook of Distributional National Accounts* (OECD, 2023). Relevant information concerning the use of micro data is available in the international guidelines for measuring the distribution of household wealth in micro statistics (OECD, 2013), and the framework for the integrated analysis of micro data on household income, consumption and wealth (OECD, 2013).

32.103 There are five main steps in compiling distributional accounts for households:

1. Adjust national accounts aggregates to focus on private resident households
2. Select relevant micro data for the purposes of disaggregating macro accounting entries for each household subsector/group
3. Impute for missing elements and align micro-macro results
4. Cluster households according to household subsectors/groups
5. Derive relevant distributional and analytical indicators – e.g. ratio to the average, ratio of the highest to lowest shares, coefficient of variation to the average, share by household group, debt to income ratios, savings ratios by household group.

32.104 In undertaking these steps, the following accounting issues are noted, recognizing that there are a range of data

confrontation and compilation issues that must also be considered as detailed in the compilation guidance referred to above.

32.105 While the aggregate results for the household sector are a solid starting point for the compilation of distributional accounts, these aggregates may conceal information on inter-households flows and stocks. Although these stocks and flows may not be relevant from a macroeconomic perspective, they may be very relevant in deriving distributional results. Thus, even if for the household sector as a whole, these flows and stocks may cancel out, this need not be the case at the level of household groups. Some household groups may turn out to be net contributors/debtors, while other household groups may turn out to be net receivers/creditors. For that reason, it is important in the compilation process to explicitly acknowledge inter-household flows and stocks and if they are not already covered in the aggregates of the household sector, compilers should derive separate estimates. Particular stocks and flows of relevance include current transfers (e.g., remittances), capital transfers (e.g., bequests, inheritances), second-hand trade, and loans (including the related interest flows).

32.106 Some accounting entries are specific to the national accounts and do not have a corresponding item in micro data sources. Such accounting entries will require imputations to allow for a complete allocation to the relevant household in compiling distributional results. Particular entries of relevance include employers' imputed social contributions, investment income disbursements (e.g., for life and non-life insurance), implicit financial services on loans and deposits, estimates for the non-observed economy and social transfers in kind. On the financial side, it may also concern currency and pension entitlements.

32.107 In addition to specific challenges in the compilation of distributional accounts for income, consumption and wealth separately, there is also a general challenge of ensuring coherence across the sequence of economic accounts, in particular between the financial accounts and non-financial accounts. At an aggregate level there is commonly a large statistical discrepancy that will also need to be considered for the various household groups.

32.108 Different household groups may face different price levels. Further, households in specific regions may for example face higher prices than in other regions. If these issues are of relevance, correction may be made using regional prices thus supporting fairer comparisons of income levels across households living in different regions. More generally, household groups may experience price changes differently, depending on the composition of their consumption basket. For that reason, it would be appropriate to have relevant price indices for each household group that may be used to analyse changes in real adjusted disposable income per household group.

32.109 In the derivation of equivalence scales, a value is assigned to each household type in proportion to its needs, often depending on their age, but possibly also taking into account other socio-demographic characteristics, such as sex or gender, level of income, labour force status and home ownership. The value may also depend on the specific delineation of the income or consumption measure that is analysed. For example, if the analysis includes social transfers in kind, this may require a somewhat different assignment of number of consumption units to the individual household members than when these transfers are excluded.

32.110 Furthermore, the value of the consumption unit may depend on the composition of consumption expenditure of various households. Thus, equivalence scales that are appropriate for lower income households may be less appropriate for higher income households due to different consumption patterns. For that reason, equivalence scales may differ across countries, as well as within a country for households with different socio-demographic characteristics.

32.111 As it is virtually impossible to derive equivalence scales that take into account all the relevant underlying factors, distributional studies often apply a simplified scale. Although this may have some caveats, it ensures consistency and transparency towards users, and also facilitates the assessment of the impact of the equivalence scale on the results. There are three commonly used equivalence scales in international comparisons:

- the square root of household size that, as it states, derives the number of consumption units by taking the square root of number of persons in the household;
- the OECD scale that assigns a value of 1 to the first household member, of 0.7 to each additional adult (14+) and of 0.5 to each child (up to 13); and
- the modified OECD scale that assigns a value of 1 to the household head, of 0.5 to each additional adult member (14+) and of 0.3 to each child (up to 13).

32.8032.112 These equivalence scales are often used in the analysis of the distribution of both income and

consumption. With respect to wealth, the use of equivalence scales depends on the purpose of the analysis. The use of equivalence scales should be avoided when analysing the characteristics of individual components of wealth and distribution of net wealth. To control for different household structures, complementary analysis can be done on per capita basis. However, for the joint analysis of income, consumption and wealth, it is practical to use the same equivalence scales to adjust wealth as those used to adjust income and consumption. As mentioned above, in this case, wealth is treated as a source of future income streams that can be used to finance current consumption and contribute to current material well-being in the household (see also Section 7.3.6. of the OECD Guidelines on Micro Statistics on Household Wealth (OECD (2013))).

## Chapter 33: Transactions and positions between residents and non-residents (moved upwards, revised title)

### (OLD Chapter 26: The rest of the world accounts and links to the balance of payments)

Please note that the details on economic territory and residency have been moved to Chapter 5 of the 2025 SNA. These re-allocations have not been highlighted in the form of track changes.

#### A. Introduction

33.1 This chapter is about the relationship between the rest of the world sector in the SNA and the international accounts as described in ~~BPM6~~BPM7. It shows that the two manuals use the same macroeconomic framework, with the international accounts providing additional detail on aspects of particular relevance in international transactions or positions.

#### 1. The rest of the world ~~account~~accounts in the SNA

33.2 The international accounts, as described in BPM7, are compiled from the domestic economy perspective, which can be thought of as the sum of the transactions and positions with non-residents for each of the institutional sectors in the compiling economy. In the SNA, transactions between a resident unit and the rest of the world are recorded as if the units in the rest of the world were another sector of the economy.

~~33.233.3~~33.3 The production and generation of earned income accounts relate only to transactions within the national economy but flows in all other accounts potentially have an entry for the rest of the world. These entries are necessary to balance each row of the sequence of economic accounts but they do not enter the aggregate balancing items. For example, the difference between GDP and GNI derives from transactions for both ~~uses~~expenditures and ~~resources~~revenues recorded in the allocation of primaryearned income account where the ~~counter-party~~counterparty is a unit in the rest of the world. ~~If the counter-party entries for the rest of the world were also included, there would be no difference between the balancing items.~~

#### Current accounts

~~33.333.4~~33.4 Because the rest of the world ~~account is~~accounts are shown in this way, flows to the rest of the world are shown as ~~a use~~an expenditure by the rest of the world and flows from the rest of the world as ~~resources~~revenues. For example, exports are shown as ~~uses~~expenditures of the rest of the world and imports as ~~resources~~revenues from the rest of the world. Entries for imports and exports form part of the goods and services account in the SNA sequence of economic accounts.

~~33.433.5~~33.5 As well as entries for imports, exports and the items appearing in the allocation of primaryearned income account, there are potential transactions with the rest of the world to be recorded for all entries in the ~~secondary distribution of~~ income transfers other than social transfers in kind account and for the adjustment item for the net change in pension liabilities appearing in the use of income account.

~~33.533.6~~33.6 There are no entries for the rest of the world ~~account~~accounts for intermediate or final consumption (or for ~~fixed~~ capital formation) because the use made of the goods and services in another economy is not relevant for the national economy; only the total amount exported is.

~~33.633.7~~33.7 Although balancing items are not calculated in the SNA for the rest of the world ~~account~~accounts for each individual account, two balancing items relevant to the current accounts are important. The first is the external balance on goods and services, which is the difference between imports and exports. The second is the current external balance which is the sum of all ~~resources~~revenues coming from the rest of the world less all ~~uses~~expenditures going to the

rest of the world, including imports and exports. The current external balance thus shows how far residents call on saving by non-residents, or vice-versa.

## Accumulation accounts

33.733.8 In the rest of the world capital account, there is no entry for (fixed) capital formation, as noted above. It is possible for a transaction to be recorded for a natural resource, for a contract, lease or licence or for goodwill and marketing assets. By their nature, though, and given that land is almost always acquired by a resident unit, such entries will not be common. On the other hand, capital transfers to and from the rest of the world may be quite important.

33.833.9 The financial account and balance sheets detailing transactions in, and stocks of, financial assets and liabilities where one party is non-resident are viewed as a particularly important part of the rest of the world accounts. Indeed, in BPM6BPM7 more text is devoted to these items than to the items in the current accounts. In addition, there are possible entries for other changes in the volume of assets and liabilities and revaluation items for both, relevant to the rest of the world account.

## 2. The international accounts in BPM6BPM7

33.933.10 In the description of the rest of the world accounts above, it was noted that exports, for example, are treated as a-usean expenditure by the rest of the world and imports as a resourceerevenue from the rest of the world. As its name implies, the rest of the world account-isaccounts are drawn up from the perspective of the rest of the world. BPM6BPM7 looks at the same stocks and flows from the point of view of the domestic economy. Thus the BPM6BPM7 entries are the mirror image of the SNA entries relating to the rest of the world. Further, in the context of BPM6BPM7, stock levels are usually referred to as positions and the balance sheet accounts for all financial assets and liabilities where one party to the arrangement is non-resident is called the international investment position: (IIP).

33.1033.11 The international accounts for an economy summarize the economic relationships between residents of that economy and the rest of the world. They comprise:

- a. the balance of payments, which summarizes the current, capital and financial transactions between residents and non-residents during a specific time period;
- b. the international investment position (IIP), which shows at a point in time the value of: financial assets of residents of an economy that are claims on non-residents or are gold bullion held as reserve assets; and the liabilities of residents of an economy to non-residents; and
- c. the other changes in financial assets and liabilities account, a statement that shows other flows, such as valuation changes, which reconcile the balance of payments and IIP for a specific period by showing changes due to economic events other than transactions between residents and non-residents.

These accounts correspond to the transactions, balance sheets and other changes in assets accounts in the SNA, respectively. Note, though, that what appear as assets in the rest of the world accountaccounts appear as liabilities in the international accounts and vice versa.

## 3. The structure of the chapter

33.1133.12 Section B of the chapter discusses the accounting rules of the international accounts. These are consistent with the SNA accounting rules and agreement has been reached on when the SNA and when BPM6BPM7 takes the lead in defining the rules to be applied in both contexts. Residence is a case in point where the SNA follows BPM7, and this topic is discussed in Chapter 5. The structure of the international accounts and their relation to similar SNA accounts is the subject of section C.A feature of the financial accounts and IIP of the international accounts is the introduction of functional categories that describe the main purpose of financial investment abroad. This is the subject of section D. Section E touches on some considerations of particular importance to the international accounts; global imbalances, exceptional financing, debt reorganization, currency unions and currency conversions.

## B. Accounting principles

### 1. Comparison with SNA accounting principles

[33.1233.13](#) Although the SNA works with a quadruple-entry accounting system, the balance of payments has only a double-entry system. When a transaction is undertaken between two resident units, four entries are necessary, for example two showing the exchange of a good and two the exchange of a means of payment. However, when a resident unit carries out a transaction with a non-resident unit, national compilers are unable to verify independently the counterpart entries in the rest of the world account. As a result, although in principle the balance of payments is balanced, in practice, there may be an imbalance due to shortcomings in source data and compilation so that there is a mismatch between financial transactions and their counterparts within the domestic economy. This imbalance, a usual feature of published balance of payments data, is labelled ~~net errors and omissions~~ statistical discrepancy. The balance of payments manuals have traditionally discussed this item, to emphasize that it should be published explicitly, rather than included indistinguishably in other items and that it should be used to indicate possible sources of mismeasurement.

[33.1333.14](#) However, there has been increasing interest in estimates that are derived from counterpart reporting that has better coverage, valuation, etc. As well, there has been much work done on reconciling data from the view of both parties (for example, exports of one country, with the counterpart imports recorded by the partner country) and global totals. Counterparty data are also necessary to prepare consolidated data for a currency or economic union from the data of individual member countries. In effect, all this work is built on the fact that balance of payments statistics effectively become a quadruple-entry system when used at the bilateral or global level.

### Valuation

[33.1433.15](#) Valuation principles are the same in the SNA and the international accounts. In both cases, market values are used, with nominal values used for some positions in instruments where market prices are not observable. In the international accounts, the valuation of exports and imports of goods is a special case where a uniform valuation point is used, namely the value at the customs frontier of the exporting economy, that is, the FOB-type valuation (free on board). This treatment brings about consistent valuation between exporter and importer and provides for a consistent basis for measurement in circumstances where the parties may have a wide range of different contractual arrangements, from “ex-works” at one extreme (where the importer is responsible for arranging all transport and insurance) to “delivered duty paid” at the other (where the exporter is responsible for arranging all transport, insurance and any import duties). In international transactions, there may be motivations for under- or over-invoicing in order to evade taxes or exchange controls, so ~~BPM6~~ BPM7 provides guidance on how to develop market-equivalent prices when these cases are identified, and how to make the necessary adjustments needed to other items affected. Invoice values may become the new approach for valuing exports and imports in the future; see paragraphs 4.183 to 4.189 for a more detailed discussion. There is also further discussion on the recording of imports and exports in chapters 4415 and 2836.

### Time of recording and change of ownership

[33.1533.16](#) Time of recording and ownership principles are the same in the SNA and the international accounts. In practice, the change of economic ownership of goods is often taken to be when the goods are recorded in customs data. To the extent that there are differences between customs data and actual changes in ownership, such as for items with large values or goods sent on consignment (that is, dispatched before they are sold), adjustments are made.

[33.1633.17](#) There are no longer any exceptions to the recording basis of the change of economic ownership. However, there is a different presentation in the case of merchanting; that is, where an owner buys and resells goods in the same condition without the goods passing through the territory of the owner. In that case, the acquisition of the goods is identified as a change of ownership, but shown as a negative export rather than an import on acquisition of the goods and as a positive export on disposal. If the goods are acquired in one period and not disposed of until

a subsequent period, they will appear in changes in inventories of the merchant even though these inventories are held abroad. A consequence of this ~~change in~~ treatment is that in the international accounts, merchanting ~~now~~ appears as transactions in goods ~~where previously it was recorded as a transaction in services~~.

~~33.17~~33.18 The principle of recording imports and exports when change of ownership takes place applies also to items such as high-value capital goods where change of ownership is recorded as work is put in place. (See paragraphs 10.53 and 10.55.)

## Netting

~~33.18~~33.19 The same rules on netting are applied in ~~BPM6~~BPM7 as in the SNA. In general, netting is not advised except in the special case of recording transactions in financial assets and liabilities. However, only acquisitions and disposals of the same type of asset (or incurrence and redemption of the same type of liability) are netted. There is no netting of assets against liabilities, even of the same sort of instrument and no netting across different sorts of instruments. Greater detail about netting in respect of financial instruments appears in chapter ~~3 of BPM6~~, paragraphs ~~3.109 to 3.121~~8 of BPM7.

## 2. Units

~~33.19~~33.20 The international accounts and the SNA are built on the same definitions of institutional units and residence. Because the international accounts focus on economic relationships between residents and non-residents, more elaboration of borderline cases is provided in ~~BPM6~~BPM7. For a detailed discussion of economic territory and the residence of institutional units, see Chapter 5, Section 2.

## C. A comparison between the international accounts and the SNA rest of the world accounts

~~33.20~~33.21 Like the SNA, the international accounts cover accounts for current transactions, accumulation accounts and balance sheets. The transaction accounts are collectively called the balance of payments. An overview of the international accounts presentation (using the SNA numerical example) is given in tables ~~2633~~3. The three current accounts are the goods and services account, the ~~primary earned~~ income account and the ~~secondary transfer~~ income account. The ~~primary earned~~ income account corresponds to the allocation of ~~primary earned~~ income accounts in the SNA, the ~~secondary transfer~~ income account to the ~~secondary distribution of income~~ transfers other than social transfers in kind account in the SNA. The income accounts in ~~BPM6 do not use distribution and redistribution in their titles, since they do not show distribution and redistribution from one party to another, but~~BPM7 just show the income transactions from the point of view of one party. Because there is no account corresponding to use of income in the international accounts, the adjustment for the change in pension entitlements term appears as a single item after the ~~secondary~~ income transfers other than social transfers in kind account. ~~(Cross (cross-border pensions are currently relatively~~ minor for most economies~~)).~~

~~33.21~~33.22 There are no exact parallels in the international accounts for the production account, the generation of income account and use of income account because the international accounts do not describe production, consumption (or capital formation). Products imported and exported are treated as simple transactions in all cases; whether the products will eventually be used for intermediate consumption, final consumption, capital formation, or will be re-exported is unknown in the context of ~~the international~~ transaction~~transactions~~. The use made of products is ~~entirely~~ domestic in nature.

~~33.22~~33.23 Table ~~2633~~3 also shows the restricted form of the capital account in the international accounts ~~and as well as~~ the financial account using the functional classification of financial transactions rather than the instrument classification used in the SNA. Because the functional classification is a grouping of instruments, the two forms of presentation are strictly consistent. The functional classification is described below in section D. ~~(The, along with, the~~ explanation of the shaded cell for reserves liabilities ~~is explained in section D also).~~

## 1. Goods and services account

~~33.23~~33.24 The goods and services account consists only of imports and exports of goods and services because these are the only transactions in goods and services with a cross-border dimension. Goods and services are recorded when there is a change of economic ownership from a unit in one economy to a unit in another country. Although there is usually a physical movement of goods when there is a change of ownership, this is not necessarily the case. In the case of merchanting, goods may change ownership and not change location until they are resold to a third party.

**Table 26.3: Overview of the balance of payments**

~~33.1~~ ~~Goods that change location from one economy to another but do not change economic ownership do not appear in imports and exports. Thus goods sent abroad for processing, or returned after processing, do not appear as imports and exports of goods; only the fee agreed for processing appears as a service.~~

~~33.24~~33.25 The balance of payments gives emphasis to the distinction between goods and services. This distinction reflects policy interests, in that there are separate international treaties covering goods and services. It also reflects data issues, in that data on goods are usually obtained from customs sources, while data on services are usually obtained from surveys, payments records ~~or surveys and other administrative sources~~.

### Goods

33.26 The main source of data for goods is international merchandise trade statistics. International standards are given in *International Merchandise Trade Statistics: Concepts and Definitions (IMTS)* (United Nations, 1998). ~~BPM6~~Goods are presented at an aggregate level in the balance of payments, whereas more detailed commodity breakdowns can be obtained from IMTS data.

~~33.25~~33.27 BPM7 identifies some sources of difference that may occur in some or all countries. It also recommends a standard reconciliation table to assist users in understanding these differences. One major source of difference is that the standards for IMTS use a CIF-type (cost, insurance and freight) valuation for imports, while the balance of payments use a uniform FOB valuation for both exports and imports. It is therefore necessary to exclude freight and insurance costs incurred between the customs frontier of the exporter and the customs frontier of the importer. Because of variations between the FOB-type valuation and actual contractual arrangements, some freight and insurance costs need to be rerouted. Further details are provided in chapter 15.

33.28 The change of ownership basis used for the balance of payments means that goods entries will have a time of reporting consistent with the corresponding financial ~~flow~~transactions. In ~~BPM6~~BPM7, there are no ~~longer~~ exceptions to the change of ownership principle. In contrast, IMTS follow the timing of customs processing. While this timing is often an acceptable approximation, adjustments may be needed in some cases, such as goods sent on consignment.

33.29 ~~Goods that change location from one economy to another but do not change economic ownership, while part of merchandise trade, do not appear in imports and exports in the balance of payments or SNA. Thus, goods sent abroad for processing, and returned after processing, do not appear as imports and exports of goods; only the fee agreed for processing appears as a service.~~ In the case of goods sent abroad for processing with no change of ownership, the values of goods movements are included in IMTS, but changes in ownership are the primary presentation in the balance of payments. ~~(However, the values of goods movements are recommended as supplementary items to understand the nature of these arrangements-).~~ Further details of the recording of these processing arrangements are given in chapter 23 ~~(see paragraphs 23.21- to 23.27).~~

~~33.26~~33.30 Other adjustments to IMTS may be needed to bring estimates into line with the change of economic ownership of goods, either generally or because of the particular coverage of each country. Possible examples include merchanting, inverse merchanting, non-monetary gold, goods entering or leaving the territory illegally, goods procured in ports by carriers, and goods moving physically but where there has been no change of ownership.

### Merchanting

33.31 Merchanting involves the purchase of goods by a resident (of the compiling economy) from a non-resident and the subsequent resale of the goods to another non-resident. Under such arrangements, the goods do not cross the border of the compiling economy, at any point, but the goods change ownership. The purchase is recorded as negative exports and the subsequent sale as positive exports, with the difference representing the trade margin of the merchant. Further details of the recording of merchanting are given in chapter 23 (see paragraphs 23.12 to 23.20).

### Factoryless goods arrangements

33.32 International sales of final goods under factoryless goods producer (FGP) arrangements are recorded under goods (general merchandise) and not under merchanting. The activity of the FGP is manufacturing. Further details of the recording of this activity are given in chapter 23 (see paragraphs 23.28 to 23.32).

### Re-exports

33.2733.33 Re-exports are foreign goods (goods produced in other economies and previously imported with a change of economic ownership) that are exported with no substantial transformation from the state in which they were previously imported. Because re-exported goods are not produced in the economy concerned, they have less connection to the economy than other exports. Economies that are major trans-shipment points and locations of wholesalers often have large values of re-exports. Re-exports increase the figures for both imports and exports; and, when re-exporting is significant, the proportions of imports and exports to economic aggregates ~~are increased~~ also increase. It is therefore useful to show re-exports separately. Goods that have been imported and are waiting to be re-exported are recorded in inventories of the resident economic owner.

~~33.233.1 Goods are presented at an aggregate level in the balance of payments. More detailed commodity breakdowns can be obtained from IMTS data.~~

### ~~Detail~~Services

33.34 Standards for services trade are shown in the *Manual on Statistics of International Trade in Services (MSITS)* (United Nations, European Commission, International Monetary Fund, Organisation for Economic Co-operation and Development, United Nations Conference on Trade and Development and the World Trade Organization, 2010), which is fully harmonized with the international accounts.

33.35 As noted above, goods sent abroad for processing, and returned after processing, do not involve a change of ownership, and are thus not recorded as imports and exports of goods. Instead, the fees for processing appear as either imports of services (payments for processing) or exports of services (receipts from processing), and are included in item (a) below.

33.2833.36 Trade in services detail is produced for the following ~~42~~16 standard components of services:

- a. Manufacturing services on physical inputs owned by others;
- b. Maintenance and repair services n.i.e.;
- c. Transport;
- d. Travel;
- e. Construction;
- f. Insurance and pension services;
- g. Financial services;
- h. Charges for the use of intellectual property n.i.e.;

- ~~i.~~ i. Telecommunications, ~~computer services~~
- ~~i.j.~~ j. Computer and information services;
- ~~j.k.~~ k. Research and developments services
- ~~k.l.~~ l. Professional and management consulting services
- ~~l.m.~~ m. Trade-related services
- ~~m.n.~~ n. Operating lease services
- ~~n.o.~~ o. Technical and other business services;
- ~~o.p.~~ p. Personal, cultural and recreational services; and
- ~~p.q.~~ q. Government goods and services n.i.e.

~~33.29~~33.37 ~~Three~~Most components of trade in services are product-based, derived from the more detailed classes of CPC 2.1. However, ~~three~~ of the standard components are transactor-based items, that is, they relate to the acquirer or provider, rather than the product itself. These categories are travel, construction and government goods and services n.i.e.

~~33.30~~33.38 Travel covers all goods or services acquired by non- residents during visits whether for own use or to give away. Travel includes goods, local transport, accommodation, meals and other services. Construction covers both the total value of the product delivered by the contractor and any goods and services sourced locally by the contractor that are not recorded in imports and exports of goods. Government goods and services n.i.e. cover a range of items that cannot be allocated to more specific headings.

~~33.31~~ ~~Besides the three transactor based items, the remaining components are product based, built from the more detailed classes of the CPC 2. Additional standards for services trade are shown in the Manual on Statistics of International Trade in Services (MSITS) (United Nations, European Commission, International Monetary Fund, Organisation for Economic Co-operation and Development, United Nations Conference on Trade and Development and the World Trade Organization, 2002), which is fully harmonized with the international accounts.~~

## 2. The primary earned income account

~~33.32~~33.39 The entries in ~~the primary income~~this account are concerned with ~~compensation~~remuneration of employees and property income, exactly as in the allocation of primary earned income account in the SNA. Payments of taxes on production by residents and receipts of subsidies by residents from the domestic government are recorded in the generation of income account, an account that does not form part of the balance of payments. Any payments of taxes on production payable by a resident to another government as well as any subsidy receivable by a resident from another government are recorded in the primary earned income account of the balance of payments. The matching entries for the domestic government are shown in the SNA in the allocation of primary earned income account and for foreign governments in the rest of the world column of that account and in the primary earned income account of the balance of payments.

~~33.33~~33.40 Rent relates to the income receivable by the owner of a non-produced non-financial asset (the lessor or landlord) for putting the asset at the disposal of another institutional unit (a lessee or tenant) for use in production. Examples concern payments related to the use of marketing assets, land and other non-produced natural resources. Rent on land and other natural resources may arise in cross-border situations, but rarely, because all land and other natural resources are deemed to be owned by residents, if necessary by creating a notional resident unit. An example where rent on natural resources may be recorded in the international accounts may be short-term fishing rights in territorial waters provided to foreign fishing fleets. It is common in the international accounts to use the term investment income meaning property income excluding rent. Investment income therefore reflects income arising from the ownership of financial assets and the disaggregation of investment income matches that of financial assets and liabilities so that rates of return can be calculated.

~~33.34~~33.41 In ~~BPM6, BPM7, flows of interest flows and similar returns~~ are measured on exactly the same basis as in the SNA with ~~FISIM implicit financial services on loans and deposits~~ separated and treated as an import or export of financial services.

## Income of direct investment enterprises

~~33.35~~33.42 The role of direct investment enterprises is particularly important and reflected in both the flows and positions in the international accounts. There is extended discussion on the identification and role of direct investment enterprises in section D.

~~33.36~~33.43 As explained in paragraphs ~~7.136-8.141~~ to ~~7.139, 8.144~~, in the case of a direct investment enterprise, it is assumed that a proportion of the enterprise's retained earnings is distributed to the direct investor as a form of investment income. The proportion corresponds to the direct investor's holding in the enterprise.

~~33.37~~33.44 Retained earnings are equal to the net operating surplus of the enterprise plus all property income earned less all property income payable (before calculating reinvested earnings) plus current transfers receivable less current transfers payable and less the item for the adjustment for the change in pension entitlements. Reinvested earnings accrued from any immediate subsidiaries are included in the property income receivable by the direct investment enterprise.

~~33.38~~33.45 Reinvested earnings may be negative, for example where the enterprise makes a loss or where dividends are distributed from ~~holding gains, accumulated earnings~~, or in a quarter when an annual dividend is paid. ~~However, if In this respect, it can be noted that payments related to the dividends sales of financial or non-financial assets are disproportionately large relative to recent levels of dividends and earnings, the excess should be recorded treated~~ as a withdrawal of owner's equity. ~~The treatment of dividends for foreign direct investment differs from the corporation as explained in paragraph 7.131, treatment of those for domestic direct investment; see paragraphs 8.136 and 8.137.~~

~~33.39~~33.46 For a direct investment enterprise that is 100 per cent owned by a non-resident, reinvested earnings are equal to retained earnings and the net saving of the enterprise is exactly zero.

## 3. Secondary Transfer income account

~~33.40~~33.47 The entries in ~~the secondary income this~~ account are current transfers. The range of entries corresponds exactly to those in the ~~secondary distribution of income~~ transfers other than transfers in kind account in the SNA. Several of these are particularly important in the international accounts, especially current international cooperation and remittances sent to their home countries by individuals working abroad.

~~33.41~~33.48 Cross-border personal transfers are household-to-household transfers and are of interest because they are an important source of international funding for some countries that provide large numbers of long-term workers abroad. Personal transfers include remittances by long-term workers, that is, those who have changed their economy of residence.

~~33.42~~33.49 Other workers, such as border and seasonal workers do not change their economy of residence from the home economy. Instead of transfers, the international transactions of these workers include ~~compensation~~ remuneration of employees, taxes and travel costs. A supplementary presentation of personal remittances brings together personal transfers with these related items. Personal remittances include personal transfers, ~~compensation~~ remuneration of employees less taxes and travel, and capital transfers between households. For further details, see Appendix ~~5x~~ Remittances in ~~BPM6 BPM7~~.

~~33.43~~33.50 Insurance flows, especially flows relating to reinsurance, can be important internationally. These flows are recorded in the same way as in the SNA, both as regards the separation of a financial service charge and the treatment of direct insurance and reinsurance flows separately and not on a consolidated basis. Detailed information on this separation is given in part 1 of chapter ~~47~~24.

#### 4. Balancing items in the current accounts of the international accounts

[33.4433.51](#) The structure of the balancing items in the balance of payments is somewhat different from that in the SNA, in that each account has its own balancing item and another that carries down to the next account. To illustrate, the primary earned income account has its own balancing item (balance on primary earned income) and a cumulative balance (balance on goods, services and primary earned income). The external balance on primary earned income corresponds to balance of primary incomes this account and is the item feeding into GNI. The current external balance corresponds to saving by the rest of the world relative to the domestic economy. The balancing items in the BPM6BPM7 structure of accounts are shown in table 4619.3, reproduced here for convenience as table 2633.4.

#### 5. The capital account

[33.4533.52](#) The elements of the capital account subject to international transactions are more restricted than those covered in the SNA. The entries Transactions in produced assets are not recorded in the capital account—ever, because, as explained earlier, they are recorded as exports and imports of goods (and possibly services). Therefore, the capital account only includes acquisitions and disposals of non-produced non-financial assets and capital transfers. There are no transactions recorded as capital formation of produced assets because, as explained earlier, the ultimate use, including unusually large non-life insurance claims and other major compensatory payments, capital taxes, investment grants, debt forgiveness and one-off guarantees and other types of exports is not a concern for the national economy—debt assumption.

[33.4633.53](#) Like the SNA, net lending or net borrowing is the balancing item for the sum of the current and capital accounts and for the financial account. As in the SNA, it covers all instruments used for providing or acquiring funding, not just lending and borrowing. Conceptually, it has the same value as the national accounts item for the total economy, and the same as the national accounts item for the rest of the world but with the sign reversed.

#### 6. The financial account and IIPinternational investment position

[33.4733.54](#) The financial account of the balance of payments and the IIPinternational investment position (IIP) are of particular importance because they provide an understanding of international financing as well as of international liquidity and vulnerability. The integrated IIP statement, including parallels the accumulation accounts in the SNA, as shown in Table 33.5. It combines the opening and closing balance sheet positions of the IIP and associated with the financial and transactions, the other changes accounts, is shown in Table 26.5. The primary classification is based on functional categories, with additional data on instruments in volume of assets and liabilities, and institutional sectors—revaluations.

[33.4833.55](#) Financial transactions and positions with non-residents are presented in the SNA on an asset and liability basis, by instrument. However, the primary classification of the international accounts is based on functional categories. The functional categories, described in section D, convey more information about the motivation and relationship between the parties, which are of particular interest ~~to~~for international economic analysis. ~~Data by~~The functional ~~category~~categories are further subdivided by instrument and institutional sector, which makes it possible to link them to the corresponding SNA and monetary and financial statistics items. The institutional sector classification is the same as in the SNA, although it is usually abbreviated (to five sectors in the standard components). In addition, a supplementary subsector is used for monetary authorities, which is a functional subsector linked to reserve assets. It covers the central bank and any parts of general government or financial corporations other than the central bank that hold reserve assets, so it is relevant for countries where some or all reserves are held outside the central bank.

**Table 2633.4: Balancing items in the international accounts in relation to the SNA sequence of economic accounts**

[33.4933.56](#) The part of the balance sheets covered in the international accounts is called the IIP. The terminology

highlights the specific components of the national balance sheet which are included. The IIP covers only financial assets and liabilities because, to be included in the IIP, there must be a cross-border element. In the case of financial claims, the cross-border element arises when one party is a resident and the other party is a non-resident. In addition, while gold bullion is an asset that has no counterpart liability, it is included in the IIP when held as a reserve asset, because of its role as a means of international payments. However, non-financial assets are excluded as they do not have a counterpart liability or other international aspect.

~~33.50~~33.57 The balancing item on the IIP is the net IIP. The net IIP plus non-financial assets in the national balance sheet equal national net worth, ~~because~~with all resident-to-resident financial claims ~~net to zero~~accounted for in the national balance sheet.

~~33.51~~33.58 The same level of detail is used for investment income and the IIP. As a result, average rates of return can be calculated. Rates of return can be compared over time and for different instruments and maturities. For example, the trends in return on direct investment can be analysed, or the return can be compared with other instruments.

## 7. The other changes in assets accounts

~~33.52~~33.59 International assets and liabilities may be subject to all the possible types of other changes in the volume of assets and liabilities and to revaluation changes. For example, entries are made in the other changes in volume of assets and liabilities account for monetization and de-monetization of gold, or for the unilateral cancellation of a claim by a debtor. Because instruments are often denominated in foreign currencies and analysis of the effect of exchange rate movements is particularly important, ~~there is a~~the breakdown of revaluations into exchange rate changes and other factors is essential for analysis.

## D. International accounts functional categories

~~33.53~~33.60 The international accounts functional categories are the primary classification used for each of investment income, financial transactions and positions in the international accounts. The following five categories are identified:

- a. direct investment;
- b. portfolio investment;
- c. financial derivatives (other than reserves) and employee stock options;
- d. other investment; and
- e. reserve assets.

**Table ~~26~~33.5: Overview of Integrated International Investment Position Statement**

~~33.54~~33.61 Detailed definitions are given later in this section. The functional categories are built on the classification of financial instruments discussed in chapters ~~4+12~~ and ~~4+14~~, but with an additional dimension that takes into account some aspects of the relationship between the parties and the motivation for investment. As a result, the different categories exhibit different patterns of behaviour. For example, there is a different type of relationship between the parties for direct investors compared to portfolio investors holding equity. Direct investment is related to control or a significant degree of influence, and tends to be associated with a lasting relationship although it may be short-term. In addition to financial resources, direct investors often supply additional factors such as know-how, technology, management and marketing. As well, related companies are more likely to trade with and lend to each other. In contrast, portfolio investors typically have a smaller role in the decision-making of the enterprise, with potentially important implications for future flows, and for the volatility of the price and volume of positions. Portfolio investment differs from other investment in that it provides a direct way to access financial markets, and so can provide liquidity and flexibility.

[33.5533.62](#) Reserve assets include a range of instruments that are shown under other categories when not owned by monetary authorities or other units authorized by the monetary authorities and sometimes even when held by monetary authorities. However, as reserve assets they are identified as being available to meet international payments financing needs and undertake market intervention to influence the exchange rate.

[33.5633.63](#) The instrument classification alone does not fully reflect these behavioural differences. For example, a loan can appear under direct investment or other investment, but the different nature of the relationship between the parties means that the risks and motivations behind the transaction tend to differ. A direct investment loan is more likely to be provided and generally involves less vulnerability on the part of the borrowing economy because of the relationship between the parties. Table [2633.6](#) shows the relationship between instruments and functional categories.

**Table [2633.6](#): Link between Financial Assets Classification and Functional Categories**

Footnote 1: SDR assets are reserve assets; SDR liabilities are other investment;

X shows applicable functional categories; x shows cases that are considered to be relatively uncommon.

## 1. Direct investment

[33.5733.64](#) *Direct investment is a category of cross-border investment associated with a resident in one economy having control or a significant degree of influence on the management of an enterprise that is resident in another economy.* As well as the equity that gives rise to control or influence, direct investment also includes associated debt (except debt between affiliated financial intermediaries).

[33.5833.65](#) Control is determined to exist if the direct investor owns more than 50 per cent of the voting power in the direct investment enterprise. Such an enterprise is called a subsidiary. A significant degree of influence is determined to exist if the direct investor owns from 10 to 50 percent of the voting power in the direct investment enterprise. Such an enterprise is called an associate. In order to achieve bilateral consistency and avoid subjective decisions about actual control or influence, these operational definitions should be used in all cases.

[33.5933.66](#) As well as immediate direct investment relationships, there may be indirect direct investment relationships, as a result of a chain of ownership. In addition, fellow enterprises may be an important part of direct investment. (Fellow enterprises are enterprises that have less than ten per cent equity in each other but which are under the control or influence of the same investor who is a foreign direct investor in at least one of the fellows.) Reverse investment arises when direct investment enterprises invest in their own direct investors but have less than ten per cent of the voting power in the direct investor.

[33.6033.67](#) Direct investment includes debt between the parties as well as equity except in the case of debt positions between related financial institutions: [\(e.g., insurance companies and pension funds\)](#). Such debt between related companies may be called inter-company lending. One of the features of a group of direct investment enterprises is that its members are more likely to extend loans and trade credit to each other than are unrelated enterprises.

[33.6133.68](#) Because of the relationship of control or influence, the direct investor's share of retained earnings of a subsidiary or associate is imputed as first being paid out as an income flow and then reinvested as a financial transaction. The income item is called reinvested earnings; the corresponding equal entry in the financial account is called reinvestment of earnings. Reinvested earnings are defined as the direct investor's share in the retained earnings of the enterprise, and so are consistent with the corresponding SNA items. A consequence is that there will be no net saving by an enterprise that is 100 per cent foreign owned, because all saving will be attributed to its direct investor.

[33.6233.69](#) Those direct investment enterprises that are controlled by non-residents correspond to the SNA subsectors of foreign- controlled enterprises. However direct investment enterprises include those not subject to control from abroad but still subject to a significant degree of influence. The SNA's foreign-controlled enterprises are limited to inward direct investment, while the international accounts are also concerned with outward direct investment.

Reinvested earnings on foreign direct investment in the SNA have the same scope as in the balance of payments (although “foreign” is not used because it is redundant in the context of the international accounts).

[33.6333.70](#) In addition to the statistics on the international financial flows associated with direct investment, information on foreign-controlled enterprises is provided through statistics on the Activities of Multinational Enterprises (AMNE statistics) and the closely related Foreign Affiliates Statistics (FATS). These cover items such as exports, imports, domestic sales and domestic purchases of goods and services, labour input and value added. They therefore provide a wider picture of the operations of multinational enterprises. Additional information is available in *Recommendations Manual on the Production of Foreign Affiliates Statistics*, the *Handbook on Economic Globalisation Indicators* and *MSITS*.

## 2. Portfolio investment

[33.6433.71](#) *Portfolio investment is defined as cross-border transactions and positions involving debt or equity securities, other than those included in direct investment or reserve assets.* Securities are instruments designed for convenient negotiability between parties, such as shares, bonds, notes and money market instruments. The negotiability of securities is a way of facilitating trading, allowing them to be held by different parties during their lives. Negotiability allows investors to diversify their portfolios and to withdraw their investment readily.

[33.6533.72](#) Portfolio investment typically depends on organized financial markets and associated bodies such as dealers, exchanges and regulators. In contrast, the parties to direct and other investment instruments usually deal directly with each other. The negotiability of portfolio investment transactions makes them a convenient and flexible investment channel, but also may be associated with volatility.

## 3. Financial derivatives (other than reserves) and employee stock options

[33.6633.73](#) The definition of the functional category financial derivatives (other than reserves) and employee stock options largely coincides with the corresponding financial instrument class, discussed in chapters [12](#), [14](#) and [25](#). The difference in coverage between the functional category and the financial instrument is that financial derivatives associated with reserve asset management are excluded from the functional category and included in reserve assets. This category is identified separately because it relates to risk transfer, rather than supply of funds or other resources.

## 4. Other investment

[33.6733.74](#) *Other investment is a residual category that includes positions and transactions other than those included in direct investment, portfolio investment, financial derivatives and employee stock options and reserve assets.* It includes the remainder of the following financial instruments:

- a. other equity;
- b. currency and deposits;
- c. loans (including use of IMF credit and loans from the IMF);
- d. non-life insurance technical reserves, life insurance and annuities entitlements, pension entitlements and provisions for calls under standardized guarantees;
- e. trade credit and advances;
- f. other accounts receivable/payable; and
- g. SDR allocations (SDR holdings are included in reserve assets).

## 5. Reserve assets

[33.6833.75](#) *Reserve assets are those external assets that are readily available to and controlled by monetary*

*authorities for meeting balance of payments financing needs, for intervention in exchange markets to affect the currency exchange rate and for other related purposes (such as maintaining confidence in the currency and the economy, and serving as a basis for foreign borrowing). Reserve assets must be denominated and settled in foreign currency.* Underlying the concept of reserve assets are the notions of “control” and “availability for use” by the monetary authorities. The standardized statistical definition of net international reserves is reserve assets less short-term net foreign currency claims.

33.6933.76 In general, only external claims actually owned by the monetary authorities can be classified as reserve assets. Nonetheless, ownership is not the only condition that confers control. In cases where institutional units (other than the monetary authorities) in the reporting economy hold legal title to external foreign currency assets and are permitted to do so only on terms specified by the monetary authorities or only with their express approval, such assets can be considered reserve assets. This is because such assets are under the direct and effective control of the monetary authorities.

33.7033.77 Reserve assets must be readily available in the most unconditional form. A reserve asset is liquid in that the asset can be bought, sold and liquidated for foreign currency (cash) with minimum cost and time, and without unduly affecting the value of the asset. This concept refers to both non-marketable assets, such as demand deposits, and marketable assets, such as securities where there are ready and willing sellers and buyers. In order to be readily available to the authorities to meet balance of payments financing needs and other related purposes under adverse circumstances, reserve assets generally should be of high quality.

33.7133.78 Reserve assets are limited to assets, but a memorandum item is provided for reserve-related liabilities that are included in other functional categories, mainly portfolio and other investment. (This is why the liabilities cell for reserves in table 26.3 is shaded.)

## **E. Special international accounts considerations**

### **1. Global imbalances**

33.7233.79 In recent years, the IMF has done extensive work on global statistical imbalances. By summing data on transactions (goods, services, transfers, etc.) and (changes in) financial stocks between residents and non-residents for all economies, global totals can be derived. (Although as a functional category, reserve assets have no counterpart liability, the constituent instruments can be allocated to their counterpart liabilities for an exercise of the type described here.) The extent of actual inconsistency has been used to identify systematic biases that can indicate reporting problems, for example, that services credits have higher coverage than services debits.

### **2. Exceptional financing**

33.7333.80 Exceptional financing brings together financial arrangements made by the authorities to meet balance of payments needs. Exceptional financing therefore identifies transactions according to their motivation. In addition, the incurrence of arrears is included in exceptional financing. Although it is not a transaction, it is an action the monetary authorities may take to manage their payments requirements.

33.7433.81 Exceptional financing is presented in the “analytic” presentation of the balance of payments, as published in the Balance of Payments Statistics Yearbook (International Monetary Fund, annual). In this presentation, entries relating to reserves, IMF credit and exceptional financing are presented “below-the-line” while all the other entries, which will require funding, are shown above-the-line. This presentation facilitates analysis of the monetary authorities’ international liquidity.

33.7533.82 There is more discussion on exceptional financing in appendix 1 of BPM6BPM7.

### **3. Debt instruments**

33.7633.83 It is useful to group the different types of debt instruments, because debt instruments have particular

implications for international liquidity and risk. Debt instruments are those instruments that require the payment of principal or interest or both at some point(s) in the future. Debt instruments comprise special drawing rights, currency and deposits, debt securities, loans, insurance technical reserves and provision for calls under standardized guarantees, and other accounts receivable/payable. Financial derivatives are not debt instruments, but an overdue obligation on a financial derivative contract is classified as an account payable and thus is included as a debt instrument.

[33.7733.84](#) Debt instruments can be contrasted with equity and investment shares in the nature of the liability and risk. While equity gives a residual claim on the assets of the entity, a debt instrument involves an obligation to pay an amount of principal or interest or both usually according to a predefined formula, which means that the creditor has a more limited risk exposure. In contrast, the return on equity is largely dependent on the economic performance of the issuer, so the holders bear more of the risk. Additional information is provided in the External Debt Guide.

[33.7833.85](#) Debt instrument flows and positions are shown divided between long-term and short-term. Primarily, this split is according to their original maturity, that is, the period from issue until contractually scheduled final payment. In addition, because of the international accounts concern with international liquidity issues, liability data can also be prepared on the basis of remaining maturity, that is, the period from the reference date until contractually scheduled final payment, on a supplementary basis.

#### 4. Debt reorganization

[33.7933.86](#) *Debt reorganization (also referred as debt restructuring) is defined as arrangements involving both the creditor and the debtor (and sometimes third parties) that alter the terms established for servicing an existing debt.* Governments are often involved in debt reorganization, as a debtor, or a creditor or a guarantor, but debt reorganization can also involve the private sector, such as through debt exchanges. Debt reorganization involves a range of different types of transactions as well as valuation and timing issues.

[33.8033.87](#) The four main types of debt reorganization are:

- a. Debt forgiveness; a reduction in the amount of, or the extinguishing of, a debt obligation by the creditor via a contractual arrangement with the debtor;
- b. Debt rescheduling or refinancing; a change in the terms and conditions of the amount owed, which may or may not result in a reduction in burden in present value terms;
- c. Debt conversion; the creditor exchanges the debt claim for something of economic value, other than another debt claim on the same debtor, such as debt-for-equity swaps, debt-for-real-estate swaps, debt-for-development swaps, debt-for-nature swaps, and for debt prepayments, debt-for-cash; and
- d. Debt assumption and debt payments on behalf of others when a third party is also involved.

Debt forgiveness across economies often involves government and there is further guidance on the treatments of these arrangements in chapter 22, [BPM6BPM7](#) and specialized manuals such as the *External Debt Guide*.

[33.8133.88](#) Debt repudiation, write-offs and write-downs of debt on a unilateral basis are not treated as transactions in either the SNA or [BPM6BPM7](#) and so are not considered part of debt reorganization.

#### 5. Regional arrangements, including currency unions

[33.8233.89](#) Regional arrangements include:

- a. monetary and currency unions, which provide for a single monetary policy across an area. Some of the same issues apply when one economy unilaterally adopts the currency of another economy, such as with “dollarization”;

- b. economic unions, which harmonize certain economic policies to foster greater economic integration; and
- c. customs unions, which have common tariff and other trade policies with non-member economies.

[33.8333.90](#) [BPM6BPM7](#) gives detailed guidance on the treatments of these arrangements. Among the issues that are dealt with are the production of consolidated data for a union as a whole, the treatment of regional organizations, including the central bank, treatment of bank notes in a currency union, and revenue-sharing arrangements in a customs union. The existence of a currency union central bank (common currency and single monetary policy) does not preclude the existence of country central bank institutional units within the union. The country's central bank institutional units are deemed to be resident institutional units in the economies where they are located. However, the residence of the currency union central bank is the region to which the union applies.

## 6. Currency conversion, including multiple exchange rates

[33.8433.91](#) Exchange rates must be considered carefully when measuring international transactions and positions, as changes can distort measurement. Flows denominated in a foreign currency are converted to their value in the domestic currency at the rate prevailing when the flows take place, and positions are converted at the rate prevailing on the balance sheet date. The midpoint between the buying and selling rates should be used at the time of transaction (for transactions) and at the close of business on the reference date for positions. The difference between buying/selling prices and midpoint prices represents a service charge and should be recorded as such.

[33.8533.92](#) In principle, the actual exchange rate applicable to each transaction should be used for currency conversion. The use of a daily average exchange rate for daily transactions usually provides a very good approximation. If daily rates cannot be applied, average rates for the shortest period should be used. Some transactions occur on a continuous basis, such as the accrual of interest, over a period of time. For such flows, therefore, an average exchange rate for the period in which the flows occur should be used for currency conversion.

[33.8633.93](#) Under a multiple exchange rate regime, two or more exchange rates are applicable to different categories of transactions; the rates favour some categories and discourage others. Such rates incorporate elements similar to taxes or subsidies. Because the multiple rates influence the values and the undertaking of transactions expressed in domestic currency, net proceeds implicitly accruing to authorities as a result of these transactions are calculated as implicit taxes or subsidies. The amount of the implicit tax or subsidy for each transaction can be calculated as the difference between the value of the transaction in domestic currency at the actual exchange rate applicable and the value of the transaction at a unitary rate that is calculated as a weighted average of all official rates used for external transactions. For conversion of positions of external financial assets and liabilities in a multiple rate system, the actual exchange rate applicable to specific assets or liabilities at the beginning or end of the accounting period is used.

[33.94](#) Parallel (unofficial) or black market rates cannot be ignored in the context of a multiple rate regime and can be treated in different ways. For instance, if there is one official rate and a parallel market rate, the two should be handled separately. Transactions in parallel markets should be converted using the exchange rate applicable in that market. If there are multiple official rates and a parallel rate, the official rates and the parallel rate should be treated as distinct markets in any calculation of a unitary rate. Transactions effected at the parallel rate usually should be separately converted at that rate. However, in some instances, parallel markets may be considered effectively integrated with the official exchange rate regime. Such is the case when most or all transactions in the parallel market are sanctioned by the authorities or when the authorities actively intervene in the market to affect the parallel rate, or do both. In this instance, the calculation of the unitary rate should include both the official and parallel market rates. If only limited transactions in the parallel market are sanctioned by the authorities, the parallel rate should not be included in the calculation of a unitary rate.

## Chapter 34: Measuring well-being

(new chapter)

### A. Introduction

34.1 Improving and sustaining the well-being of people and communities is the key focus across the majority of policy areas of government. As introduced in Chapter 2, in terms of the role of the SNA in assessing well-being, 'well-being' refers to the current material well-being of households. Within the scope of material well-being are measures of household income, consumption and wealth, labour and work (including unpaid household service work), education, health care and housing. The measurement of the sustainability of material well-being, including the extent to which the needs of current and future generations are satisfied is discussed in Chapter 35.

34.1.2 As introduced in Chapter 2, there are four aspects of most relevance in framing the measurement of the well-being of present and future generations may be considered in a number of ways. Three aspects are of most relevance. First, the goods and services consumed by people as recorded in measures of household actual final consumption<sup>1</sup>, including the consumption of goods produced for own-use and from the informal economy. Second, the goods and services consumed by people that are outside the scope of the SNA production boundary. These will include unpaid household service work, and non-market goods and ecosystem services sourced from the environment, and as well as the connections and relationships people hold with each other and with the environment. Third, people's functioning and capabilities – i.e., the freedom and possibilities they have to satisfy their needs. Fourth, the distribution of well-being across different groups within the population.

34.3 The links between these aspects of well-being are depicted in Figure 34.1. The inner circle first column concerns measures related to material well-being that are fully within scope of the SNA sequence of economic accounts, including its production and asset boundary, in particular net national income (NNI), household disposable income (HDI), and household actual final consumption, and including also data on the distribution of household income, consumption and wealth.

34.4 The middle circle second column focuses on those measures aspects of material well-being whose measurement that are incorporates extended accounting treatments using data from outside the scope of the SNA sequence of economic accounts, but which often have direct for which extended accounting treatments have been developed such that connections to data within the the sequence of economic accounts can be made. These aspects is set of measures includes unpaid household service work and ecosystem services. Collectively these two circles are described in the SNA as reflecting economic well-being.

34.2.34.5 The outer circle third column lists includes a range of other measures aspects which are commonly considered in the assessment of well-being, but which are out of scope of the discussion of material well-being within the context of national accounts. This includes measures of health outcomes such as life-expectancy and quality adjusted life years, measures of social cohesion, crime and justice, and measures of subjective well-being.

34.6 The boundary between the second and third middle and outer columns is are circle portrayed shown as a dashed line to indicate that t(a) a definitive measurement boundary on economic-material well-being has not been established. At the same time, it is recalled that the SNA has a focus on the measurement of outputs from economic activity rather than outcomes. As a result, the SNA does not organize data that supports direct measurement of, for example, the quality of life of households.

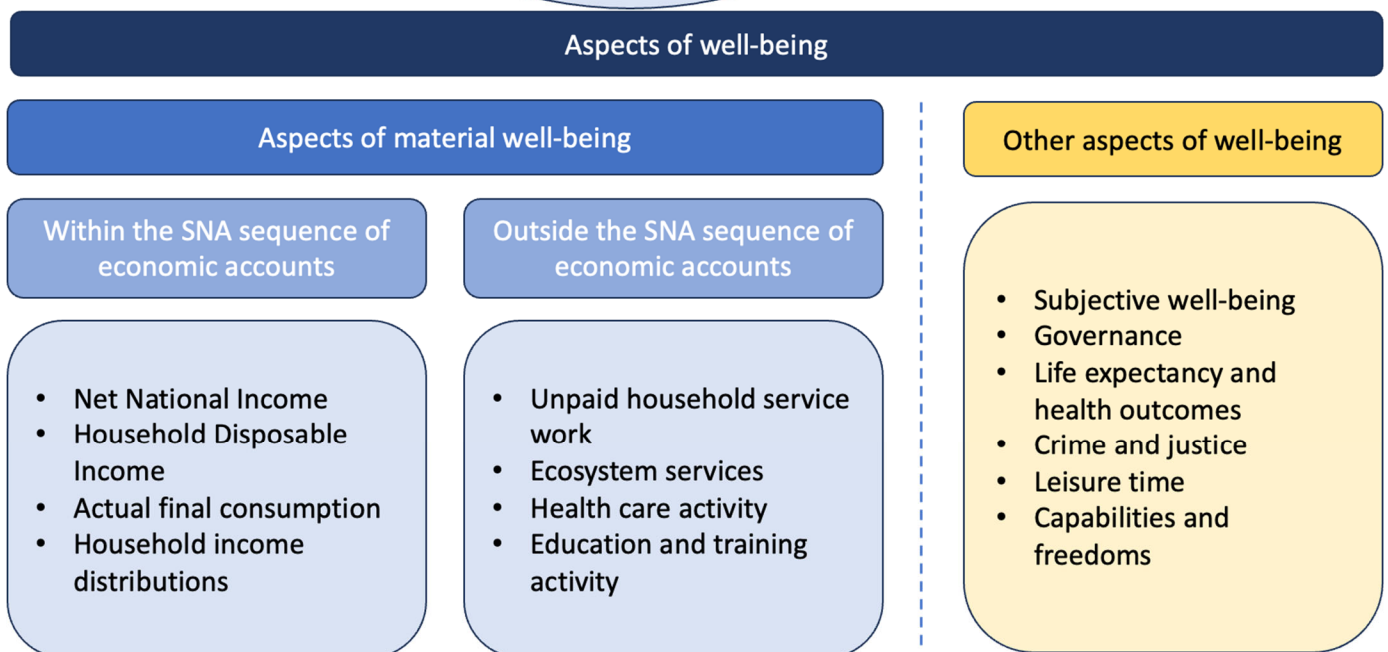

34.3.34.7 The depiction in Figure 34.1 reflects that the measurement of well-being described in this chapter does not provide a single overarching framework. Further, In effect, the aspects measures included in the first and second columns middle circle and described in this chapter are those that have been most developed in statistical and accounting terms. It is acknowledged that there are examples of statistical development for

---

<sup>1</sup> Household actual final consumption comprises household final consumption expenditure and social transfers in kind received by households  
(para ref)

aspects of well-being included in the third column -and the SNA framework remains open to the possibility of further extension and application of accounting approaches concerning other aspects of well-being in the future.

**Figure 34.1: Aspects of well-being**

~~34.4 For the measurement of material well-being. From a measurement perspective, well-being encompasses data about a number of elements, including health, education, income, employment, care, consumption and leisure, that collectively support assessment of the progress of people and communities and the extent to which the needs of current generations are satisfied.~~

~~34.5 The SNA sequence of economic accounts provides a range of relevant data to support reporting on well-being, particularly at the economy wide and institutional sector level. However, there are many aspects of well-being that are not quantified within the sequence of economic accounts. As introduced in Chapter 2, the 2025 SNA provides a broadened and enhanced framing for the measurement of well-being in which macro-economic measures, such as GDP, are complemented by other measures, while recognizing the relevance of accounting approaches in providing robust and comparable data to support policy development and assessment.~~

~~34.634.8 The broader and enhanced framing in Chapter 2 describes two primary avenues through which the SNA can contribute to the discussion of well-being. The first avenue recognizes that in addition to ,other than GDP, there is a very wide range of data and aggregate measures contained within the SNA's sequence of economic accounts that can be used as inputs to the analysis of well-being. These include measures of household disposable income, consumption, saving and net worth. TheFurther, it is possible to supplement the national level information presented in the sequence of economic accounts can also be supplemented with data on the distribution of these economic measures across groups of economic units. For example, measures of household income and wealth may be disaggregated by standard of living, type of household and other characteristics. This additional detail provides a richer body of data to support discussion of well-being.~~

~~34.9 The second avenue recognizes that a significant part of the development of frameworks and approaches to the measurement of material well-being has involved taking a more detailed focus on specific topics and, in a number of cases, extending and adapting the accounting rules and structures presented in the SNA to organize data on the various dimensions aspects of well-being. Examples of these accounting based approaches cover topics including unpaid household service work, health care expenditure, education and training, and environmental flows, including ecosystem services. These developments of these frameworks recognizes the potential of accounting-based approaches and the advantages of ensuring that data about the environmental and social dimensions can be readily connected to data from the SNA's sequence of economic accounts.~~

~~34.734.10 Chapter 2, Section B.4, provides a description of the links between accounting-based measures of well-being and measures of economic welfare. It explains that the position of the SNA is that while the change in GDP in volume (or real) terms is often taken as a measure of changes in material well-being or economic welfare, the SNA makes no claim that this is a preferred or appropriate measure. There are a number of conceptual matters and accounting conventions that are adopted in the SNA that are detailed in that section that are relevant to understanding the role of the SNA and extended accounts in supporting the analysis of economic welfare. These issues are not discussed further in this chapter.~~

~~Further, As introduced in Chapter 2 and noted elsewhere, the SNA has a focus on the measurement of outputs from economic activity rather than outcomes. As a result, the SNA does not organize data within the sequence of economic accounts that supports measurement of, for example, the quality of life of households. Further, as noted in Chapter 2, the measurement of well-being discussed here concerns objective rather than subjective measures.~~

~~34.11 In measuring these aspects of material well-being, the distinction between objective and subjective measurement is relevant. Objective measures of material well-being concern measures of various elements of people's lives such as income and consumption, health, knowledge and skills, use of time, and social connections. Subjective measures of well-being concern self-reported well-being, i.e., evaluations, both positive and negative, that people make about their lives and people's affective reactions to and reflections on their own experiences. This chapter focuses on the organization of data using accounting approaches to support objective measures of material well-being. The development of subjective measures of well-being is certainly relevant more broadly but is outside the scope of the SNAthis chapter.~~

~~34.834.12 It is common for the measurement of well-being to focus on the development of a set of indicators~~

and sometimes the indicators are aggregated to derive composite indicators. Where indicator-based approaches to measuring well-being are applied, the data organized using accounting-based approaches can readily support the organization of data for the derivation of indicators. This chapter does not discuss the content or derivation of composite indicators.

34.934.13 The discussion of objective measures of material well-being is presented across ~~five~~ four sections. In Section B, the measurement of material well-being in terms of income, consumption and wealth is considered commencing with an overview of the range of ~~macro-aggregate~~ economic measures of income, consumption and wealth available in the SNA sequence of economic accounts and introducing alternative measures of income and wealth that apply different concepts to those applied in the SNA.

34.1034.14 Section C discusses the distribution of income, consumption and wealth across households. To support this discussion, an overview of the scope and definition of households and household groups is provided. Detail on these and other aspects of measuring the household sector are elaborated in Chapter 32 on Households.

34.1134.15 In Section D, the measurement of well-being from the perspective of households as consumers and producers is considered, including the potential to extend the production boundary to incorporate flows that are not recorded in the sequence of accounts. From a consumption perspective, the discussion highlights the range of goods and services consumed by households that contribute to material well-being both within and beyond the SNA production boundary. From a production perspective, the discussion is framed in relation to the different forms of work that people undertake, including paid employment and unpaid household service work. By placing these various forms of work in a common context, a significant range of information can be organized including both labour input within the SNA production boundary and contributions of households beyond the production boundary.

34.16 In Sections ~~E and F~~, the discussion focuses on two specific aspects of well-being, namely health and education. The discussion of these aspects can be significantly supported by rich, accounting-based data sets. Measuring well-being associated with education is considered through ~~both accounting for human capital and~~ accounting for expenditures on education and training activity. Measuring well-being associated with health focuses on accounting for health care systems. Accounting for both of these areas can be directly linked to accounting for human capital which is discussed in Chapter 35.

34.1234.17 The discussion of accounting for health and education in Section E ~~here~~ does not cover the measurement of the outcomes arising from consumption, for example, the measurement of health outcomes using measures of the quality of life (see also Chapter 2, para xx). Further discussion on the measurement of the quality, and the impact on outcomes, of outputs supplied in activities such as health and education is included in Chapter 18 on the measurement of prices and volumes.

34.1334.18 The ~~c~~Chapter demonstrates the potential of accounting-based approaches to support the organization of relevant data, to build linkages between macro and micro perspectives on ~~economic-material~~ well-being (e.g., through the measures of household distributions of income and wealth and the measures of unpaid household service work) and to identify stronger connections between measurement in the economic and social dimensions of overall well-being. Nonetheless, as highlighted in Figure 34.1, the topics-aspects of material well-being discussed in this Chapter cover many, but by no means all, aspects relevant in the discussion of well-being. For example, there is no discussion of the measurement of health outcomes, trust and governance, civic engagement, crime, safety or accessibility, all of which will be relevant considerations.

34.1434.19 The descriptions of measurement and accounting in this chapter generally represent extensions beyond the SNA sequence of economic accounts. These extensions have been developed such that they can be implemented as individual accounts or used in a more combination with other accounts and data, ed fashion. The SNA provides conceptual guidance to facilitate international comparability and with the ambition aim that the SNA and its extensions it will be implemented followed by as many countries as possible. It, to facilitate international comparability, however, the SNA does not set expectations or provide direct recommendations on the accounts that should be compiled and it is recognized that it is not possible identify some extensions as “mandatory” in contrast to others that are “optional”. Not all countries will be able to provide the suggested degree of detail, but those countries that can implement the various accounts should follow these recommendations-descriptions provided in this chapter to support ensure comparability of data and methods. The choice of what to implement should take into consideration a country's economic,

social and environmental context, the current and future priority policy issues, and resources available for data collection and account compilation.

## B. Economy-wide Aggregate economic measures of well-being

34.1534.20 This section considers the measurement of well-being in terms of income, consumption and wealth in line with the SNA definitions of these concepts. There is a focus on economy-wide aggregate measures of income, consumption and wealth that can be derived from the sequence of economic accounts, and the discussion identifies a wide range of indicators other than the most common GDP per capita. The section also summarizes a number of alternative measures of income and wealth that apply different conceptual scopes.

### 1. Economy-wide Aggregate and institutional sector measures of income, consumption and wealth

34.1634.21 As ~~recognized in the introduction to this chapter, while not designed for this purpose,~~ the headline economic growth measure that is produced from the national accounts, GDP, is often used to represent societal progress or the economy-wide aggregate well-being of the population. However, GDP is one of a number of economy-wide aggregate and institutional sector measures of economic performance that are contained in the sequence of economic accounts. This section describes a range of relevant measures and related issues.

34.1734.22 GDP is a measure of the value added through production by resident economic units. While this focus encompasses a number of elements of income, in particular the returns to capital and labour used in the production process, it does not ~~incorporate reflect a other range of~~ items commonly considered in the discussion of income such as interest, dividends, taxes, ~~and~~ social insurance contributions and benefits, and social transfers in kind. The sequence of economic accounts has ~~a place~~ entries for all of these items and hence, depending on the income concept that is preferred, different measures of income can be derived.

34.23 The sequence of economic accounts is described fully in Chapter 3. In summary, the sequence represents a series of accounts each concerned with recording different parts of the economic activity involving all economic units. Each account is structured such that a balancing item is derived. By way of example, the first account in the sequence, the production account, records entries for output and intermediate consumption and the balancing item or position derived from this account is value added (i.e. output less intermediate consumption). The balancing item from one account serves as a starting point for the next account in the sequence. Table 34.1 provides a selection of stylized summary of economy-wide aggregate and institutional sector measures entries and balancing items from the sequence of economic accounts with balancing items highlighted in bold italics. connected using balancing items that “carry over” from one account to the next in the sequence. Balancing items are derived from aggregates within each account. For example, GDP is a balancing item from the production account derived by subtracting intermediate consumption from output. The sequence is described fully in Chapter 3.

34.24 For the purposes of assessing material well-being a number of different entries and balancing items are relevant. In relation to measuring measuring income, the recommended balancing items and associated aggregates entries are primary-earned income and adjusted disposable income adjusted for social transfers in kind. ~~For the measurement of~~ In relation to consumption, the recommended entries aggregates are final consumption expenditure and actual final consumption. ~~In relation to For the measurement of~~ wealth, and changes in wealth, the relevant balancing items are net lending, net worth and net financial worth. The connection between income and wealth is reflected in measures of net saving.

34.1834.25 Definitions of these ~~variables entries and balancing items~~ are provided in Chapter 3 and discussed in detail in chapters 7 – 14 on the sequence of economic accounts. Importantly, all of these measures are also established for individual institutional sectors, including corporations, general government and households. The range of different measures points to the relevance of compiling a full sequence of economic accounts and hence support a wide range of analysis across income, consumption and wealth, including the derivation

of multivariate indicators. Table 34.1 provides a stylized summary of economy-wide and institutional sector measures from the sequence of economic accounts.

**Table 34.1 ~~Selected aggregate Economy-wide~~ and institutional sector measures from the sequence of economic accounts**

		Institutional sectors					
		Non-financial corporations	Financial corporations	General government	Households	NPISH	Total economy
<b>Production account</b>							
	Output						
	Intermediate consumption						
	<b>Value added / GDP</b>						
<b>Distribution of income accounts</b>							
	Remuneration of employees						
	<b>Operating surplus / Mixed income</b>						
	Property income						
	<b>Earned income</b>						
	Social transfers in Kind (STIK)						
	Current transfers other than STIK						
	<b>Disposable income</b>						
	<b>Disposable income adjusted for STIK</b>						
	Final consumption expenditure						
	Actual final consumption						
	<b>Saving</b>						
<b>Capital account</b>							
	Gross capital formation						
	Depreciation						
	Depletion						
	<b>Net lending</b>						
<b>Financial account</b>							
	Net acquisition of financial assets						
	Net acquisition of liabilities						
	<b>Net lending</b>						
<b>Balance sheet</b>							
	Produced assets (excl. biological resources)						
	Natural resources						
	Non-produced assets (excl natural resources)						
	Financial assets						
	Liabilities						
	<b>Net financial worth</b>						
	<b>Net worth</b>						

~~34.19~~34.26 For many balancing items the preferred measurement is in net terms, i.e. after deducting the depreciation of fixed assets and the depletion of natural resources. Measurement in net terms provides the most appropriate measures of income and wealth for the purposes of assessing well-being since they take into consideration the decline in the value of capital over an accounting period that will influence the capacity of an economy to generate income and sustain well-being into the future. A longer discussion on the use of gross and net measures is presented in [Chapter 19].

~~34.20~~34.27 At a ~~national~~national economy-wide level, it is particularly evident that flows to and from the rest of the world need to be considered when measuring income and wealth. In measuring GDP, the connection to the rest of the world is reflected in the inclusion of exports and the deduction of imports. However, there are other flows that should be adjusted for to find an appropriate measure of national disposable income. This will include flows of property income (interest, dividends and other property income), flows of remittances and other transfers vis-à-vis the rest of the world.

~~34.21~~34.28 For the measurement of trends in material well-being over time and for comparisons across countries a number of adjustments to aggregate economic measures are appropriate. First, the effects of price changes must be removed. Thus, the focus is on volume measures of GDP and real measures of national income (elaborated in Chapter 18). Second, In addition, it is usual to express these measures in terms of the size of the population to which they relate, i.e. per capita. This can be particularly relevant in making comparisons across countries. International cSuch comparisons of material well-being will also be aided by making adjustments for (i) differences in purchasing power through the calculation and application of purchasing

power parities (PPPs) (elaborated in Chapter 18); (ii) differences in hours worked (elaborated in Chapter 16); and (iii) . It will also be relevant to address the impact of changes in the terms of trade (i.e. the difference between changes in export and import prices) on well-being (elaborated in Chapter 18). In summary, when a country's export prices rise more quickly than the prices of its imports (an improvement of the country's terms of trade), the country's citizens are better off and vice versa. The measurement of the terms of trade, including the measurement of trading gains and losses from changes in the terms of trade, is explained in chapter 18 on price and volume measures.

34.29 Bringing all of these considerations together enables a number of different, ~~yet SNA consistent,~~ measures to be derived reflecting the various different adjustments described in the previous paragraph. for (a) the costs of capital, (b) the effects of price changes, (c) the differences in population and (d) the variations in purchasing power. Examples of the range of measures start from GDP and GDP per capita and include net domestic product, net national income, real net national income, and real net national disposable income per capita. Each of these measures will provide insights into a country's level of material well-being and changes over time, primarily in terms of the total income available to support consumption and future investment. Section C (below) considers the distribution of income and wealth across population groups within a country.

34.22 ~~In addition, m~~Many of the aggregate measures of income and wealth described ~~in this section~~here are also compiled for institutional sectors within the sequence of economic accounts, including for non-financial and financial corporations, general government and households. These different aggregate and sectoral measures and the relationships between them are described in [Chapter 3].

34.30 Importantly, aAll of these calculations can be undertaken within the context of the sequence of economic accounts described in the SNA and the associated methods for making the adjustments just listed.

34.2334.31 Generally, ~~however,~~ the sequence of economic accounts is compiled only at the national level. In many countries there will also be interest in understanding variation within a country, for example across states, provinces or regions. For this purpose, regional (sub-national) accounts can be compiled noting that generally these accounts will focus on measures of production and value added rather than providing a sequence of accounts at regional scale, although more countries have started to compile regional estimates for households covering a broader range of accounts and indicators. The compilation of regional accounts is described in Chapter 20 ~~Elaborating the accounts.~~ For the purposes of assessing material well-being at the regional level, it is desirable to measure per capita household income and consumption ~~sincerecognizing that~~ measures of regional gross value added on a per capita basis will ~~often~~ be affected by variations in economic structure, prices and environmental context ~~that do not align with differences in well-being of residents in the regions.~~

## 2. Alternative measures of income and wealth

34.2434.32 To this point, tThe discussion of measures of income, consumption and wealth ~~in this section~~ has been based on the application of the concepts, definitions and measurement boundaries of the SNA. For some purposes, other measurement boundaries and definitions may be applied, often involving adjustments to the SNA definition and scope rather than being unconnected. For example, an alternative income concept ~~that~~ could be used that comes closer to what an individual household would normally consider as 'income', such as the income concept ~~as developed -used by the Canberra Group (UNECE, 2011).~~ This income ~~measure concept~~ states that "household income consists of all receipts whether monetary or in kind (goods and services) that are received by the household or individual members of the household at annual or more frequent intervals but excludes windfall gains and other such irregular and typically one-time receipts". From an SNA perspective, tThis alternative income concept is equal to adjusted disposable income as defined in the SNA minus non-life insurance benefits and winnings from lotteries. Further, the Canberra Group definition excludes specific national accounts related items such as imputed social contributions, investment income disbursements and the adjustment for FISIM.

34.2534.33 A broader income concept defines income as the maximum amount that can be consumed in a given period while keeping real wealth unchanged. This means that, in addition to income as defined in the SNA, the measure of income is adjusted for ~~includes~~ holding gains and losses related to the holding of non-financial and financial assets and liabilities. This measure ~~could-can~~ be derived using data from the SNA's

accumulation accounts by incorporating revaluations. However, for this purpose a distinction between realized and unrealized holding gains may be necessary.

<sup>34.26</sup><sup>34.34</sup> A broader wealth concept for households could also be measured to include social security pension entitlements as discussed in [Chapter xx]. These entitlements are not included within the asset boundary as defined in the SNA (para ref), but constitute an important resource for households when going into retirement. Data on these entitlements is captured in a supplementary table on social insurance pensions (table ref). While the government may have the ability to change the entitlements, by including these projected entitlements in household income analysis additional insights are provided about the resources that households expect to have available for their retirement and which may influence their current consumption decisions. The data can also support analysis of the impacts resulting from policy changes in relation to the aging society and explicitly accounting for the accrual of these entitlements will provide insight into the impact of re-distributional policies of government.

<sup>34.35</sup> Using these alternative measures of income and wealth ~~is~~are relevant in ~~measuring-assessing material~~ well-being ~~since~~as standard SNA measurements are designed to ensure aligned treatments across all sectors, and may not best reflect the perspectives of individual sectors or groups, particularly in relation to the behaviours and expectations of households.

## C. Accounting for the distribution of income, consumption and wealth across households

<sup>34.27</sup><sup>34.36</sup> ~~Economy-wide~~Aggregate economic measures are most useful for comparisons across countries but for the assessment of ~~material~~ well-being within a country a more targeted approach should be applied. In the first instance, it is appropriate to focus directly on measures of income, consumption and wealth for the household sector as a whole and then to consider the distribution of income, consumption and wealth across different households.

<sup>34.28</sup><sup>34.37</sup> Accounting for the distribution of household income, consumption and wealth supports the presentation of coherent and consistent data on these various entry points to the measurement of well-being. The accounting process facilitates the organization of data that are (i) coherent with macroeconomic aggregates, (ii) consistent across accounts within the household sector; ~~and~~ (iii) comparable over time and across countries; and (iv) consistent with the accounts of the other sectors due to adherence to quadruple entry accounting principles. To these ends, it requires that the compilation of distributional accounts takes into consideration the joint relationships between income, consumption and wealth. This in turn supports the computation of multivariate indicators (such as consumption-to-income, debt-to-income or wealth-to-income ratios) for the various breakdowns of the household sector.

<sup>34.29</sup><sup>34.38</sup> The discussion of the distribution of income, consumption and wealth has been of increasing interest in many policy areas and there is substantive measurement experience and guidance available to support work in this area. This section summarizes key aspects of the definition and scope of households in the SNA and lists the different groupings of households that will be relevant in distributional measurement and analysis. The section then ~~introduces the measurement of household income, consumption and wealth and~~ summarizes key points in measuring the distribution of household income, consumption and wealth.

<sup>34.39</sup> Although distributional accounts use households as the unit of analysis, and while individuals are not distinct institutional units in the SNA, for a number of topics in the measurement of well-being, the collection and organization of data by type of individual is appropriate and necessary. For example, the measurement of labour input and human capital is associated with the skills, experience and earnings of individuals; the measurement of time use is undertaken by recording the activities of individuals, and in the assessment of health and education it is individuals who benefit in the first instance. Since the total number of individuals in the resident population must align with the total number of individuals within households, in aggregate there is no conceptual difference in scope whether individuals or households as the unit of analysis. The choice of unit of analysis should therefore be made on the basis of relevance and data availability.

<sup>34.30</sup><sup>34.40</sup> A more detailed elaboration of households and household distributions is presented in Chapter 32 on Households. Chapter 32 provides an introduction to a number of measurement considerations including

the potential, via a national accounting framework, to integrate and reconcile data about household income, consumption and wealth from both macro and micro based data sources. Generally speaking, measures of household distributions will require micro data as a fundamental input, for example from household surveys or administrative data sources (e.g. taxation statistics). However, there are often differences in measurement approach at the micro level that require adjustment to allow integration with macro data from the national accounts. A detailed explanation of compilation and reconciliation issues is described in the Handbook on Compiling Distributional Results on Household Income, Consumption and Saving (OECD, et al, forthcoming).

## 1. The scope of households

34.3134.41 For consistent measurement and analysis, it is necessary to define the set of households within the scope of measurement for distributional accounting and analysis. The definition, measurement scope and associated considerations concerning households is articulated in Chapter 6 and Chapter 32 and the same definition and treatments are applied in this chapter. The key aspects are summarized below.

34.3234.42 Chapter 6 recognizes two main types of units that may qualify as institutional units, namely persons or groups of persons in the form of households, and legal or social entities. In the SNA, ***a household is a group of persons who share the same living accommodation, who pool some, or all, of their income and wealth and who consume certain types of goods and services collectively, mainly housing and food.***

34.3334.43 In distributional accounts, the individual members of multi-person households are not treated as separate institutional units, i.e. the unit of analysis is a household. This treatment recognizes that many assets are owned, or liabilities incurred, jointly by two or more members of the same household, while some or all of the income received by individual members of the same household may be pooled for the benefit of all members. Moreover, many expenditure decisions, especially those relating to the consumption of food, or housing, may be made collectively for the household as a whole. For these reasons, the household as a whole rather than the individual persons in it are treated as the institutional unit.

34.3434.44 A household unit may coincide with the concept of a family, but members of the same household do not necessarily have to belong to the same family so long as there is some sharing of resources and consumption. Households may be of any size and take a wide variety of different forms in different societies or cultures depending on tradition, religion, education, climate, geography, history and other socio-economic factors. The definition of a household that is adopted by survey statisticians familiar with the socio-economic conditions within a given country is likely to approximate closely to the concept of a household as defined in the SNA, although survey statisticians may add more precise, or operational, criteria within a particular country.

34.3534.45 The definition of families can vary in different societies and cultures but it may be a useful unit of analysis in some contexts. In many instances, families will encompass multiple household units as defined in the SNA. Thus, it may be the case that in the collection and analysis of time-use survey data, the scope of unpaid household service work encompasses services provided to people considered family members but who are outside the household unit defined by the SNA. This is discussed further in Section D.3.

34.3634.46 As described in Chapter 5, the residence of individual persons is determined by the location (principal residence) of the household of which they form part and not by their place of work. All members of the same household have the same residence as the household itself, even though they may cross borders to work or otherwise spend periods of time abroad. If they work and reside abroad for sufficient time such that they acquire a centre of economic interest abroad, they cease to be members of their original households.

34.3734.47 As well as private households, there are units described as institutional households that comprise groups of persons residing in hospitals, retirement homes, convents, prisons, etc. for long periods of time, usually interpreted as one year. These people are treated as belonging to a single institutional household when they have little or no autonomy of action or decision in economic matters. On the other hand, people who enter hospitals, clinics, convalescent homes, religious retreats, or similar institutions for short periods, who attend residential schools, colleges or universities, or who serve short prison sentences should be treated as members of the private households to which they normally belong.

34.3834.48 Conceptually, the measurement of economic well-being of households for a country should encompass all resident households including institutional households. In practice, the collection of data on

institutional households may be difficult but estimates can be made using household survey data, census data, administrative data, counter-party data or other methods to ensure as complete a picture as possible is developed of the household sector.

~~34.39~~34.49 While the household constitutes the unit of analysis, households may differ in size and composition, and as a consequence they will have different consumption needs. Thus, for some aspects in the measurement of well-being, such as in the analysis of data on income and consumption at the household level, it is recommended to focus on 'equivalized' results, using equivalence scales that take into account differences in size and composition of households, to arrive at comparable results across households, recalculating results according to the number of consumption units in each household. The use of equivalence scales for wealth is also relevant but since wealth may not benefit all current household members, (i.e. it may provide benefits in the future) there is less consensus on which equivalence scales are appropriate and different types of scales may be needed compared to those used for income and consumption. Further discussion of household equivalence is presented in Chapter 32 on Households.

~~34.40~~34.50 More generally, there are many different types of households such that a focus on the well-being of all households "on average" presents a far more limited description of current and past trends in (material) well-being than data presented according to different typologies of households. A range of typologies may be used depending on the analytical question and the availability of data. The main criteria for grouping households ~~Primary types of households~~ are:

- ~~Ranking households into relative e~~Current income or wealth groups, for example, quintiles, deciles, percentiles or more granular groups (e.g. top 0.1% of income) on the basis of equivalized disposable income or net worth.
- ~~Ranking on the basis of r~~Regular income taking into account ~~life cycle~~ (stage of life) effects and business cycle effects, into groups such as quintiles, deciles, etc.
- ~~Grouping households according to their m~~Main source (i.e. highest share) of income; e.g. according to wages and salaries, gross mixed income from household unincorporated enterprises, net property income receivable and net current transfers receivable (potentially further separating pension benefits receivable).
- ~~Grouping according to the n~~Number and age of members of the household. For example, the following eight household compositions could be used: single less than 65 years old; single 65 and older; single with children living at home; two adults less than 65 without children living at home; two adults at least one 65 or older without children living at home; two adults with less than 3 children living at home; two adults with at least 3 children living at home; and other.
- ~~Grouping according to the e~~Characteristics of a reference person within the household (e.g. according to age, sex, labour market status, educational attainment, disability status).<sup>2</sup>
- ~~Grouping by g~~Geographic region and degree of urbanization (e.g. rural, remote, urban).
- ~~Grouping by h~~Housing status (e.g. rental, owner-occupied).

~~34.41~~34.51 In presenting data according to these household types, it is relevant to ~~also record~~ complementary information on the relevant socio-demographic ~~characteristics of information about~~ all individuals within members of the households (e.g., their age, sex, income, employment status, educational attainment). This information supports a richer understanding of the household sector given that households are generally composed of a variety of individuals with different characteristics. As a specific example, grouping households ~~types~~ based on the characteristics of a reference person may lead to results that are not always ~~be~~ representative of the full population since as the measurement reflects only the socio-demographic characteristics of the reference person. Thus, when considering analysis by sex, the distributions will not reflect differences between men and women in general, but rather will reflect differences between households

<sup>2</sup> The use of a reference person approach to household groupings should be undertaken with care as the set of reference persons may not be representative of the wider population. See para ~~34.51~~40 for additional comment.

where a man is the reference person and those where a woman is the reference person.<sup>3</sup>

~~34.42 Although distributional accounts use households as the unit of analysis, and while individuals are not distinct institutional units in the SNA, for a number of topics in the measurement of well-being, the collection and organization of data by type of individual is appropriate and necessary. For example, the measurement of labour input and human capital is associated with the skills, experience and earnings of individuals; the measurement of time use is undertaken by recording the activities of individuals, and in the assessment of health and education it is individuals who benefit in the first instance. Since the total number of individuals in the resident population must align with the total number of individuals within households, in aggregate there is no conceptual difference in scope whether individuals or households as the unit of analysis. The choice of unit of analysis should therefore be made on the basis of relevance and data availability.~~

## 2. **Compiling ~~distributional~~ accounts for the distribution of household income, consumption and wealths**

~~34.43~~34.52 The compilation of accounts showing the distribution of household income, consumption and wealth ~~distributional results~~ entails breaking down results for various accounts of the household sector as defined within the SNA, into more granular subsectors consisting of specific groups of households. Ideally, this should be done for the whole sequence of interconnected household sector accounts representing different types of economic activity occurring within a period of time, including balance sheets that record stocks of assets and liabilities held by the household sector at the start and end of that period. Table 34.2 provides selected measures a stylized summary of the potential from the sequence of economic accounts for the household sector distributed range of measures using income deciles to define the types groups of households as recommended in Chapter 5. This focus for measurement leads to a consistent and comprehensive description of different groups of households across the various accounts.

**Table 34.2. Selected measures for the household sector from the sequence of economic accounts by household type income decile**

---

<sup>3</sup> Sex is recognized as a core demographic variable about which data are regularly collected in censuses and household surveys. This variable may also be referred to as gender and sometimes these terms are used interchangeably. In data collection, some countries allow for respondents to provide a more nuanced expression of their identity beyond traditional binary response options. [For more resources see https://data.unwomen.org/resources.](https://data.unwomen.org/resources)

		Household type (income decile)										
		1st	2nd	3rd	4th	5th	6th	7th	8th	9th	10th	Total households
<b>Production account</b>												
	Output											
	Intermediate consumption											
	<b>Value added / GDP</b>											
<b>Distribution of income accounts</b>												
	Remuneration of employees											
	<b>Operating surplus / Mixed income</b>											
	Property income											
	<b>Earned income</b>											
	Social transfers in Kind (STIK)											
	Current transfers other than STIK											
	<b>Disposable income</b>											
	<b>Disposable income adjusted for STIK</b>											
	Final consumption expenditure											
	Actual final consumption											
	<b>Saving</b>											
<b>Capital account</b>												
	Gross capital formation											
	Depreciation											
	Depletion											
	<b>Net lending</b>											
<b>Financial account</b>												
	Net acquisition of financial assets											
	Net acquisition of liabilities											
	<b>Net lending</b>											
<b>Balance sheet</b>												
	Produced assets (excl. biological resources)											
	Natural resources											
	Non-produced assets (excl natural resources)											
	Financial assets											
	Liabilities											
	<b>Net financial worth</b>											
	<b>Net worth</b>											

34.4434.53 The sequence of economic accounts presents accounting entries that are ~~is~~ connected through balancing items. with ~~The~~ full sequence is described in Chapter 3. For distributional analysis, it is recommended that focus is placed on the following balancing items ~~entries and balancing items~~ from the accounts for the household sector ~~be the focus~~:

- For analysing the distribution of household income, the relevant balancing items are ‘primary ~~earned~~ income’, ‘disposable income’ and ‘~~adjusted~~ disposable income adjusted for social transfers in kind’.
- For analysing the distribution of household consumption, the relevant balancing items ~~entries~~ are ‘final consumption expenditure’ and ‘actual final consumption’.
- For analysing the distribution of household wealth, the relevant balancing items are ‘net worth’ and ‘net financial worth’.

34.4534.54 While the starting point is the household sector as defined in the SNA, with the household as the unit of observation, the focus for analysis should be on equivalized results, i.e. using equivalence scales to arrive at comparable results accounting for differences in household size and composition. Further, results for institutional households should be presented separately because of the large heterogeneity of this group and their different behaviours compared to private households. It is recommended to present results for the total of institutional households, accompanied by information on the total number of persons and consumption units included in institutional households.

34.4634.55 As described above, there are different groupings of households that may be relevant for the assessment of well-being and hence of interest in distributional analysis. Depending on analytical interest and data availability, all of the groupings proposed above may be considered. To support international

comparability, it is recommended that compilers provide breakdowns by standard of living based on (current) disposable income and based on wealth, showing income and wealth decile groups, a median and, if possible, results for the top 5% and the top 1%. Alternative breakdowns by main source of income, household type, housing status and by age of the reference person are also encouraged.

~~34.47~~34.56 There is a range of challenges in the compilation of distributional accounts. These include the measurement of inter-household flows and stocks, including inter-generational transfers; determining the equivalence of households, including over time; the allocation to individual households of items for which household level (micro) data are lacking (e.g. measures of the non-observed economy, disbursements of investment income and FISIM); the challenge of linking data across different data sources using statistical matching techniques; breaking down changes in wealth into underlying flows; and compiling price indices for different household groups. These and other measurement challenges are discussed further in Chapter 32.

~~34.48~~34.57 The well-being of different household groups will also be affected by different levels of ownership of consumer durables. ~~Although it is not recommended to remove the expenditure on consumer durables from the final consumption measure in the SNA, f~~For the purpose of compiling distributional results, it is recommended that countries show separate estimates of expenditure on consumer durables and associated measures of depreciation as memorandum items. ~~This is particularly relevant in supporting the analysis, particularly as they may significantly affect measures of household saving. Further, e~~Estimates of the value of the stock of consumer durables will ~~also~~ be relevant in the analysis of household wealth. The treatment and measurement of consumer durables is discussed in Chapter 10.

34.58 The focus of household distributions in this section has been on entries concerning income, consumption and wealth within the scope of the sequence of economic accounts. However, distributional analysis should not be confined to these ~~variables-entries~~ and analysis of many of the topics discussed in the following sections, including unpaid household service work, health care, and education and training, will be substantially enhanced through the provision of household distributions for relevant variables.

~~34.49~~34.59 In addition, measures of the distribution of household income and consumption as described above may be extended to incorporate data on income and consumption beyond the SNA production boundary, in particular concerning unpaid household service work. It is likely that flows of unpaid work will vary considerably across household types and thus change the relative distributions of income and consumption, for example across income deciles.

## D. Measures of household consumption and production

~~34.60~~ This section describes how the measurement of the economic well-being of households can be supported by measuring household consumption and production, including through the extension of measures of consumption and production beyond the SNA production boundary. The section commences with a discussion on household consumption since this is a common entry point to the discussion of household well-being, i.e. material well-being is commonly considered in terms of the set of goods, services and other benefits enjoyed by people.

~~34.50~~34.61 The discussion of household consumption here recognizes that a focus only on those goods and services within the scope of the SNA production boundary is ~~necessary but~~ not sufficient for the assessment of material well-being. It is also noted that there will be a range of complementary indicators, for example, concerning population and housing density, housing and rental costs, and access to transport facilities, that will be relevant in assessing material well-being. While some of the data to underpin the derivation of such indicators can be derived from accounting based data sets, this section does not document the indicators that might be selected for assessment of well-being.

34.62 From a household production perspective, the measurement of well-being requires bringing into view a broader range of activities that people undertake including unpaid household service work. To provide a statistical basis for the measurement of these activities, the section uses the forms of work framework. By placing these forms of work in context, a significant range of information can be organized including both labour input within the SNA production boundary and contributions of households beyond the production boundary, for example in volunteering, and most broadly to the wider measurement of time-use. Connections can then be made to data concerning unemployment and working conditions, thus supporting the integrated

assessment of economic and social issues.

34.63 Note that in the SNA there is no equivalence between total household consumption and total household contribution to production. Thus, measures of household consumption will include goods and services that are produced by other economic units including goods and services imported from the rest of the world. As well, the contribution of households to production will extend beyond the operation of their own households and include labour inputs to the production of goods and services used by other economic units.

34.51—

## 1. Sources of household consumption

34.5234.64 Within the SNA ~~sequence of economic accounts~~~~production boundary~~, household expenditures on ~~relevant~~ goods and services include consumption of food, clothing, energy, water, housing, transport, recreation, education and health. Expenditure on these items is included in the measure of **household final consumption expenditure**. In aggregate, and in real, per capita terms, data about the level of and changes in household final consumption expenditure ~~, i.e. household consumption of goods and services within the SNA production boundary,~~ is of considerable relevance in the assessment of ~~economic-material~~ well-being and in particular for comparisons across countries. The relevant considerations for the measurement of expenditure by type of good and service ~~— classified using COICOP -~~ are detailed in Chapter 10.

34.65 ~~The measurement of household final consumption expenditure~~ ~~The SNA production boundary~~ explicitly includes ~~the production of~~ goods produced by households that are subsequently consumed by those same households, i.e. household output for own final use [Chapter 7.xx]. In the context of assessing material well-being within and across countries, the level of this consumption is of significant policy interest, in particular concerning subsistence production and consumption of food, water and fuel. Subsistence producers, which may include indigenous and First Nations peoples, constitute an important group in relation to own-use production of goods. Subsistence producers are defined as all those who produce and/or process for storage agricultural, fishing, hunting and gathering products that contribute to the livelihood of the household or family.

~~34.53~~ ~~Data on the number and types of households that undertake own-use production and consumption of goods may provide important insights into the distribution of income and consumption. Further, information on the quantity of production (e.g. tonnes) classified by type of economic activity (e.g. agriculture) and product (e.g. rice) will be relevant in both understanding the economic well-being of households and supporting the derivation of good measures of the monetary value of this activity for inclusion in wider measures of economic activity for a country. Additional information on the nutritional value (e.g., kJ) of food consumed through subsistence production may also be of relevance in certain analysis.~~

34.5434.66 Another specific area of policy interest is the own-use production and consumption of energy by households particularly as it concerns the wider response to the challenges of mitigating the effects of climate change, but also in the context of volatility in the cost of energy. Depending on the economic context, own-use production of energy extends from the collection of firewood or other biological resources for combustion, to the installation of infrastructure to capture energy from renewable sources, for example, solar panels and windmills.

34.67 The sequence of economic accounts complements the measures of household final consumption expenditure with measures of household actual final consumption. Measures of actual final consumption are of particular relevance in international comparisons since they allow for variations in the extent to which household consumption is paid for by general government and NPISHs via their provision of non-market goods and services to households and their procurement of market goods and services on behalf of households. Important examples include government expenditure on health and education. In the sequence of economic accounts, there are corresponding entries for social transfers in kind to ensure that the relevant~~financial~~ transactions balance appropriately. Chapter 10 explains these issues in detail.

34.68 The analysis of economic well-being is also supported by the organization of data on the collective consumption of government which, on the whole, corresponds to the supply of public goods. For example, data on levels of government expenditure on health care infrastructure, education and training facilities,

public infrastructure for transport and roads, national parks and sporting facilities provide important insights into the level of well-being of a community. Often, interest is in measures commonly associated with public infrastructure and the assessment of the trends in gross fixed capital formation on these items is relevant.

34.55—To support understanding the relationship between employment and own-use production of goods, it is also beneficial to organize data on the number of people and their hours of work engaged in these activities. For example, data on time spent collecting water and firewood.

34.5634.69—For all components of household consumption, measures of the relative shares of expenditure on different goods and services, for example, the share spent on food or energy, are of high interest, particularly in situations where relative price movements for different products are diverging. Consequently, measurement of consumption expenditure in volume terms is also important for analysis. Relevant measurement advice concerning prices and volumes is described in Chapter 18.

34.57—The preceding discussion focused on consumption within the sequence of economic accounts. There are a number of types of household consumption outside this scope that are relevant in assessing material well-being. First, it is noted that In addition to the derivation of price and volume indexes, complementary tables presenting non-monetary data can be compiled for selected goods and services. For example, estimates of consumption for various food products in terms of weight or nutritional content can be derived. The FAO food balance sheets provide an indication of what is possible in this direction. Similarly, estimates of energy consumption in joules and transport activity in kilometres can support richer analysis of expenditure data. Data on consumption in physical terms can be linked or taken from physical supply and use tables compiled following the SEEA Central Framework. A more complete mapping of physical flows for selected products can directly support analysis of solid waste, recycling and reuse as part of understanding the circular economy.

34.5834.70—The sequence of economic accounts treats household purchases of **consumer durables** such as cars and washing machines, as consumption expenditure. As recognized in Chapter 10, since this expenditure concerns items which provide services to households over an extended period of time, it is recommended that the expenditure ~~on these items~~ be separately identified and recorded as memorandum items. Analysis of ~~this expenditure on consumer durables~~ relative to total household consumption expenditure gives important insights to economic-material well-being, especially for different household types.

34.59—The sequence of economic accounts complements the measures of household final consumption expenditure with measures of **household actual final consumption**. Measures of actual consumption are of particular relevance in international comparisons since they allow for variations in the extent to which household consumption is paid for by general government and NPISH via their provision of non-market goods and services to households and their procurement of market goods and services on behalf of households. Important examples include government expenditure on health and education. In the sequence of economic accounts, there are corresponding entries for social transfers in kind to ensure that the financial transactions balance appropriately. Chapter 10 explains these issues in detail.

34.60—The analysis of economic well-being is also supported by the organization of data on the collective consumption of government which, on the whole, corresponds to the supply of public goods. For example, data on levels of government expenditure on health care infrastructure, education and training facilities, public transport and roads, national parks and sporting facilities provide important insights into the level of well-being of a community. Often, interest is in measures commonly associated with public infrastructure and the assessment of the trends in gross fixed capital formation on these items is relevant.

34.6134.71—To support measurement of well-being, the measurement of household consumption can be extended to include benefits obtained by households from production that ~~is are~~ outside the SNA production boundary. Of high importance are the benefits arising from **unpaid household service work**. The measurement of this activity is described in detailed in section D.3. While this activity is outside the SNA production boundary, it is within the general production boundary described in Chapter 7. The general production ~~boundary is a broader concept than the SNA production boundary that~~ includes all economic production, i.e. activity carried out under the control and responsibility of institutional units that use inputs of labour, capital, and goods and services to produce outputs of goods and services.

34.6234.72—Outside the general production boundary but of significance ~~ce t-relevance~~ for assessing well-being are **non-productive activities undertaken by individuals**. These activities include basic human activities such

as eating, drinking, sleeping, leisure, exercising, etc. They are considered non-productive since it is not possible for one person to employ another person to perform the activity for them. Commonly, this is referred to as the “third party criterion”. While these activities may be non-productive in an economic sense, the benefits they generate clearly contribute to well-being and in particular to health outcomes. From an accounting perspective there is no monetary value that is placed on the benefits arising from these activities. However, the organization of data on the time spent undertaking these activities, particularly sleeping, leisure and exercise, may be of particular interest. A complete accounting of time-use, as discussed in section C.4, is the appropriate approach for organizing the relevant information.

**34.73** Also outside of the general production boundary, households benefit from a wide range of **ecosystem services**. Following the SEEA Ecosystem Accounting (SEEA EA), *ecosystem services are the contributions of ecosystems to the benefits that are used in economic and other human activity*. Examples of ecosystem services of benefit to households include provisioning services embodied in crops, livestock and timber products that are ultimately consumed by households; cultural services such as those related to recreation and amenity values and amenity; and regulating and maintenance services such as air filtration, water regulation and purification, flood mitigation, soil erosion control, noise attenuation and global climate regulation.

~~34.63~~ Generally, the flows of provisioning and cultural services are more readily observed in connection with the day-to-day activity of households and commonly the monetary value of these services is embodied in the values of goods and services ultimately purchased by households such as food, clothing and recreation services. For regulating services, the situation is different and most of these services reflect ongoing natural processes and ecological functions that households are largely unaware of. Indeed, in many cases they reflect a form of collective consumption following the definition in the SNA.

~~34.64~~**34.74** ~~The organization of data on flows of ecosystem services, and other data related to ecosystems, for example on water quality and the condition of forests, can be undertaken using the accounting framework described in the SEEA EA. The SEEA EA is an international statistical standard for recording data about ecosystems in non-monetary terms. It also provides internationally recognized statistical principles and recommendations for their measurement in monetary terms, recognizing the general challenges of valuation for non-market services. In different locations and under different economic structures, the dependence on and connection to ecosystems exhibited by households will vary. It will also vary by type of household. Thus, data about the flows of ecosystem services, including recording which population groups use and benefit from these services,~~ will be relevant in both understanding the full breadth of household consumption and in understanding the sustainability of that consumption in relation to the extent and condition of the underlying natural capital. This latter topic is discussed further in Chapter 35.

~~34.65~~**34.75** Beyond the ecosystem services recorded in the SEEA EA, the environment provides benefits related to the more general appreciation that people hold for ecosystems and species. In environmental economics, these benefits are commonly referred to as non-use values. While methods to measure non-use values are available, for example, using choice experiments and contingent valuations, these valuations are considered inconsistent with the ~~valuation~~ concept of exchange values applied in the SNA and SEEA. As part of its description of applications and extensions of ecosystem accounting, SEEA EA Chapter 12 outlines ways in which data about non-use values may be placed in context with accounting-based data to provide wider measures of consumption and well-being. ~~support discussion of multiple value perspectives.~~

~~34.66~~**34.76** Table 34.3 provides a summary structure for recording selected data on ~~the sources of~~ household consumption by type of household differentiating consumption by source of consumption.

**Table 34.3: Sources of Selected data on household consumption by type of household by source of consumption**

		Household type (income decile)										
		1st	2nd	3rd	4th	5th	6th	7th	8th	9th	10th	Total households
Sources of household consumption												
Household final consumption expenditure by COICOP												
Social transfers in kind												
Household actual final consumption												
Unpaid household service work by type of service												
Ecosystem services												

34.77 In addition to data in monetary terms, a range of non-monetary data can be used to support analysis of material well-being, recognizing that these data cannot fully inform the assessment of the trade-offs in consumption made by households over time. As an example of non-monetary data, data on the number and types of households that undertake own-use production and consumption of goods may provide important insights into the distribution of income and consumption. For example, data on time spent collecting water and firewood. Also, in addition to the derivation of price and volume indexes for all goods and services, complementary tables presenting non-monetary data can be compiled for selected goods and services following an accounting based approach, such as reflected in the physical flow accounts of the SEEA Central Framework. For example, estimates of consumption for various food products in terms of weight or nutritional content can be derived. The Food and Agriculture Organization of the UN (FAO) food balance sheets provide an indication of what is possible in this direction. Similarly, estimates of energy consumption in joules and transport activity in kilometres can support richer analysis of household expenditure data. A more complete mapping of physical flows for selected products can directly support analysis of solid waste, recycling and reuse as part of understanding the circular economy.

~~To support understanding the relationship between employment and own use production of goods, it is also beneficial to organize data on the number of people and their hours of work engaged in these activities. For example, data on time spent collecting water and firewood.~~

## 2. Forms of work

34.78 ~~While a~~ focus on household consumption and the range of benefits that people enjoy is a relevant entry point to the measurement of material well-being. ~~A complementary, a~~ focus on the activities that people undertake, both economic and non-economic, also provides important information on people's well-being. This section discusses the various forms of work that individuals engage in while section D.4 introduces approaches to accounting for all uses of time, including leisure.

34.6734.79 The appropriate standard for recording data on people's economic activities, defined as those activities within the general production boundary (see Chapter 7), is the international statistical standard definition of employment from the 19<sup>th</sup> ICLS [Resolution concerning statistics of work, employment and labour underutilization](#) adopted in 2013<sup>4</sup>. This Resolution provides the standard definition of the concept of work and describes the forms of work framework in which employment work is the key reference concept. The Resolution establishes that the concept of work "comprises any activity performed by persons of any sex and age to produce goods or to provide services for use by others or for own use."

34.6834.80 The Resolution identifies five forms of work which are distinguished by the intended destination of

<sup>4</sup> [https://www.ilo.org/wcmsp5/groups/public/---dgreports/---stat/documents/normativeinstrument/wcms\\_230304.pdf](https://www.ilo.org/wcmsp5/groups/public/---dgreports/---stat/documents/normativeinstrument/wcms_230304.pdf)

the production (for own final use; or for use by others, i.e., other economic units) and the nature of the transaction (i.e., monetary or non-monetary transactions, and transfers):

- a. *own-use production work* comprising production of goods and services for own final use;
- b. *employment work* comprising work performed for others in exchange for pay or profit;
- c. *unpaid trainee work comprising work* performed for others without pay to acquire workplace experience or skills;
- d. *volunteer work* comprising non-compulsory work performed for others without pay; and
- e. *other work activities*.<sup>5</sup>

~~34.69~~34.81 From the perspective of the activities within the SNA production boundary, the most important form of work is employment with the most significant portion of this component relating to the contribution of employees. From the perspective of household well-being, employment related data are of high relevance including measures of remuneration of employees, number of employees, and hours worked. Such data can be used to derive indicators such as mean and median earnings. These employment related data also underpin accounting for human capital as described in Section E. The organization of these data in an accounting context is described in Chapter 16 on Labour tables. In addition, organizing these data by type of household following the groupings listed in Section C.1 and in terms of characteristics of individuals such as age and sex is relevant. Of particular note is the measurement of the distribution of income for which the distribution of remuneration of employees will be a core element (see Chapter 32 on Households).

~~34.70~~34.82 Chapter 16 on Labour tables provides a richer description of the relationships between these five forms of work, the SNA production boundary, as applied in the sequence of economic accounts, and the general production boundary. The core message is that while employment as a form of work is important, there is also a range of other ways in which people contribute to activities within the general production boundary. Measurement of these non-employment contributions provides important insights into household well-being.

~~34.71~~34.83 In terms of non-employment contributions, of most significance in the measurement of well-being is the activity associated with unpaid household service work. In the forms of work framing, unpaid household service work includes both services produced for own-final use and services produced for other economic units through volunteer work. The measurement of unpaid household service work is discussed in detail in the following section.

~~34.72~~34.84 A related perspective on the forms of work listed above concerns the distinction between the formal and informal economy. As defined in Chapter 39, the informal economy refers to the productive activities carried out by persons or economic units that are not covered by formal arrangements established by regulations and laws and includes all informal productive activities carried within the general production boundary. The overarching concept of the informal economy is defined as constituting all informal productive activities carried out by workers or economic units within the general production boundary. In the same vein, the measurement of the non-observed and illegal economy is relevant in assessment of household well-being in many countries. Chapter 39 provides a description of accounting approaches to the measurement of the informal economy. The measurement considerations outlined in Chapter 39 can be linked to the discussion in this chapter on well-being recognizing that the key connecting concepts are the SNA production boundary and the general production boundary.

~~34.73~~34.85 Table 34.4 provides a summary structure for recording information on the activity of individuals across the different forms of work.

---

<sup>5</sup> These “other work activities” include such activities as unpaid community service and unpaid work by prisoners, when ordered by a court or similar authority, and unpaid military or alternative civilian service, which may be treated as a distinct form of work for measurement (such as compulsory work performed without pay for others) (ICLS Resolution, page 3).

**Table 34.4: Forms of work by individual characteristics**

		Forms of work						of which: Unpaid household service work	
		Own-use production work		Employment work	Unpaid trainee work	Volunteer work	Other work		Total
			of which: Unpaid household service work						Own-use production work + Volunteer work
		Number of people / Hours							
Total									
By individual characteristic									
	Age

	Educational attainment								

### 3. Unpaid household service work

34.74<sup>34.86</sup> Chapter 7 recognizes that there are many activities undertaken by households that satisfy the general production boundary involving the use of labour and capital for the production of goods and services. However, the SNA production boundary applied in practice only includes those household activities that produce goods (as discussed above) and the activities of the production for own final use of housing services by owner-occupiers and the production of domestic and personal services by employing paid domestic staff. Chapter 7 [para xx-xx] provides a full explanation of this treatment. The exclusion of unpaid household service work from the SNA production boundary is seen as a significant limitation in using GDP as a measure of well-being since it omits a significant volume of production and consumption undertaken by households that relates directly to the health, education and general well-being of people. Given this limitation, accounting for unpaid household service work provides important insights into economic well-being and a range of data can be organized following accounting principles to support extended analysis.

34.75—In making the connection to well-being, unpaid household service work is thought of as an input that, together with market goods and services, is transformed into household goods and services (i.e. caring, cooking, cleaning, maintenance) that are consumed by household members and benefit individual well-being. This process operates through intermediate stages involving intra-household production, cooperation and distribution activities. The relationship between inputs (purchased goods and services and unpaid work) and well-being is not direct and immediate, and the household plays an important role within this process.

34.87 The progression from the initial stage (market goods and services) to the final stage of this process (individual well-being) creates added value in society, so that individual and social well-being is greater than the value of the available goods purchased on the market.

34.88 To completely reflect the activity of unpaid household service work within a sequence of economic accounts, there are a number of implications for current entries in addition to recording additional output by households. Of particular note is that by extending the production boundary to include this activity, a range of expenditures treated as household final consumption expenditure, for example food, would become intermediate consumption as inputs to the unpaid household service work. Also, expenditure on consumer durables, such as refrigerators, that are also treated as household final consumption expenditure, would become gross fixed capital formation as produced assets providing capital services as inputs to the unpaid household service work. A description of the range of adjustments that would be required to the current SNA sequence of economic accounts is provided in the UNECE Guide on Valuing Unpaid Household Service Work.

34.89 While methods can be applied to estimate the monetary value of unpaid household service work, analysis

restricted to monetary values is unlikely to completely capture all the contributions to well-being of unpaid work at the individual, household and social level. In particular, unpaid household service work activities, just as with paid forms of work, not only affect significantly and contribute directly to the determination of personal capabilities and well-being outcomes, such as education and health, but unpaid household service work activities such as volunteering can also enhance people's opportunities to participate in social life. For that reason, a parallel physical time accounting method is also proposed as a better 'catch all' solution to measuring the household experience.

34.7634.90 The UN Guidance for the Valuation of Unpaid Household Work (UNECE, 2017) defines unpaid household service work as 'those economic services produced in the household and outside the market, but which could be produced by a third person hired on the market without changing their utility to the members of the household'. The definition excludes activities people can only perform on their own behalf, such as sleeping, other forms of personal care, and leisure. These activities lie outside the general production boundary. In the forms of work framework described above, unpaid household service work includes both services produced for own-final use and services produced for other economic units through volunteer work.

34.91 Accounting for unpaid household service work is focused on the measurement of various services. The table below provides a list of key groups of services. For each group there are additional details and specifications concerning the measurement boundaries and relevant treatments that must be considered which are described in relevant guidance material. Importantly, all of these services can have equivalent production activity that is undertaken as part of economic activity recorded in the sequence of economic accounts. Thus, it is not only the measurement of the volume of services produced at home that is of interest but also changes in the share of these services which is either produced for own-final use or purchased from other economic units.

34.7734.92 An important advance supporting the development of this list of services has been the adoption of the International Classification of Activities for Time-Use Statistics (ICATUS) 2016. ICATUS 2016 is consistent with the SNA to allow the derivation of aggregates for supplementary tables and is comparable with other existing national and regional time-use classifications. It was also aligned with the resolution concerning statistics of work, employment and labour underutilization, adopted by the 19th ICLS (2013). Although ICATUS codes are provided in table 34.5, it should be noted that time-use data may not always be the preferred data source. This is particularly true for infrequent activities such as forms of volunteering, where a longer reference period may be required to capture the activity effectively.

**Table 34.5: Types of unpaid household service work**

Area	ICATUS codes	Categories, descriptions and considerations
Childcare for own household or family	Division 41: <i>Childcare and instruction</i> . including Group 442.	Unpaid childcare captures the time provided by care givers caring for children within their own household or family. This can range from helping with homework to feeding, washing or dressing children. Meal production is excluded and would fall under the nutrition category. Unpaid childcare can be distinguished in many ways (such as active vs. supervisory, or physical vs developmental).
Adult care for own household or family	Divisions 42 <i>Care for dependent adults</i> and 43 <i>Help to non-dependent adult household and family members</i> , including Group 443 and Group 444.	Unpaid adult care captures activities where individuals are providing healthcare services, assistance with daily tasks, emotional support, or supervisory care to an adult within their own household or family, for example changing bandages or dressings or other medical assistance. Unpaid adult care may be provided on a temporary basis and to those who are potentially terminally ill and need long-term care.
Nutrition for own household or family	Division 31 <i>Food and meals management and preparation</i> .	Unpaid nutrition services include meal or drink production time, where it may be reasonable to expect that you could choose to order an alternative meal or drink from a market service.
Transport for own household or family	All activities under the following groups covering many purposes and modes of transport except walking (refer to ICATUS for details): Group 182, Group 250, Group 380, Group 441, Group 540, Group 640, Group 750, Group 860, Group 950	Transport associated with any other activity (paid work, leisure, personal care or unpaid work) but where the producer of those services was not paid for that time. Transportation services can include transport provided to others free of charge such as giving another person within the household of family a lift but can also include time where an individual transports themselves as opposed to paying for transport.
Household management services for own household or family	Divisions 32 ' <i>Cleaning and maintaining of own dwelling and surroundings</i> ', 33 ' <i>Do-it-yourself decoration, maintenance and repair</i> ', 35 ' <i>Household management for own final use</i> ' and 36 ' <i>Pet care</i> '	This includes activities such as cleaning the household, sorting out the household administration or bills, DIY repairs of the household, pet care and gardening. This category also includes the management of tasks classified under leisure activities, for example the time that a household member has invested in arranging/organizing a <del>tourism trip/holiday travel or accommodation</del> , but only when the activity meets the third-party criterion (i.e. that another person could have performed the task and obtained the same outcome).
Laundry and clothing services for own household or family	Division 34 <i>Care and maintenance of textiles and footwear</i> .	Unpaid laundry services involve the cleaning, ironing and drying of clothes, while the category can be extended to also include the unpaid repair of clothing.
Shopping for own household or family	Division 37 <i>Shopping for own household and family members</i> .	Shopping is an activity that can easily be contracted out, i.e., it meets the third-party criterion. Part of the labour involved in shopping involves the transportation of goods from the shop to the household. Internet shopping means online delivery services are displacing some of the household labour involved in shopping.
Information services for own household or family	This category is likely to be more challenging to capture effectively using the current time-use classification framework	With the expansion of the internet, there is now more scope than before for households to produce information for other households through digital platforms. These services do not have to be used by the consuming household to then produce another form of unpaid household production but could also be used as part of household leisure activities. The key criteria which defines whether the information produced is of value is whether the consumers of the information could have used a paid service for similar information.

Other unpaid household production not elsewhere classified for own household or family	Divisions 39 <i>Other unpaid domestic services for household and family members</i> ; 49 <i>Other activities related to unpaid caregiving services for household and family members</i> ; 59 <i>Other unpaid work activities</i>	An 'other' category is recommended to ensure that a complete accounting of unpaid household service work.
Organisation-based volunteering	Division 52 <i>Unpaid community- and organization-based volunteering.</i>	When households engage in volunteering through or for a charity of a not-for-profit organisation it is classified as organisation-based volunteering. Organisation-based volunteering may also be further split into different types of unpaid household service work.
Direct volunteering	Division 51 <i>Unpaid direct volunteering for other households.</i>	Where no organisation is involved, households providing voluntary services to other households are performing direct volunteering. Direct volunteering may also be further split into different types of unpaid household service work.

34.7834.93 Key variables of interest for each of the services listed above include: the time spent on each activity, the monetary value of production and the costs of goods and services used as inputs to production. An important connection in undertaking this accounting work is the ability to compare estimates of these variables with related entries in the sequence of economic accounts. Thus, for example, measures of time spent on these activities can be compared with measures of employment and other work on the same activities within the production boundary. To support comparisons, the valuation of unpaid household service work should apply the same exchange value ~~valuation~~ concepts as applied for non-market production within the SNA production boundary (see Chapter xx) and the costs incurred as inputs to production should be the same as those recorded as household final consumption expenditure (e.g. purchases of food, electricity, gasoline).

34.94 In addition to ensuring connection to the recording of activities within the SNA production boundary, the compilation of estimates on unpaid household services work should also ensure appropriate connection to work on other aspects outside the production boundary for which separate measurement might be undertaken. Examples include the measurement of health care activity, education and training activity (both discussed later in this Chapter) and free digital services (discussed in Chapter 22 on digitalization). In these cases, consistent treatment of expenditures, time-use and measurement scope will be of benefit in the compilation of accounts in terms of focusing measurement on common definitions and measurement boundaries and in improving the consistency in the interpretation of data by users.

34.95 The discussion above implicitly focuses on services produced by, and supplied to, members of the same household. However, in some instances it is relevant to measure the provision of unpaid services from one household to another. For example, the service flows between household units that are part of a wider family unit; or the service flows between households associated with direct and organization-based volunteering. The adjustments required to account for these flows between households will depend on the analytical focus and the scope of the underlying data.

34.96 In the case of organization-based volunteering, the output is measured at cost within the ~~core~~ SNA production boundary. In accordance with the *Handbook of National Accounting: Satellite Account on Non-profit and Related Institutions and Volunteer Work* (UN, 2018) volunteer output that exists outside of the SNA ~~core~~ production boundary can be valued using a replacement cost or generalist cost method for the volunteer's labour time. However, to avoid double counting estimates of the value of volunteering organizations contained within the ~~core~~ SNA production boundary, these estimates must exclude the value of any expenses or minor payments they receive in compensation.

34.97 Further, in accordance with SNA principles if volunteer ~~voluntary~~ labour were valued, the following accounting entries would also be necessary:

- remuneration of employees of the unit employing the volunteer labour;
- income for the household to which the volunteer belongs;

- a transfer of the same amount by the volunteer to the employing unit;
- final consumption expenditure of the employing unit;
- in relevant cases social transfers in kind from the producing unit to the households benefiting from the produced services, with a concomitant decrease of final consumption of the producing unit and an increase of final consumption by households.

34.7934.98 For a number of the services there are direct connections to other accounting-based approaches used for specific aspects of well-being. In the case of accounting for education and training and health care (Sections E and F), the accounts described can be extended to incorporate the production of the same services through unpaid household service work alongside the production through activities within the SNA production boundary. Thus, accounts for education and training can be extended to incorporate the unpaid household service work of childcare and accounts for health care can be extended to incorporate the unpaid household service work of adult care.

34.8034.99 Measures of unpaid household service work can also be used to extend the distributional analysis of income and consumption described in Section C. Thus, the measures of unpaid work can be broken down into different household groupings as proposed in that section – for example by income decile. Differences in the extent of unpaid household service work across household types will depend on the capacity of a household to pay for the same services on the market. Note that in an accounting approach, the measures of unpaid household service work will equally affect measures of household income and consumption since the supply and use of the services must balance.

34.8134.100 The development of accounts for unpaid household service work has been a long-standing field of national accounting. There are two sources of international guidance of particular importance for the measurement of unpaid household service work, the Guide on Valuing Unpaid Household Work (UNECE, 2017)<sup>6</sup>, and the UN Guide to Producing Statistics on Time-Use (UN, 2024). The first is of importance in providing an important step toward a harmonised international platform for measuring unpaid household service work. The second is of importance as it sets out best practice for the production of time-use surveys, which are typically the primary data source for the compilation of accounts for unpaid household service work.

34.8234.101 In broad terms two approaches have been developed for the measurement of unpaid household service work: the input approach and the output approach. The input approach brings together data on time use, wage rates and other inputs, while the output approach uses data on observed transactions and market prices for similar services purchased on the market. Details on applying these approaches are provided in the UNECE Guide on Valuing Unpaid Household Service Work (2017).

34.8334.102 In addition to measures in monetary terms, the accounting framing supports the presentation of non-monetary data about unpaid household service work including time spent. Additional insights into well-being are likely to be gained by disaggregating data by the socio-demographic characteristics of those people undertaking unpaid household service work, for example in terms of age (e.g. to support recording of the contribution of children to this work) and sex. In particular, it is highlighted that the production of unpaid household service work exhibits a distinctly gendered pattern in most countries due to prevailing social norms, with women undertaking the largest share of most unpaid domestic and care work. This in turn can significantly affect their overall well-being. Consequently, the compilation of accounts for unpaid household service work by sex is recommended.

34.8434.103 To support a general understanding of the potential organization of data on unpaid household service work, two tables are presented, one in monetary terms and one using time as the unit of measurement. Two basic decisions need to be made in relation to the granularity of the information on unpaid household service work. The first decision concerns the details on the characteristics of the people involved: sex, age category and/or level of education. This decision also depends on the granularity of data on paid employment, a topic discussed in Chapter 16 on the compilation of labour tables. This level of granularity is not reflected in the

---

<sup>6</sup> The work through the SNA update process has seen further advances in the compilation of unpaid household service work measures and an updated reference to best practice will be incorporated as it is finalised building on the content of the Guidance Note WS.3.

table below.

34.8534.104 The second decision relates to the allocation of the unpaid household service work to industries, and the detail of the industrial breakdown. The connection to industries allows investigation of the balance of production between unpaid household service work and that recorded in the sequence of economic accounts and changes in that balance over time, for example in response to changes in labour force participation leading to greater demand for child-care services. For this analysis, it is necessary to consider the level of industry detail used in the regular compilation of national accounts. The following high-level industry classes are considered most relevant in relation to unpaid household service work. The related unpaid household service activities are given in brackets and apply to both services for own use and volunteering where similar activities are being carried out<sup>7</sup>:

- Wholesale and retail trade; repair of motor vehicles and motorcycles (Unpaid household shopping services; Unpaid household vehicle maintenance services)
- Transportation and storage (Unpaid household transport services)
- Accommodation and food service activities (Unpaid household nutrition services)
- Information service activities (Unpaid household information services)
- Administrative and support service activities (Unpaid household management services)
- Education (Unpaid household developmental childcare or adult care)<sup>8</sup>
- Human health and social work activities (Unpaid household physical childcare or adult care)
- Other service activities (Unpaid household laundry services)
- Activities of households as employers; undifferentiated goods- and services-producing activities of households for own use<sup>9</sup> (Unpaid household service work not elsewhere classified)

34.8634.105 Table 34.6 presents an extended use table for unpaid household service work that highlights the key standard products of relevance that are recorded in use tables as well as additional unpaid services arising from unpaid household service work for own-use and from organization based and direct volunteering. The columns show the activities using unpaid household service work (which is shown as an “of which” amount) together with entries for final consumption expenditure and gross fixed capital formation. More detailed proposals and associated extensions are described in compilation guidance on unpaid household service work (reference to be finalized). recognizing that for certain entries data may not be available directly and assumptions and modelling will be required.

---

<sup>7</sup> Note that similar considerations need to be thought through regarding the breakdown of products represented in the rows of the use table.

<sup>8</sup> If developmental care cannot be differentiated then all adult and childcare can be aligned to ‘Human health and social work activities’.

<sup>9</sup> Although this category is described as ‘for own-use’, if there is volunteering that can’t be allocated to a particular type of unpaid household service work, then it may also need to be allocated to this category even though it would technically be better described as ‘for use by others’. If deemed preferable, an alternative might be to create another activity category to allocate volunteering activity that is not defined elsewhere.

#### 4. Other uses of time

[34.87](#)[34.106](#) Time-based accounting provides a more complete measure of how people's time is spent. Time based accounting is focused on how households allocate their time, including across the various forms of work, but also in activities outside of the general production boundary. Time based accounting is relevant because technical and organizational innovations shift economic activity, sometimes into, sometimes out of, the market (e.g., by substituting streaming services for cinema, private cars for public transport or vice versa, domestic washing machines for laundries, on-line flight booking services for travel agents, etc.) in a variety of ways.

[34.88](#)[34.107](#) To aid in measuring unpaid household service work, the UNSD has developed the International Classification of Activities for Time-Use Statistics (ICATUS) 2016, which provides a classification of all activities on which a person may spend their time over a 24 hour period. It is the standard classification of all economic and non-economic human activities, providing standardized concepts and definitions to support dissemination of internationally comparable time-use statistics.

[34.89](#)[34.108](#) A properly designed, nationally representative time-use survey (TUS), comprehensively covers all the daily activities of the population. A core feature of time-based accounting is the capability to map the activities of daily life to economic activity defined following the general production boundary. In addition, activities of people beyond the general production boundary, in particular non-productive activities undertaken by individuals, can be recorded. These activities include basic human activities such as eating, drinking, sleeping, leisure, exercising, etc.

[34.90](#)[34.109](#) There are some challenging conceptual aspects to reconcile in time-use measurement. For example, it can be difficult to differentiate the effects on well-being of unpaid household service work and leisure. Also, in some occupations at least, paid work has many of the affectively positive characteristics—challenge, sociability, enjoyment—often found in leisure pursuits. Further, it may be difficult in some instances to differentiate the primary use of time where people are, in effect, multi-tasking, for example when working from home and caring for children.

### E. Accounting for human capital, education and training activity and health care activity

#### 1. Introduction

[34.91](#)[34.110](#) The idea of viewing human knowledge and abilities as an asset – as human capital - and to estimate its value is not new, but has gained prominence in recent years, especially in the context of measuring sustainable development. Policymakers are calling for ways to understand and quantify human capital, in order to better understand what drives economic growth and the functioning of labour markets, to assess the long-term sustainability of a country's development path, and to measure the output and productivity performance of the education sector. Devising a robust methodology for the monetary valuation of the stock of human capital is important since studies, such as the World Bank Changing Wealth of Nations, suggest indicate that human capital is a significant component of extended measures of national net worth in many economies.

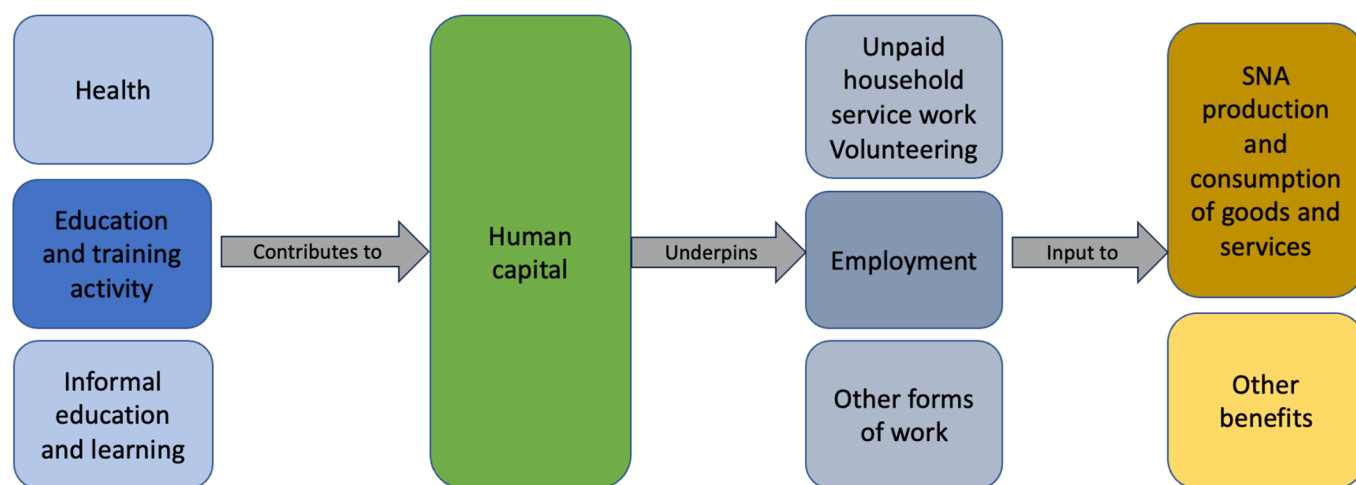

[34.92](#)[34.111](#) As well, there is considerable relevance of measures of human capital from the perspective of understanding the distribution of income and wealth, documenting the effects of changes in the age composition of the population on economic activity, understanding the implication for labour markets in light of ongoing changes in the economy through digitalization and globalization, and identifying the non-monetary benefits that may be obtained by society more generally from higher levels of human capital. Finally, in addition to measuring the stock and changes in stock of human capital, it is also relevant to organize data on investments in human capital, in particular, activity and expenditure on education and training.

[34.93](#)—The range of core connections and dependencies between human capital, education, labour and production, and other elements including health and unpaid household service work are depicted in the figure below. A key feature of this figure is that human capital is a core concept that underpins a range of aspects of well-

being. With this framing in mind, accounting for human capital is described in more detail in Chapter 35 alongside the other capitals that underpin the sustainability of well-being. This section describes approaches to account for two important contributors to human capital, education and training activity and health care activity. The measurement of other aspects in Figure 34.2 is discussed in Section D above concerning the contributions of unpaid household service work and other forms of work and in Chapter 16 concerning Labour market tables. provide a conceptual framework through which labour market data from diverse sources can be confronted and integrated, with the aim of producing a coherent and consistent set of labour market statistics. Broadly, labour tables consist of four quadrant tables: jobs, persons (both employees and self employed), volume (i.e. hours worked) and payments. Chapter 16 provides a thorough overview of labour tables.

34.112

**Figure 34.2: Linking education, human capital, employment and production**

34.94 This section describes the potential to connect data on labour, human capital and education. Labour tables provide a conceptual framework through which labour market data from diverse sources can be confronted and integrated, with the aim of producing a coherent and consistent set of labour market statistics. Broadly, labour tables consist of four quadrant tables: jobs, persons (both employees and self employed), volume (i.e. hours worked) and payments. Chapter 16 provides a thorough overview of labour tables. The following two sub-sections present approaches to accounting for human capital and accounting for education and training.

## 1. Accounting for human capital

34.95 A general definition of human capital is “the knowledge, skills, competencies and attributes embodied in individuals that facilitate the creation of personal, social and economic well-being”.<sup>10</sup> This definition provides a clear foundation that incorporates both economic and non-economic benefits arising from the use of human capital by individuals. From an economic perspective, the creation of human capital, or put differently, the acquisition of knowledge, skills, competencies and attributes, increases the productive potential of the individuals in an economy and is a source of future economic benefit to them. Critical inputs to the creation of human capital are education and training but the consumption of these inputs is not sufficient. In addition, creating human capital requires the assembly and processing of these inputs by the individuals consuming them with the result that each individual creates a unique set of capabilities.

34.96 From an SNA perspective, there has been a long-standing discussion on the potential to capitalize education and training expenditures within the sequence of economic accounts and recognize human capital as an economic asset on the balance sheet. Thus, although human capital has not been included in the sequence of

<sup>10</sup> OECD, 2001.

economic accounts, the discussion here is of high relevance for extending and broadening the sequence of economic accounts. This section provides a description of ways in which the sequence of economic accounts can be connected to additional data on human capital.

- 34.97—Considering human capital as an economic asset leads to two approaches by which human capital may be valued in monetary terms. The first approach is a cost-based approach which sums the costs of generating human capital, principally expenditures on education and training. To apply this approach, the extended accounts for education and training described in the next section organize the relevant input data. The second approach is the lifetime labour earnings approach which estimates the value of human capital by calculating the net present value of future earnings of individuals within an economy. Both of these approaches inherently have a focus on the economic benefits arising from human capital, i.e. the contribution of labour to production within the SNA production boundary. While not elaborated here, a broader focus is possible incorporating the contributions of human capital to unpaid household service work, including volunteering, and the non-economic individual and societal benefits of human capital, e.g. in terms of civic engagement and participation.
- 34.98—The UNECE Guide on Measuring Human Capital (2016) provides a thorough description of these two approaches and the discussion here summarizes the key aspects. From a theoretical point of view, the net present value based approach is the most appropriate, as it incorporates all future economic benefits that can be allocated to the relevant asset, thus replicating a market equivalent valuation. However, its measurement requires a number of assumptions on the future development of the (active) population and the future pattern of economic benefits. The total values can also be significantly affected by the discount rate that is applied. To complement estimates from the net present value approach, a cost-based approach can be applied using the perpetual inventory method (PIM). In this approach, the investment costs for creating human capital are summed to obtain an estimate of the value of the human capital. These costs do not only relate to formal education, but also include training and courses provided by employers; time spent on learning and studying at home; and other expenditures on, for example, school books and other training material. This method also requires several assumptions, for example on the distinction between expenditures that are current nature and expenditures which add to the stock of human capital. Also, assumptions are needed to measure and to value any unpaid activities and concerning the service lives and the depreciation pattern of human capital.
- 34.99—Table 34.7 provides a structure for presenting data on human capital and related variables.

**Table 34.7 Summary human capital table**

		Employment	Hours worked	Remuneration	Human capital -	Human capital -
		by ISIC	by ISIC	of employees	Lifetime labour	Cost-based PIM
		by ISIC	by ISIC	by ISIC	earnings	by ISIC
		Number people				
		employed	Hours	Monetary	Monetary	Monetary
Total						
By individual characteristic						
	Age					
	Sex					
	Education status					

- 34.100—In applying both approaches there are a number of measurement challenges described below which must be considered by compilers.

- The development of human capital takes place over a long but varying length of time, indeed, potentially over a life time, which complicates the determination of the timing of investment (and the contribution of individual years).
- The development of human capital relates to the input of education and training provided by other economic units but will also be built through personal experiences and unpaid inputs (unpaid household service work) of family and friends.
- The use of human capital in production is limited by the amount of time that a person provides labour input but the precise pattern of that use varies over time and hence the way in which human capital depreciates needs to be considered. The variation in the pattern of use will also affect the determination of asset lives.
- Depending on wider economic and social conditions, certain skills and knowledge may become obsolete from an economic perspective, for example through changes in technology.
- There is a very large heterogeneity in individual's combination of skills and experience and how these align to particular occupations and industries.
- The quality of educational experiences and the impact of education on the development of human capital varies across individuals and may not be directly related to the volume or cost of education.
- There are additional benefits (known as spillover effects) when knowledge and experience is shared among employees in a work place which in turn challenges the ability to use the sum of measures of human capital of individuals to reflect the aggregate contribution of human capital.

34.101—These challenges are real but also exist for many assets within scope of the SNA sequence of accounts. The primary issue for compilation is therefore the extent to which appropriate assumptions can be determined to provide reasonable estimates of human capital to support discussion and analysis. In this context, while the focus of discussion here is on the estimation of a monetary value of human capital, it is essential to collect a substantial range of non-monetary data to support measurement and the testing of assumptions. Relevant non-monetary data include data on years of education, the number of people in different professions, and the levels of skills and experience. In that regard, accounting for human capital provides a framework for the organization of an array of data building on the labour tables (Chapter 16) and the extended accounts for education and training described below.

34.102—While there are challenges in the measurement of human capital and ongoing research is encouraged, these practical concerns are not the primary reason for exclusion of human capital from the SNA sequence of economic accounts. One long-standing conceptual concern is that although the treatment of expenditure on education and training as analogous to gross fixed capital formation is possible, the nature of the acquisition of the benefits of education and training is such that they are activities that cannot be undertaken by anyone else on behalf of the student. Thus, the acquisition of knowledge is not a process of production in and of itself, even though the instruction conveyed by education services is. The consequence is that human capital cannot be considered produced. The more recent investigation into knowledge products and the capitalization of intangibles such as marketing assets suggests that this concern about whether human capital can be produced merits further investigation.

34.103—Another conceptual concern has been the question of ownership rights and the extent to which human capital is capable of bringing economic benefits to its owner, as required to satisfy the definition of economic assets. This concern connects the question of ownership of human capital to the problematic idea that people are “owned”. However, an alternative framing is that human capital is embodied in individuals who in effect own their skills, knowledge and experience and utilize these capabilities to secure future economic benefits for themselves. Again, there is merit in further investigation.

34.104—Notwithstanding these specific conceptual concerns, it must be recognized that establishing human capital as an asset within the sequence of economic accounts would have substantial implications for the structure of the accounts and the interpretation of traditional measures of consumption, income, investment and saving, especially for the household sector but also more broadly. Resolving these implications requires determining the appropriate accounting entries to show that those paying for the development of human capital (e.g. governments, corporations) transfer the accumulation of benefits to the individuals whose human capital is

enhanced. The interpretation of remuneration of employees also needs consideration since in a human capital framing this flow would represent a payment for services. While accounting solutions to these types of changes have been developed, a wider discussion of the potential changes to the sequence of economic accounts and the implications for key economic measures and their interpretation is required.

~~34.105~~ Finally, the measurement of human capital allows for connection to a range of other topics that are important for individual human capital accumulation. These include health, parental and family engagement, cultural and social engagement and wider work related human capital accumulation beyond in-work training.

~~34.106~~ Health is a key aspect of an individual's human capital. This includes, for example, the effect of the lack of various diseases, illnesses and disabilities providing a higher level of physical and cognitive skills directly, as well as enabling further development into the future. Conversely, lack of good health can be seen as an impairment of an individual's opportunity to develop, while also having a detrimental impact on an individual's human capital today. Better health can also support the longer use of an individual's human capital, whether in the marketplace or in wider economic activity.

~~34.107~~ Similarly, people's family situation, and the cultural and social activities people engage in both as children and adults (e.g. attending museums, participating in social clubs, undertaking personal projects) are known to influence people's cognitive, physical, social and emotional development. While all of these factors will influence the development of people's human capital, the mechanisms by which this occurs is an area of active research (e.g. determining the relative role of parental income versus the opportunities such income provides). In addition, incorporating these issues within either an income-based or cost-based approach requires further discussion both in terms of valuation concepts and regarding data sources to support international comparability.

~~34.108~~ Lastly, beyond the wider social aspects feeding into human capital investment, it is known that there are other mechanisms that influence a person's development in the workplace. In particular, support networks, mentorship opportunities, and the quality and quantity of feedback on a person's work allow them to improve their skills and knowledge, and hence their potential human capital. There are also aspects of the extent to which employees are encouraged and extended in their work, while also being supported, so that they are able to improve their marginal productivity. All of these concepts are clearly important in the aggregate, but due to measurement issues, such as how to convert such opportunities above as intangible 'investment' when there is no market transaction, and what the imputed transaction may need to be, mean this is still an active research area.

~~34.109~~ Collectively, all of the topics introduced in the paragraphs above describe a large research agenda. Thus, notwithstanding the significant progress on accounting for human capital that provides a strong foundation for measurement, there remain many areas in which additional investigation and testing should be undertaken to more fully harmonize and integrate the accounting required for the development and contribution of people's knowledge, skills and experience.

## **2. Accounting for education and training activity**

~~34.110~~34.113 There have been a number of projects undertaken to develop international guidelines on accounting for education and training activity. Examples include the UNESCO Methodology of National Education Accounts (NEA), the UNESCO-OECD-Eurostat (UOE) Manual for data collection on formal education and the OECD publication "Education at a Glance". The NEA framework and the UOE data collection on formal education support compilation of coherent and internationally comparable data. However, they both have elements that differ in several ways from SNA principles and measurement boundaries.

~~34.111~~34.114 To support SNA consistent compilation, the UNECE Satellite Account for Education and Training (SAET): Compilation Guide can be used. This extended account uses the national accounts and the relevant data input and classification systems (e.g., education statistics, government finance statistics, COFOG and COICOP statistics, trade-in-services statistics) as a starting point with the supply and use tables acting as a framework for ensuring consistency. In addition, the extended account incorporates a detailed classification of education and training activities by purpose based on International Standard Classification of Education, 2011 (ISCED).

~~34.112~~34.115 The scope of the extended account for education and training activities, as described in the SAET, covers all public and private expenditure for formal education and vocational training. Thus, the expenditure for education and training activities includes the following items:

- Teaching, administrative and other activities in formal education and vocational training services;
- Non-formal cultural, recreational, sport and vocational education and training activities (also including free courses and e-learning);
- In-house training by employers;
- Associated goods and services directly related to the delivery of education and training services;
- Gross fixed capital formation in the education industry.

~~34.113~~34.116 The extended account includes the expenditures on education and training for all residents of a country, as required for the measurement of investment in human capital. In line with this intention, the accounts encompass expenditures related to domestically produced education and training, as well as imported services (i.e., resident students studying in other countries). Expenditures of non-resident students within a reference country contribute to the human capital of another country and are recognized as exports.

~~34.114~~34.117 The extended account on education and training uses the supply and use framework as the starting point for the organization of data. Compiling data from both supply and use perspectives allows confrontation of the alternative data sources and improves the quality of the account. Four core tables can be distinguished (add reference):

- Education and training output, by provider and education and training purpose
- Education and training expenditure, by purchaser and education and training purpose
- Financing, by sector and education and training purpose
- Cost structure, by education and training purpose

~~34.115~~34.118 These four tables present monetary data in current prices focusing on the production aspects of the education system. They are intended to reconcile with relevant aggregate entries in the sequence of economic accounts given that the expenditures incurred by the different economic units within the activity of education and training are part of their production costs and are linked to their activities as providers of educational goods and services. Depending on country circumstances and data availability more detailed breakdowns can be compiled. Table 34.8 provides a basic supply and use table showing types of education and training services. Total supply is categorized in terms of different institutional sectors with a key distinction between non-market (general government and NPISH) and market producers. Total use is categorized by users of final consumption and intermediate consumption.

**Table 34.8 Basic Education and training expenditures supply and use table**

Supply table										
			Government			NPISH	Market producers - Education industry	Other market producers	Imports	Taxes less subsidies on products
			Central	State	Local					<b>TOTAL SUPPLY</b>
<b>Education and training purpose</b>										
	EP0	Pre-primary education								
	EP1	Primary education								
	EP2	Secondary education								
	EP3	Higher education								
	EP4	Cultural, sport & recreation education								
	EP5	Other educational & vocational training								
	EP6	In house training								
		Associated products & admin expenditures								
<b>TOTAL OUTPUT</b>										
R&D production of Education industry (ISIC85)										
Use table										
			Final consumption expenditures				Intermediate consumption - market producers		Exports	
			Government			NPISH	Households			<b>TOTAL USE</b>
			Central	State	Local					
<b>Education and training purpose</b>										
	EP0	Pre-primary education								
	EP1	Primary education								
	EP2	Secondary education								
	EP3	Higher education								
	EP4	Cultural, sport & recreation education								
	EP5	Other educational & vocational training								
	EP6	In house training								
		Associated products & admin expenditures								
<b>TOTAL OUTPUT</b>										

~~34.116~~34.119 Where possible, estimates of output, expenditure and costs should be presented in volume terms using appropriate methods and consistent with the advice on price and volume measurement in Chapter 18. While the extended accounts for education and training largely respect the SNA production boundary for education and training, compilers of these accounts are encouraged to expand the production boundary to include the output from enterprise's internal expenses on in-house training (own account training). The aim of this extension is to provide policy makers with additional data on the expenditures on education and training, and the financing of these expenditures.

~~34.117~~34.120 The monetary data presented in the main tables should be supplemented with non-monetary data concerning: population, the number of enrolled students (by ISCED level), the number of adults in continuing vocational training and in lifelong learning (broken down by sex and age group), the number of (and hours worked by) teachers/staff (by ISCED level) and the number of employed persons in education and training by educational attainment. Combining monetary and non-monetary data sets supports cross-sectional analysis of expenditure per capita or per student which in turn provide important insights for policy measures. Examples of non-monetary tables are presented in SAET Section 3.6.

~~34.118~~34.121 A final extension concerns data on the provision of early childhood education which will commonly involve unpaid household service work and hence is outside the ~~scope of the~~ SNA production boundary. An extension to consider the role of unpaid household service work might also extend to recognize the contribution of other unpaid household service work activities that support the development of human capital such as those relating to childcare, nutrition and information services. Estimates concerning ~~these~~ activities can be incorporated in the SAET framework recognizing the challenges involved in measuring and valuing unpaid household service work as described in Section C.

### 3. Accounting for health care activity

~~34.119~~34.122 Since health is a fundamental aspect of people's well-being, and can be directly connected to the development and enhancement of human capital (see Figure 34.2), it is important to have detailed insights concerning the production and outputs of the health care systems in countries, the economic units involved, and how health care activity being financed. While there is a range of data in the sequence of economic accounts related to health care activity, for example expenditure data classified using COFOG and COICOP, ~~the~~ development and implementation of health accounts has been a long-standing activity for this wider purpose. It is recommended that to support integrated decision making, countries compile a series of extended accounts that present data on the functions, providers and financing of health care systems. The standard for accounting for health care is described in the *System of Health Accounts 2011 (SHA)*. The SHA is a well-developed framework for classifying health expenditures on these different aspects of the health care system.

~~34.120 As introduced in Chapter 2 and noted elsewhere, the SNA has a focus on the measurement of outputs from economic activity rather than outcomes. As a result, the SNA does not organize data within the sequence of economic accounts that supports measurement of, for example, the quality of life of households. Further, as noted in Chapter 2, the measurement of well-being discussed here concerns objective rather than subjective measures.~~

~~34.121~~34.123 The extended accounts for health are organized around a tri-axial system, defining (i) consumption of health care goods and services by function; (ii) provision of health care services by industry; and (iii) financing of health care (i.e., sources of funding). What is consumed must be produced, meaning that setting up the system within a supply and use framework is a useful tool for ensuring consistency and completeness. As well, what is produced and consumed must be financed and hence a clear link and consistency can be established among the three axes.

~~34.122~~34.124 The three axes each have their own classifications. The three key classifications in the extended accounts for health are the classification of health care functions (HC), the classification of health care providers (HP), and the classification of health care financing schemes (HF). Classifying the consumption of goods and services according to health care functions is the starting point for compilation and defines the boundaries of the health accounts.

~~34.123~~34.125 Health care functions relate to "what is the purpose" or "the type of need a transaction or group of transactions aims to satisfy". This is the most fundamental classification within the extended account for

health and defines what is in and out of scope for “health care”. There will always be borderline cases between health care and social care especially concerning long-term care (LTC). The extended accounts for health distinguish two elements of LTC: (i) health: medical or nursing care including the management of symptoms involving medical, paramedical and nursing care services, such as relieving pains or other symptoms, administering medication, performing medical diagnosis and minor surgery, dressing wounds, etc, as well as personal care services provided in response to limitations in self-care primarily due to disability and illness; and (ii) social: assistance services related to care that enables a person to live independently in a house or apartment, i.e. lower-level social care services to assist with instrumental activities of daily living. The extended accounts for health include LTC (health) within its scope of health expenditures but it is also recommended to measure the expenditures related to long-term care (social) to complement the health data.

~~34.124~~34.126 The extended accounts for health also provide a framework for the classification of health care goods and services, as described in Annex E of SHA 2011. The primary use of the product classification is to facilitate applying the measurement boundary and to select the products for estimating health care expenditures. The product classification in the extended accounts is linked to the Central Product Classification (CPC) and thus to the supply and use framework in the national accounts.

~~34.125~~34.127 Table 34.9 provides a basic supply and use table for recording health care output and expenditure according to classes of health care functions (HC) and classifying supply in terms of health care providers (HP) and use in terms types of users.

**Table 34.9 Basic Health care expenditures supply and use table**

[illegible]

~~34.126~~34.128 Household production of health care can be included in extended accounts. In the SHA this inclusion is limited to those health services whose costs are partially or completely covered by dependency allowances. The associated transfers are treated as a quasi-salary and a corresponding “output value” is calculated. The wider literature supports the view that unpaid household care has a significant role in understanding health and social conditions and individuals’ well-being. Thus, it is recommended that all unpaid household production of health and social care, and not limited to what is already recorded in the SHA, is included in the extended accounts. This work should be undertaken in line with the discussion in Section C.3 on the measurement of unpaid household service work, noting the importance of distinguishing between health care and other care activities and also clarifying the role of supervisory care.

34.129 To support the reporting on and discussion of well-being, indicators for health and social care can be built from the expenditure flow data in the health care accounts. These indicators include individual final consumption expenditures of health and social care with various breakdowns defined mainly by health care function, provider, and financing scheme. ~~In “Final” consumption expenditure in the extended accounts, the relevant expenditures~~ also includes intermediate consumption related to occupational health care. Where possible, measures in volume terms should be derived consistent with best practice described in Chapter 18. Data can also be cross tabulated according to different variables (e.g. household type) to support a range of analyses of household well-being.

~~34.127~~34.130 In monetary terms a core set of indicators includes health expenditures as a share of GDP, per capita health expenditures, expenditure by health care function, expenditure by age and gender of beneficiaries, and expenditure by income group of beneficiaries. In non-monetary terms indicators include employment in health and social care with breakdowns by age, sex, employment status and other characteristics. Employment data classified by occupation can be compiled following the International Standard Classification of Occupations (ISCO-08) noting the most relevant ISCO groups for health are sub-major group 22 (health professionals) and 32 (health associate professionals). Physical indicators of assets used in the production of health service can also be presented (e.g., number of hospital beds available).

## Chapter 35: Measuring the sustainability of well-being

(new chapter)

08.1

### A. Introduction

- 35.1 Sustaining and increasing levels of well-being for populations as a whole, for groups within those populations and for future generations is at the heart of sustainable development. Chapter 2 (section B.1) describes the conceptual Building-on-the-framing for the measurement of sustainability and well-being that is applied in the SNA. The framing recognizes the links to the concept of sustainable development and the need to consider both current well-being and the well-being of future generations and including the distribution of well-being across population groups. The topic of sustainability emerges in relation to the well-being of future generations presented in Chapter 2 (section B.1), measuring the sustainability of well-being requires introducing a time dimension, i.e. assessing whether the capacity of a country or community to provide well-being can be secured in the future. As introduced in Chapter 2, from an economic and accounting perspective, the capacity to provide well-being in the future is most readily interpreted in terms of the capital available to underpin future well-being with the relevant stocks of capital encompassing economic, natural, human and social capital.
- 35.2 From the perspective of economic theory, the rationale underpinning a capitals approach to assess sustainability is that non-declining real wealth per capita (i.e. the available stock of capital per person) is a necessary condition for past development to be considered sustainable (Arrow et al, 2004; Dasgupta, 2001). An alternative expression of this theory is that if real wealth per capita has declined then past development should not be considered sustainable, noting that relatively larger increases in real wealth do not imply situations are relatively more sustainable. This economic rationale underpins the work of the World Bank, the United Nations Environment Program, various national statistical institutes and others UNEP in their measurement of comprehensive and inclusive wealth accounts (see Chapter 2, Box 1 for references). These measurement efforts — i.e. by tracking the change in wealth of countries in real terms for multiple capitals to gain insights — can be gained on into the sustainability of those countries' capacity to in providing well-being in the future. Work on wealth accounting reinforces the importance of considering stock measures in both physical (quantitative) and monetary terms for the assessment of sustainable development thus moving beyond and not limiting analysis that considers only — to flow measures of production, income and consumption, such as gross domestic product.
- 35.3 The use of a capitals approach to assess sustainability provides a broad and structured framework that is grounded in economic theory and can provide a starting point for the assessment of sustainability. However, it cannot be considered an all-encompassing approach. Two general limitations are noted here. First, not all relevant aspects of well-being and sustainability will fall within scope. Chapter 2, Box 1 lists a number of well-being and sustainability measurement initiatives some of which apply or recommend a capitals approach but a number of which do not. The existence of a variety of approaches is not surprising since given that whether a given entity, context, region or country can be considered sustainability in any given context depends on a wide range of factors including the preferences and aspirations of people. Second, ideally the use of an indicator of real wealth requires a complete coverage of stocks of capital as well as high levels of detail about specific assets. This allows an — such that the aggregate indicator of real wealth to can track substitution across stocks of capital over time. An indicator of this type then allows supports assessment of weak and strong sustainability (discussed further in Section F). In practice, both the scope and the level of detail for the measurement of real wealth may be more limited than ideal.
- 35.4 Notwithstanding the limits of a capitals approach to in providing definitive statements on about sustainability, a capitals approach has the distinct advantage of also being able to provide a structured basis for the organization of a relatively comprehensive set of information on sustainability. Thus, this chapter uses the four capitals – economic, natural, human and social – as the starting point for describing accounting approaches for the organization of relevant data. — which, in turn, this provides the capacity for decision makers and analysts to assess sustainability according to their own assumptions and framings. Put differently,

accounting can underpin frameworks within which data about the quantity, quality, condition and monetary values of the capitals can be placed in a common context. The subsequent assessment of the effects of future changes in the composition of the capitals and the associated implications for well-being is a task allocated to analysts.

- 35.5 ~~T~~~~At the same time, it is noted that t~~he development of an historical time-series of descriptive information about the various types of capital as provided through the implementation of accounting approaches, can itself help to underpin the development of alternative framings and interpretations of sustainability, for instance by providing data on the extent to which a stock of capital has been maintained or there has been substitution across types of capitals. For example, ~~accounting a range of~~ data about stocks of natural capital in physical terms can inform the assessment of sustainability in combination with information on environmental thresholds and limits (e.g. from using the planetary boundaries framework, Rockstrom et al, 2009).
- 35.6 A focus on measuring the various capitals using an accounting approach has two related advantages. First, within an accounting approach the measurement of stocks is undertaken in a coherent manner with the measurement of flows. Thus, information about the benefits (and loss of benefits) arising from the use of the stocks of capital can be linked to those stocks. In a system wide context, the mapping of benefit flows associated with different capitals and across multiple locations and economic units provides a rich information set. Second, the information is organized such that it supports ~~communication~~ description of the relationship between investing in stocks of capital (e.g. through education, restoration of ecosystems, facilitating social networks) and the maintenance of benefits from those stocks into the future and facilitates analysis of appropriate policy responses. ~~of the narrative that failure to invest and maintain the stocks of capital (leading to their depreciation, depletion or degradation) implies a loss of benefits from those stocks in the future; and supports the policy response narrative that investing in stocks of capital (for example through education, restoration of ecosystems, facilitating social networks) is appropriate to secure benefits in the future.~~
- 35.7 Within this broad setting of sustainability, this chapter introduces a range of material relevant to the measurement of stocks of capital, both in the context of the SNA sequence of economic accounts and in related accounting frameworks. Section B considers the general descriptions and measurement boundaries for the different types of capital and clarifies the connection to the asset boundary of the SNA. Section C provides a more extensive introduction to the measurement of natural capital as undertaken in the System of Environmental-Economic Accounting (SEEA). Sections D and E discuss the measurement of human and social capital. Section F discusses a number of measurement considerations concerning capital related concepts, such as capacity and resilience, connections to financial assets and issues in valuation.

## **B. Descriptions and boundaries in measuring types of capital**

- 35.8 This section considers the general descriptions and measurement boundaries for the different types of capital and clarifies the connection to the asset boundary of the SNA. Commonly in economics and accounting the terms capital and asset are used interchangeably. For example, in the SNA investment in fixed assets is referred to as gross fixed capital formation. In the discussion here the term capital is used to refer to broad groups of individual assets which can all be characterized in general terms as entities that provide benefits in the future. Data about the different capitals and the individual assets can be presented in physical (quantitative) terms or monetary terms. The term “stocks” is used where the focus is on physical or quantitative aspects.

- ~~35.8~~35.9 The SNA's sequence of economic accounts incorporates measures concerning a range of different types of capitals within its balance sheet and associated accounts. ~~In the broadest terms, t~~The scope of the sequence of economic accounts encompasses all stocks of capital that satisfy the definition of an economic asset in Chapter 11. This scope covers stocks of produced non-financial assets (including fixed assets and inventories), non-produced non-financial assets (including purchased goodwill and marketing assets), natural resources (i.e., natural capital excluding ecosystem assets, covering, for example, land, mineral and energy resources and timber resources) and financial assets and liabilities. A complete description of all ~~of the~~ components of the SNA balance sheet is provided in Chapter 14.

~~35.9~~35.10 Critical to the discussion in this chapter is that the scope for measurement of assets in the SNA is determined with a focus on the monetary value of the stock of capital which is assessed in terms of expected future flows of (i) benefits arising from goods and services within the production boundary; and (ii) benefits from monetary transactions in assets (e.g. sales of land) or received as property income. Further, the scope of the SNA balance sheet is limited to those assets over which economic ownership is established, including those assets subject to collective ownership by government on behalf of society generally.

~~35.10~~35.11 From a sustainability measurement perspective, this scope supports analysis of, for example, the extent to which the level of investment in fixed assets is sufficient to both offset depreciation of those assets and underpin future production of goods and services. Such analysis might be applied in the context of individual industries or institutional sectors and can also be considered in the context of investment in specific asset types, such as public infrastructure delivering public goods such as roads and telecommunications networks. However, as introduced in Chapter 2, while this scope of measurement and analysis is important, it is not complete with respect to sustainability since there are a wide range of other factors that should be considered.

~~35.11~~35.12 To support wider measurement and analysis of sustainability, four types of capital are identified: economic capital, natural capital, human capital and social capital. Within this typology, the SNA's balance sheet includes economic capital (see section B.1 below) and some aspects of natural capital. Using a wider coverage of capitals, i.e. beyond the SNA balance sheet, provides an improved base for the analysis of sustainability. The wider coverage ~~and~~ recognizes explicitly, that other aspects of natural capital, such as the contributions non-market values of ecosystems to well-being that are not exchanged in markets (e.g. water purification, coastal protection), and the stocks of human and social capital are important considerations. Figure 35.1 provides a summary of the different components of the four capitals and the following sections provide additional details on the relevant measurement boundaries for each type of capital.

**Figure 35.1: Components of four capitals**

Type of capital	Main components	Links to SNA and SEEA measurement boundaries	
		SNA	SEEA
Economic capital	Produced assets ( <u>excl. biological resources</u> )	SNA-Assets in the Sequence of Economic Accounts	
	Non-produced assets (excluding natural resources)		
	Financial assets and liabilities		
Natural capital	Natural resources, <u>incl. all biological resources</u>		SEEA Environmental Assets
	Ecosystem assets		<u>Individual natural resources</u> <u>Ecosystem assets</u>
Human capital			
Social capital			

~~35.12~~35.13 Accounting for different types of capitals should also encompass measurement beyond the monetary value of stocks of capital. ~~Three-Four~~ additional considerations are of particular relevance ~~and are also described in the following sections~~. First, for all capitals, accounting for the stocks in physical terms and organizing relevant information on the quality, condition and composition of the stocks is fundamental to both the valuation of the stocks and to understanding the sustainability of those stocks, i.e. their capacity to contribute to well-being in the future. Of particular importance in assessing this capacity is understanding the physical thresholds and limits of different types of capital. For example, assessing the capacity to sustainably harvest fish stocks will include, among many other factors, consideration of the size and age structure of the fish stock and the potential rate of replacement of the stock.

~~35.13~~35.14 Second, there are flows associated with each stock that are recorded in the sequence of economic accounts and data on these flows will be relevant in supporting an understanding of the changes in the stocks over time and the associated connections to well-being. For example, in relation to human capital, although the stock is not included in the SNA balance sheet, the sequence of economic accounts records flows of remuneration of employees and expenditure on health care, education and training.

35.14—Third, while some flows associated with each stock are recorded in the sequence of economic accounts, all stocks of capital have ~~other associated~~additional flows that should be considered in a complete assessment of sustainability. These additional other flows ~~include a range of benefits that~~ lie outside the SNA production boundary and include such as ecosystem services generated by natural capital (i.e. the contributions of ecosystems to the benefits that are used in economic and other human activity (SEEA Ecosystem Accounting, para 2.14)), unpaid household service work (including volunteering contributions), and intrinsic values associated with historic and heritage sites.

35.15 Recording information about ~~gnizing~~ these flows, in particular those beyond the SNA production boundary, facilitates a wider discussion on sustainability since the implications of policy choices and investment decisions can be considered more holistically.

35.16 Also relevant for the analysis of sustainability is information on ~~Other flows of interest related to capitals also include those~~ concerning negative effects on stocks of capital such as flows of pollutants and emissions. These flows which can reduce the condition of human capital (e.g. through impacts on human health), fixed assets (e.g. through damage to buildings) and ecosystem assets (e.g. through reduced water quality in rivers). Many of these flows can be recorded using accounting frameworks and thus can readily complement the data in the sequence of economic accounts (e.g. by recording data on flows of pollution by industry). ~~Flows of both economic benefits within the SNA production boundary and other benefits such as those listed above will be affected by changes in the condition of stocks of capital.~~

~~35.16~~35.17 Fourth, the assessment of well-being and its sustainability must also consider the distribution of capitals and the associated benefits. This topic is most commonly considered in relation to the distribution of income, consumption and wealth across different household groups. Chapter 32 on Households provides a discussion on distributional accounts for households within the sequence of economic accounts and Chapter 34 on Measuring well-being considers the potential to extend these accounts to encompass other stocks and flows such as the distribution of unpaid household service work and consumer durables. Distributional accounts for wealth are not considered further in this chapter.

~~35.17~~35.18 In the following sub-sections, each type of capital is described in turn. This is an understandable structure and is commonly applied in the measurement of capitals, for example in wealth accounting. However, this structure serves to hide the fundamental connections that exist both within each type of capital and among different types of capital; connections which will vary across locations and over time. Thus, while accounting for each of the stocks of capital on its own provides a strong baseline of information, the assessment of sustainability in any given context must consider the (likely non-linear) interactions that are expected to emerge in the future and also consider the different ways in which each capital contributes to well-being in any given context. Further, there will be considerable support for analysis and interpretation in providing as fine a level of detail as possible about all types of capital (e.g. in terms of age, location and ownership). For this reason, the aggregation across capitals and interpretation of any balance sheet values in monetary terms, should be undertaken cautiously and using as much complementary data as possible, for example concerning the age and condition of the stock.

## 1. The scope of economic capital

~~35.18~~35.19 *Economic capital refers to the stock of economic assets that are created through the direct involvement of economic units and which are under the control of an institutional unit, either individually or collectively.* The scope of economic capital includes:

- Produced assets, including fixed assets, inventories, and valuables but excluding ~~cultivated~~ biological resources which are included under natural capital. There are many types of produced assets including buildings, machinery and equipment, infrastructure such as roads, dams and airports, and intellectual property products (e.g. software and artistic originals).

- Non-produced non-financial assets such as contracts, leases and licenses, marketing assets and purchased goodwill but excluding natural resources (and any associated resource leases) which are included under natural capital.
- Financial assets and liabilities.

35.1935.20 Economic capital is a simplifying label to refer to this set of assets. It is useful in the context of discussing sustainability to support communication of the distinction between these assets and the other types of capital. Other labels are also used to refer to this set of assets, most commonly produced capital, but also man-made capital, manufactured capital and built capital. The label “economic” is applied in an SNA context to support a distinction from the long-standing SNA term “produced assets”. Importantly, the use of the label “economic” does not imply that the other types of capital have no economic value and it is noted that some aspects of natural capital are included in SNA balance sheets (see Figure 35.1). The general literature on economics recognizes that natural, human and social capital all generate benefits even if these benefits are not captured within the SNA production boundary.

35.2035.21 The definitions, measurement boundaries and accounting treatments for all of the components of economic capital are thoroughly explained in relevant chapters of the SNA – in particular chapters 11 - 14. In relation to the measurement of the relevant stocks, the discussion in chapter 17 is most relevant as it describes the concepts and methods for estimating balance sheet values in monetary terms of produced assets (commonly referred to as the “capital stock”), ~~non-produced non-financial assets~~ and associated measures of capital services (including depreciation and depletion).

35.2135.22 The measurement of balance sheet values in monetary terms for produced assets is generally dependent on non-monetary information (or assumptions) about the stock including its age, its expected life and its pattern of contribution to production over time. In addition, using information on the prices of produced assets, it is possible to derive estimates of the volume of the stock of produced assets, i.e. the quantities of the stock weighted by their relative prices. As described in the introduction, indicators of changes in the volume of stock (commonly referred to as real changes), are of direct relevance in the analysis of sustainability and productivity.

35.2235.23 For the assessment of sustainability, it will also be relevant to present separately the non-monetary information about produced assets alongside estimates of their value in monetary terms, including the age and expected life of different asset types. Such information is commonly collated to support implementation of the perpetual inventory method (PIM) (see Chapter 17 for details). Ideally, estimates of expected asset lives and other forward-looking assumptions would incorporate information on the condition of the produced assets (for example from an engineering perspective), expected levels of use (for example in relation to population growth) and exposure to and relationships with catastrophic events (such as fire, flood, or earthquake). This additional information, alongside information recorded on other changes in the volume of assets and liabilities accounts (Chapter 13), could also be organized and presented to support analysis of sustainability.

## 2. The scope of natural capital

35.2335.24 *Natural capital refers to the sum of natural resources and ecosystem assets, of which the latter are not recognized as assets in the sequence of economic accounts.* The ~~System of Environmental Economic Accounting (SEEA)~~ provides the international standard to measure natural capital and has agreed concepts, definitions and accounting treatments for measuring the components of natural capital in physical and monetary terms, including approaches to recognizing benefits beyond the SNA production boundary. To establish a measurement scope for the stock of natural capital, SEEA defines environmental assets as *the naturally occurring living and non-living components of the Earth, together constituting the biophysical environment, which may provide benefits to humanity* (SEEA Central Framework, 2.17). ~~It is f~~From this broad, biophysical scope, that the two primary measurement categories emerge, i.e., ~~–~~ natural resources and ecosystem assets.

35.2435.25 *Natural resources are assets that naturally occur, such as land, water resources, timber and fish stocks, and mineral and energy resources that have an economic value and over which ownership may be enforced and transferred. Environmental assets over which ownership rights have not, or cannot, be*

*enforced, such as open seas or air, are excluded.* Natural resources are included in the SNA balance sheet ~~since when~~ they satisfy the SNA's definition of *economic* assets. The relevant types of natural resources include land, mineral and energy resources, biological resources (e.g. timber, fish, livestock), water resources and some other resources (e.g. radio spectra). Chapter 14 provides a complete set of definitions and descriptions of these natural resources from the perspective of the SNA asset boundary.

~~35.25~~35.26 *Ecosystem assets are contiguous spaces of a specific ecosystem type characterized by a distinct set of biotic and abiotic components and their interactions* (SEEA Ecosystem Accounting, 2.11). There are a wide range of types of ecosystem assets including forests, coral reefs, lakes, wetlands and urban areas where each occurrence of a specific type is treated as a distinct ecosystem asset. When accounting at a national level, all ecosystem assets within the economic territory of a country (including its exclusive economic zone (EEZ)) should be included such that the total area of the economic territory is accounted for.

~~35.26~~35.27 While this framing of natural capital encompasses stocks of natural resources and ecosystem assets, these two categories of natural capital are not mutually exclusive and there is a clear overlap between ecosystem assets and a number of natural resources including land, biological resources and water resources. For example, from the perspective of natural resources the stock of fish in a lake is a distinct asset while from the perspective of ecosystem assets the lake is a type of ecosystem and the fish stock is a feature or characteristic of that asset in addition to the water, plants and other animals in the lake. In effect, accounting for the stock of natural resources has a focus on individual components of the biophysical environment whereas accounting for the stock of ecosystem assets has a focus on the combination of individual components in distinct contexts.

~~35.27~~35.28 A further important point of difference between accounting for natural resources and accounting for ecosystem assets lies in the range of benefits which are within scope of measurement. For individual natural resources, for example timber resources, accounting *in monetary terms* in both the SNA and the SEEA is limited to recording the contributions of natural resources to benefits that are within scope of the SNA production boundary. For example, for timber resources, only the contribution of the trees to the *output of the forestry industry*~~production of timber~~ is recognized. In effect, for most natural resources other than land, this limits the accounting to recording those products that are harvested or extracted from the environment.

~~35.28~~35.29 In contrast, when accounting for ecosystem assets a wider measurement scope is applied that recognizes *ecosystem services, i.e.* the contributions of ecosystem assets (~~such as a forest~~), to benefits both within the SNA production boundary (such as timber) and outside the SNA production boundary, *recognizing that measurement the scope of measurement s may change over time as institutional contexts change, for example through the development of environmental markets or payments for ecosystem services schemes.* To facilitate this recording, *in ecosystem accounting* the contributions of ecosystem assets are separately recorded as flows of ecosystem services, whereas in the standard sequence of economic accounts the contributions of natural capital to SNA products are implicit in measures of gross operating surplus. The use of a broader scope of benefits and the explicit recording of ecosystem services permits the recognition of a range of contributions from natural capital, including among other things, air filtration services, flood mitigation services, coastal protection services, global climate regulation services, water purification services and recreation-related services. A more complete introduction to ecosystem accounting is provided in section C below.

~~35.29~~35.30 Overall, the combination of natural resources and ecosystem assets provides for the comprehensive measurement of the stock of natural capital. However, given the overlapping scope of these two components, careful partitioning of monetary values is required if there is a requirement for aggregation so that there is no double counting.

~~35.30~~35.31 Generally, individual elements and substances such as nitrogen, oxygen, carbon, soil nutrients, salt and phosphate that are present throughout the biophysical environment and commonly embodied in natural resources listed above are not treated as distinct assets. However, in some cases, and setting aside the individual elements (gold, copper, lithium) that are within the scope of mineral resources, specific deposits of other elements and substances that are harvested or mined can be treated as natural resources. This would include, for example, deposits of salt that are mined and extracted. Note that carbon embodied in trees and other biological resources may be recorded separately but is not considered a distinct asset.

~~35.31~~35.32 From the perspective of the SNA sequence of economic accounts, including the balance sheets, the

scope of natural capital excludes environmental assets over which ownership rights have not, or cannot, be established, such as open seas or the atmosphere. Further, stocks of natural capital are only recognized in the sequence of economic accounts to the extent that they provide economic benefits to their owners, either individually or collectively. In this context, economic benefits refer to gains arising from the economic activities of production, consumption or accumulation.

35.3235.33 Thus, for example, mineral and energy resources are included in the SNA balance sheet to the extent that they are commercially recoverable given current and expected technology and relative prices and potentially recoverable resources are excluded if it is not foreseen that they will be exploited in the near future. Similarly, water resources are included to the extent that their scarcity leads to the establishment of ownership and/or use rights, market valuation and some measure of economic control and biological resources are included to the extent that ownership rights are established which for migrating resources may be evidenced through a quota regime.

35.3335.34 As detailed further in section C below, the measurement scope of natural resources applied in the SEEA is broader than the SNA by including all resources irrespective of their current ownership status or provision of economic benefits. The only limit in the SEEA concerns the exclusion of those resources outside the economic territory over which a country has control, which for those countries with a maritime boundary will include its EEZ. On the other hand, it is also noted that in the SEEA the radio spectrum is not considered part of the biophysical environment and hence is not included as part of natural resources but, in the SNA, it is included as part of natural resources. Also, the SNA provides a more comprehensive accounting for renewable energy resources.

35.3435.35 A common topic of discussion in the measurement of natural capital is biodiversity. Following the Convention on Biological Diversity (CBD), *biodiversity is the variability among living organisms from all sources including, inter alia, terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are a part; this includes diversity within species, between species and of ecosystems*. In short, three levels of biodiversity are recognized – genetic diversity, species diversity and ecosystem diversity. From an accounting perspective, it is possible to organize data to support the derivation of measures of diversity at each of these levels, but diversity itself is not directly measured. For example, accounts can record the composition of different ecosystem types across a country and accounts can be used to record the mix of different species. Measurement of ecosystem assets will support the measurement of ecosystem diversity. SEEA Ecosystem Accounting provides a longer discussion on the links between accounting and the measurement of biodiversity.

### **3. The scope of human capital**

35.3535.36 A general definition of human capital is *the knowledge, skills, competencies and attributes embodied in individuals that facilitate the creation of personal, social and economic well-being*. This definition provides a clear foundation that incorporates both economic and non-economic benefits arising from the use of human capital by individuals. From an economic perspective, the creation of human capital, or put differently, the acquisition of knowledge, skills, competencies and attributes, increases the productive potential of the individuals in an economy and is a source of future economic benefit to them. In addition to knowledge and skills, the productive potential of individuals will be influenced by their health and life expectancy.

35.3635.37 In general, much of the focus from a national accounting perspective on human capital has been on the connection between human capital and labour inputs to production with the value of the stock of human capital being measured either in terms of future flows of labour earnings taking into account the current age and education profile and expected retirement ages or in terms of costs involved in generating human capital, e.g. education costs. The focus on the link to labour inputs to production supports standard macro-economic analysis, including productivity measurement.

35.3735.38 However, there are also important contributions of individuals' knowledge, skills, competencies and attributes to activities outside the SNA production boundary and extended measurement of human capital to recognize these contributions, for example in the areas of unpaid household service work, both to individual households and to wider society is encouraged. Consequently, a wider range of contributions can be recognized (i.e. beyond labour inputs to the production of goods and services within the SNA production

boundary) and also a wider range of individuals can be included in the stock of human capital (i.e. those people outside the labour force).

[35.3835.39](#) Section D provides a longer discussion on the measurement of human capital and the links to measurement of education and training are presented in Chapter 34. There is also relevant content in Chapter 16 on Labour [input](#) tables that presents a range of information on the composition and structure of the labour force which, in turn, supports understanding of the stock of human capital.

#### 4. The scope of social capital

[35.3935.40](#) The concept of social capital can be expressed in a number of different ways. For the purposes of discussion here ~~in broad terms, social capital refers to the social norms, shared values and institutional arrangements that foster co-operation within or among groups (OECD, 2001). to the combination of formal and informal institutions and networks that support the functioning of our societies and economies.~~ As noted in Chapter 2, measurement of social capital is a developing area but, at present, its measurement from an accounting perspective, in particular concerning its valuation, is not sufficiently advanced for a substantive discussion of ~~its~~ measurement approaches ~~to be included~~ here. Nonetheless, Section E provides an introduction to the concepts and measurement of social capital recognizing the need for research and discussion to establish the ways in which social capital can be effectively defined and measured for statistical and accounting purposes.

### C. Measuring natural capital using the SEEA

[35.41](#) As introduced in Section B.2, the SEEA [complements the SNA by providing](#) the statistical standards and accounting framework for the organization of data about natural capital and its connection to the economy. This provides the basis for measuring the wider scope of natural capital that is relevant for the analysis of sustainability. ~~A full description of relevant concepts, definitions, accounting rules, classifications and other content is provided in the SEEA Central Framework and the SEEA Ecosystem Accounting and in a number of related documents and guidance materials.~~

[35.40](#) This section provides a short overview of ~~that material~~ [the accounting described in the SEEA](#) and highlights distinctions between the treatments in the SEEA and those applied in the compilation of the SNA sequence of economic accounts. [The section is structured following the](#)

[35.4135.42](#) ~~This section summarizes~~ four broad [measurement-accounting](#) themes of the SEEA: ~~that are relevant to accounting for the various stocks and flows related to natural capital. They concern~~ (i) accounting for natural resources (excluding land); (ii) accounting for land and ecosystems; (iii) accounting for environmental flows; and (iv) accounting for [environmental activities and transactions \(e.g. environmental protection activity and environmental taxes\)](#) ~~responses to environmental challenges by economic units. A full description of relevant concepts, definitions, accounting rules, classifications and other content is provided in the SEEA Central Framework and the SEEA Ecosystem Accounting and in a number of related documents and guidance materials.~~

[35.4235.43](#) An initial motivation for the development of the SEEA was the desire to recognize explicitly the costs arising from economic activity of using, depleting, or degrading natural capital such that measures of economic growth, for example gross domestic product, could be adjusted and hence reflect more completely the implications and sustainability of patterns of economic growth. Over time, while this motivation has remained, the richness of the connections between the environment and the economy has become more fully understood and has driven the breadth of measurement themes listed above.

[35.4335.44](#) A key role of the SEEA is therefore to bring an increased level of consistency and coherence across each of these measurement themes using accounting-based approaches recognizing that, in general, measurement of the environment has been undertaken in a less structured and coordinated way compared to measurement of the economy. Three aspects of the application of accounting approaches in the SEEA are highlighted here. First, the SEEA develops accounts in both physical and monetary terms for both stocks and flows related to natural capital. This focus supports direct integration of the rich body of scientific research and data about the environment and ensures that measures in monetary terms can be grounded in an

appropriate biophysical reality.

~~35.44~~35.45 Second, the SEEA applies and adapts the accounting rules and treatments of the SNA with the intent of supporting the integration of environmental data with the standard economic data organized within the SNA sequence of economic accounts. This connection is present in the SEEA's articulation of production boundaries and asset boundaries, approaches to monetary valuation and the structure of accounts such as supply and use tables and asset accounts.

~~35.45~~35.46 Third, the SEEA uses standard classifications and typologies to build connections across the different accounts, including the SNA sequence of economic accounts. These classifications and typologies cover industries, institutional sectors, products, natural inputs, residuals, environmental assets, environmental purposes, ecosystem types and ecosystem services. These classifications and typologies also support building connections between the definitions and classifications used by the individual subject matter experts (e.g. energy and water experts) and the standard economic classifications with the objective of integrating existing subject matter specific data with economic data through a structured accounting approach.

~~35.46~~35.47 Overall, the SEEA aims to provide a rich description of natural capital and its links to the economy. This description emerges both through compiling accounts that provide a baseline of coherent data and through establishing a common language for economists, environmental scientists, accountants and statisticians to support the organization and exchange of data about the many components of natural capital and their links to the economy.

## 1. Accounting for natural resources

~~35.47~~35.48 Accounting for natural resources ~~in the SEEA~~ is described in the SEEA Central Framework. The aim is to compile comprehensive asset accounts in physical and monetary terms for individual natural resources. The SEEA describes asset accounts for both non-renewable and renewable natural resources including mineral and energy resources, soil resources, timber resources, aquatic resources (in particular fish stocks) and water resources. The purpose in developing these accounts is to organize data on the stocks and changes in stocks of each of the resources and hence support an understanding of whether the current patterns of extraction and harvest of resources is sustainable. ~~It should be noted that in these asset accounts, in situ uses of the resources are excluded.~~

~~35.48~~35.49 For an individual natural resource, an indicator of sustainability is depletion reflecting the decline in the quantity of a resource that is not offset by regeneration of the stock recognizing that the degree of regeneration will be dependent on the extent and condition of the underlying stock of the resource. Depletion can be measured for each resource in physical terms ~~for each resource~~ and in monetary terms by estimating prices for the value of the change in the stock (see SEEA Central Framework Annex 5.1). The SEEA Central Framework describes the accounting entries that are relevant for attributing the cost of depletion against the extractor of the resource and, following a similar motivation, the SNA sequence of economic accounts records depletion as a cost of production of the extractor following the split asset approach as described in Chapters 14 and 27.

~~35.49~~35.50 The natural resource asset accounts described in the SEEA follow the same structure as asset accounts in the SNA commencing with an entry for the opening stock at the beginning of the accounting period, showing entries for additions to stock and reductions in stock, including changes due to normal growth and extraction and changes due to catastrophic events, and concluding with an entry for the closing stock at the end of the accounting period. For the asset accounts in monetary terms a revaluation entry is also included.

~~35.50~~35.51 The monetary valuation of natural resource stocks and changes in stocks in the SEEA aligns with the SNA and the same valuation concept is applied. Thus, balance sheet values in monetary terms and measures of depletion in monetary terms are able to be used commonly in both accounting systems. From this perspective, the description of accounting for natural resources in the SEEA provides a richer and more comprehensive discussion than is provided in the SNA but one which can be used to support directly the compilation of estimates for the SNA sequence of economic accounts.

~~35.51~~35.52 The following table shows the entries that are most likely for different types of natural resources and provides a stylized overview of the information organized and presented concerning natural resources

using the SEEA. The focus of each asset account is on a single natural resource with the scope generally referring to the quantity of a resource within a country. The measurement of depletion in physical terms will generally focus on measurement of extraction but in the case of renewable resources the growth in stock will also be relevant. Reclassifications concern changes arising when a resource is used for a different purpose.

**Table 35.1: General structure of the asset accounts for natural resources**

	Mineral & energy resources	Land (incl. forest land)	Timber resources	Aquatic resources	Water resources
<b>Opening stock of resources</b>	Yes	Yes	Yes	Yes	Yes
<b>Additions to stock of resources</b>					
Growth in stock	na	Yes*	Growth	Growth	Precipitation Return flows
Discoveries of new stock	Yes	na	na	Yes*	Yes*
Upwards reappraisals	Yes	Yes	Yes*	Yes*	Yes*
Reclassifications	Yes	Yes	Yes	Yes	<del>na</del> Yes
<i>Total additions to stock</i>					
<b>Reductions in stock of resources</b>					
Extractions	Extractions	na	Removals	Gross catch	Abstraction
Normal reductions in stock	na	na	Natural losses	Normal losses	Evaporation Evapotranspiration
Catastrophic losses	Yes*	Yes*	Yes	Yes	Yes*
Downwards reappraisals	Yes	Yes	Yes*	Yes*	Yes*
Reclassifications	Yes	Yes	Yes	Yes	na
<i>Total reductions in stock</i>					
<b>Closing stock of resources</b>	Yes	Yes	Yes	Yes	Yes

na – not applicable

\* - An asterisk indicates that this flow is not usually a significant flow for the resource or it is typically not separately identified in the source data. In practice, not all cells that show the possibility of an entry here should be shown separately in the published accounts for each type of resource.

## 2. Accounting for land and ecosystems

~~35.52~~35.53 Accounting for land and ecosystems is described in both the SEEA Central Framework and the SEEA Ecosystem Accounting. The starting premise is that a geographic area, such as the total area of the economic territory of a country, can be fully delineated into different types of areas according to agreed concepts, definitions and classifications. This measurement scope is broader than that applied in the SNA sequence of economic accounts which only includes areas of land that satisfy the SNA's definition of an asset. Further the scope explicitly includes all inland waters and marine areas within a country's EEZ.

~~35.53~~35.54 Tracking the composition and changes in the composition of a country's land use, land cover and ecosystems can provide important information on the extent to which certain areas of a country are changing (e.g. due to urbanization), support measurement of changes in the condition of the environment, monitor the balance of ways in which land is used (e.g. for agriculture) and underpin analysis of future trends. In accounting for the area of land and ecosystems data can be presented in tabular form but it is also common and of significant analytical benefit, to present data in the form of maps which best supports spatial analysis. Spatial analysis is needed since, at a national scale, it is likely that the effects of important changes occurring at landscape scale are overlooked and the associated sustainability challenges are ignored.

~~35.54~~35.55 In accounting for land, the SEEA and the SNA have a different framing. including inland water and marine areas within a country's EEZ. Tthe SNA SEEA does not considers land as a type of natural resource alongside timber, fish and minerals as in the SNA and, as a consequence, incorporates any associated soil resources within land. Rather Tthe SEEA, on the other hand, has a distinct view that *land is a unique environmental asset that delineates the space in which economic activities and environmental processes take place and within which environmental assets and economic assets are located*. A consequence of this conceptualization is that land itself is non-depletable – i.e. the space cannot be reduced over time. However, the characteristics or attributes of that space can change and it is these characteristics that are the most common focus of accounting for natural capital. The changes in characteristics may be large, for example from terrestrial to marine ecosystems in the case of sea-level rise, or the reverse in the case of reclamation projects. This approach contrasts with the SNA framing in which the entry point is whether a particular area provides economic benefits.

~~35.55~~35.56 An important statistical outcome in conceptualizing land (including inland water and marine areas) as space, is that accounting for land then provides the foundation for ensuring a comprehensive measurement of all ecosystems and natural resources, in a similar way to that of a business register providing a comprehensive basis for the measurement of economic activity of a country.

~~35.56~~—The delineation of areas within a country can be undertaken using a range of concepts and methods. The two primary concepts for accounting for land are land use and land cover. Land use reflects both (a) the activities undertaken and (b) the institutional arrangements put in place for a given area for the purposes of economic production, or the maintenance and restoration of environmental functions (SEEA Central Framework 5.246). Examples of land uses include agriculture and forestry. Land cover refers to the observed physical and biological cover of the Earth's surface and includes natural vegetation and abiotic (non-living) surfaces. Examples of land cover include herbaceous crops, tree-covered areas and grassland. The SEEA Central Framework provides a full description of accounts for land use and land cover and the associated classifications. The SEEA Central Framework provides a description of accounts for land use and land cover and the associated classifications. Land accounts take the form of asset accounts with an opening area, additions and reductions in area and closing area. Land accounts may also be developed on the basis of land ownership or tenure, for example by industry or institutional sector, and monetary values for land can also be estimated. A powerful analytical tool is the land account change matrix showing, for a given concept such as land use or land cover, which classes of land have changed between two points in time. The table below shows a land cover change matrix.

35.58 **Table 35.2: Land cover change matrix (SEEA Central Framework)**

Land cover	Increases (positive numbers) and decreases (negative numbers) from other land covers												Net change (increase-decrease)
	Opening area	Artificial surfaces	Crops	Grassland	Tree covered area	Mangroves	Shrub covered area	Regularly flooded areas	Sparse natural vegetated areas	Terrestrial barren land	Permanent snow, glaciers and inland water bodies	Coastal water and inter-tidal areas	
Artificial surfaces													
Crops													
Grassland													
Tree covered area													
Mangroves													
Shrub covered area													
Regularly flooded areas													
Sparse natural vegetated areas													
Terrestrial barren land													
Permanent snow, glaciers and inland water bodies													
Coastal water and inter-tidal areas													

35.59 35.58 Accounting for ecosystems commences with the delineation of a country's area according to a classification of ecosystem types and ecosystem extent accounts, ~~which follow the structure of land accounts just described can be compiled.~~ These accounts show the composition of a geographic area referred to as an ecosystem accounting area (e.g. a country, province, catchment) in terms of different types of ecosystem assets, for example, the area of forests, wetlands, mangroves, lakes and urban areas, and how this composition is changing over time. The difference between ecosystem extent accounts and land accounts does not concern the account structure but the different classification of areas. In short, ecosystem extent accounts focus on summarizing the combined ecological characteristics of spatial areas (vegetation, climate, soil, etc) rather than a single characteristic such as land use or land cover. — i.e. the different classes of ecosystem types, land uses and land cover.

35.61 35.59 Other aspects of accounting for ecosystems build on the delineation of ecosystem assets to provide a structured and coherent data set on the condition of ecosystem assets, the ecosystem services generated by ecosystem assets in physical and monetary terms, the use of ecosystem services by different economic units, and the value of stocks and changes in stocks, including degradation, of ecosystem assets based on the net present value of the expected ecosystem service flows.

35.62 35.60 The core components of the ecosystem accounting framework ~~is-are~~ shown in Figure 35.2 ~~below~~ and Figure 35.3 shows the set of ecosystem accounts. SEEA Ecosystem Accounting provides a description of the concepts, definitions, classifications and accounting treatments. Collectively, the information set established through ecosystem accounting provides a basis for a wide range of analysis about the connection between natural capital and the economy including, for example, the potential to estimate a range of ~~market and non-market~~ effects of changes in ecosystems on different economic units. For example, the effects of excess flows of nitrogen into rivers on downstream users including water supply companies and those visiting for recreation.

Figure 35.2: The general ecosystem accounting framework (SEEA Ecosystem Accounting)

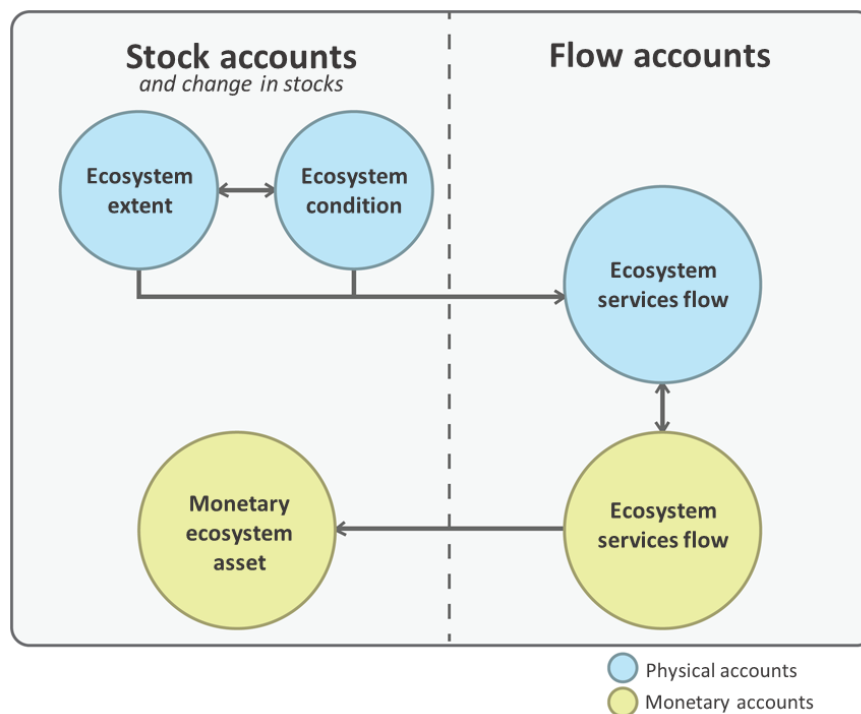

Figure 35.3: Connections between the ecosystem accounts (SEEA Ecosystem Accounting)

35.6335.61 For some types of land, in particular agricultural land, forest land and urban areas, all of which are

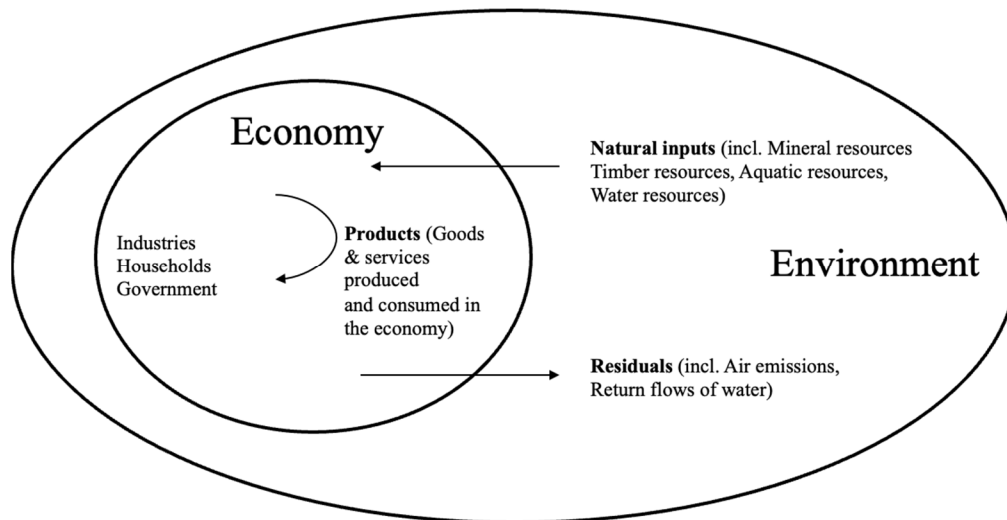

in scope of ecosystem accounting, there will be an overlap between the monetary value of ecosystem assets and the value of the land recorded in the SNA balance sheet. This overlap arises because the ecosystem services generated by those areas include some services which contribute to generate economic benefits for the owners of the land. For example, the value of agricultural land will be linked to the supply of crop provisioning services, ~~the value of forest land will be linked to the supply of wood provisioning services and the value of urban land will be linked to the supply of recreation related services (e.g. from urban parks).~~ Consequently, care needs to be taken in integrating measures of ecosystem asset values in monetary terms with the value of land and other assets in the SNA balance sheet. A discussion on this topic is presented in SEEA Ecosystem Accounting Chapter 11.

~~35.64~~35.62 The core ecosystem accounting framework can be applied in a range of different ways applying the general principles of thematic accounting as described in Chapter 38. This includes accounting for stocks of carbon, for species, for individual ecosystem types such as forests and marine areas, for specific land use types such as protected areas and for links between ecosystems and economic activities such as agriculture and tourism. ~~In the development of ecosystem accounting since 2010, the ecosystem accounting framework has been applied to more directly account for other components of natural capital including stocks and changes in stocks of carbon and species. Data from carbon stock accounts and species accounts provide valuable and policy relevant information in their own right but also support the compilation of the various ecosystem accounts. It has also proved relevant to focus ecosystem accounting work on specific ecosystem types, for example mangroves, forests, wetlands, urban areas and oceans, to provide a systematic view of the links between those ecosystem types and economic activity. Other ecosystem accounting work has looked at connections between ecosystems and selected economic activities such as tourism and agriculture, or for specific land use types such as protected areas. Overall, the core ecosystem accounting framework can be applied in a range of different ways applying the general principles of thematic accounting as described in Chapter 38.~~

### 3. Accounting for environmental flows

35.63 A fundamental component in the SEEA is the description of standard approaches to the recording of data about environmental flows. Environmental flows concern flows of substances such as water, energy, solid waste, air emissions, that move from the environment to the economy (natural inputs), within the economy or from the economy to the environment (residuals) (see Figure 35.4). The tracking of environmental flows using PSUT supports direct connection to production and consumption data in the standard monetary SUT accounts and more generally, provides insight into the pressures and impacts on the environment from different industries and how this is changing over time. The information can be readily linked to measuring the success of progress toward a more circular economy, a common focus of sustainability policies. Further, these accounts are essential for building footprint indicators that reflect the quantity of carbon, energy, materials, water and emissions embedded in products being consumed domestically or traded internationally. ~~The accounting is undertaken in physical terms for each substance using a supply and use structure with the environment being included as an additional supplier and user.~~

**Figure 35.4: Flows between the economy and the environment (SEEA Central Framework)**

35.65 35.64 The A-accounting for environmental flows is undertaken in physical terms for each substance using a supply and use structure with the environment being included as an additional supplier and user. The physical supply and use tables (PSUT) that are used to record environmental flows provide a rich information set linking the flows of each substance to extracting or generating industries. For example, the energy PSUT organizes data on flows of energy from different natural inputs (coal, oil, gas, biomass) to economic units and through the economy; and the air emissions PSUT organizes data on the flows of air pollutants generated by different industries.

~~35.66 The tracking of environmental flows using PSUT supports direct connection to production and consumption data in the standard monetary SUT and more generally, provides insight into the pressures and impacts on the environment from different industries and how this is changing over time. The information can be readily linked to measuring the success of progress toward a more circular economy, a common focus of sustainability policies. Further, these accounts are essential for building footprint indicators that reflect the quantity of carbon, energy, materials, water and emissions embedded in products being consumed domestically or traded internationally.~~

35.67 35.65 Generally, PSUT are compiled at national level but where they can be compiled at a sub-national scale (for example, water PSUT compiled by catchment) the variation in environmental pressures and impacts across the country can be identified and, ideally, linked to data from the ecosystem accounting on the changing condition of ecosystem assets. For example, data on the condition of rivers might be linked to data from the water PSUT on abstraction of water and generation of wastewater. PSUT are usually compiled on an annual frequency but higher frequencies can also be compiled. For example, quarterly air emission accounts can be compiled and released side by side with quarterly estimates of GDP to track progress towards a low carbon economy.

35.68 35.66 In addition to these flows of natural inputs, products and residuals, flows of ecosystem services can be recorded in supply and use tables in both physical and monetary terms. These tables show the supply of ecosystem services by different types of ecosystem assets and the use of ecosystem services by economic units. The SEEA EA provides a reference list of ecosystem services covering provisioning services, regulating and maintenance services and cultural services.

#### 4. Accounting for environmental activities and transactions

35.67 The three accounting ~~components~~ themes discussed above (i.e. natural resources, land and ecosystems and environmental flows) focus on recording different natural capital stocks and flows. The fourth ~~component~~ accounting theme focuses on identifying transactions, such as environmental taxes and environmental protection expenditure, that are recorded in the SNA's sequence of economic accounts ~~that and which~~ relate to natural capital. These data are of high relevance in the discussion of environmental sustainability since they provide insight into the responses of economic units to environmental challenges. Many of the

transactions concern government activity and regulation concerning natural capital but there is also the potential to record the activities of businesses and households as they relate to production and expenditure for environmental purposes. Across all sectors there is an increased level of economic activity for these purposes and the use of standard frameworks and definitions to record the relevant transactions, including cross-border flows, is of significant policy and analytical interest, for example in relation to managing responses to climate change.

~~35.69~~35.68 The SEEA Central Framework describes the range of transactions along with relevant definitions, accounting treatments and classifications. ~~There are a number of~~ types of transactions that are within scope are:

- Environmental taxes
- Environmental subsidies and similar transfers
- Transactions related to environmental protection and resource management
- Transactions related to the environmental goods and services sector
- Transactions related to the use of natural resources including permits, licences and rents

~~35.70~~ Each of these types of transactions is described in the SEEA Central Framework along with relevant definitions, accounting treatments and classifications.

~~35.71~~ These data are of high relevance in the discussion of environmental sustainability since they provide insight into the responses of economic units to environmental challenges. Many of the transactions concern government activity and regulation concerning natural capital but there is also the potential to record the activities of businesses and households as they relate to production and expenditure for environmental purposes. Across all sectors there is an increased level of economic activity for these purposes and the use of standard frameworks and definitions to record the relevant transactions, including cross border flows, is of significant policy and analytical interest, for example in relation to managing responses to climate change.

~~35.72~~35.69 While conceptually all of these transactions are within scope of the SNA, in practice, the major challenges are identifying the relevant transactions, especially in terms of whether a particular transaction has a primary purpose which is environmental, and consistently classifying the transactions to support comparability over time and across countries. The challenge of identification is heightened in the common situation where the economic unit involved has a primary activity that is not environmentally related. The Classification of Environmental Purposes (UN, 2024) provides adopted in 2024 support to compilers in identifying and consistently recording the relevant transactions. Note that some of these transactions may be identifiable in other classifications such as COFOG Division 5 – Environmental Protection. provides a framework for classifying a wide range of relevant transactions.

~~35.73~~35.70 To support a more structured approach to recording transactions for environmental purposes, the SEEA Central Framework describes environmental protection expenditure accounts (EPEA) which provide a series of tables for recording the supply of environmental protection production-specific services, the national expenditure on environmental protection and the financing of that expenditure. The SEEA Central Framework also describes a table for the presentation of data on the environmental goods and services sector (EGSS) covering the output of environmental goods and services and associated measures of intermediate consumption, gross value added, compensation-remuneration of employees, gross fixed capital formation, exports and employment.

## D. Measuring human capital

~~35.74~~35.71 A general definition of Hhuman capital refers to is “the knowledge, skills, competencies and attributes embodied in individuals that facilitate the creation of personal, social and economic well-being (OECD, 2001).”<sup>‡</sup> This definition provides a clear foundation that incorporates both economic and non-economic benefits arising from the use of human capital by individuals. From an economic perspective, the

---

<sup>‡</sup>-OECD, 2001

creation of human capital, or put differently, the acquisition of knowledge, skills, competencies and attributes, increases the productive potential of the individuals in an economy and is a source of future economic benefit to them. Critical inputs to the creation of human capital are education and training but the consumption of these inputs is not sufficient. In addition, creating human capital requires the assembly and processing of these inputs by the individuals consuming them with the result that each individual creates a unique set of capabilities.

35.72 From an SNA perspective, there has been a long-standing discussion on the potential to capitalize education and training expenditures within the sequence of economic accounts and recognize human capital as an economic asset on the balance sheet. Thus, although human capital has not been included in the sequence of economic accounts, the discussion here is of high relevance for extending and broadening the sequence of economic accounts. The reasons for human capital's exclusion from the sequence of economic accounts are presented later in this section.

35.7535.73 This section provides a description of ways in which the sequence of economic accounts can be connected to additional data on human capital with a strong focus on the conceptual aspects. At the same time, although not described here, there is a substantive body of empirical work that has also been conducted over many years that underpins the conceptual development and demonstrates the feasibility of measurement of human capital. One lesson from this empirical work is that due to data availability measurement of human capital is usually limited to a focus on the working-age population in formal employment and undertaking work within the SNA production boundary.

35.7635.74 Considering human capital as an economic asset leads to two approaches by which human capital may be valued in monetary terms. The first approach is a cost-based approach which sums the costs of generating human capital, principally expenditures on costs to supply education and training services. To apply this approach, the extended accounts for education and training described in the next section organize the relevant input data. The second approach is the lifetime labour earnings approach which estimates the value of human capital by calculating the net present value of future earnings of individuals within an economy. Both of these approaches inherently have a focus on the economic benefits arising from human capital, i.e. the contribution of labour to production within the SNA production boundary. While not elaborated here, a broader focus is possible incorporating the contributions of human capital to unpaid household service work, including volunteering, and the non-economic individual and societal benefits of human capital, e.g. in terms of civic engagement and participation.

35.75 The UNECE Guide on Measuring Human Capital (2016) provides a thorough description of these two approaches and the discussion here summarizes the key aspects. From a theoretical point of view, the net present value based approach is the most appropriate, as it incorporates all future economic benefits that can be allocated to the relevant asset, thus replicating a market-equivalent valuation. However, its measurement requires a number of assumptions on the future development of the (active) population and the future pattern of economic benefits. The total values can also be significantly affected by the discount rate that is applied.

35.7735.76 To complement estimates from the net present value approach, a cost-based approach can be applied using the perpetual inventory method (PIM). In this approach, the investment costs for creating human capital are summed to obtain an estimate of the value of the human capital. These costs do not only relate to formal education, but also include training and courses provided by employers; time spent on learning and studying at home; and other expenditures on, for example, school books and other training material. This method approach also requires several assumptions, for example on the distinction between expenditures that are current in nature (e.g. running and maintenance costs) and expenditures which add to the stock of human capital. Also, assumptions are needed and to measure and to value any unpaid activities and concerning the service lives and the depreciation pattern of human capital. Measurement must also consider methods for measuring and valuing inputs from unpaid household service activities (e.g. concerning childcare), for dealing with flows of migrants, and for determining appropriate products and price indexes for the derivation of volume measures. In practice, both approaches yield different results and further understanding of the differences is required.

35.7835.77 Table 35.2 provides a structure for presenting data on human capital and related variables.

**Table 35.2 Summary human capital table**

		Employment	Hours worked	Remuneration	Human capital -	Human capital -
		by ISIC	by ISIC	of employees	Lifetime labour	Cost-based PIM
		Number people employed	Hours	Monetary	earnings	by ISIC
Total					Monetary	Monetary
By individual characteristic						
	Age					
	Sex					
	Education status					

35.7935.78 In applying both approaches there are a number of measurement challenges described below which must be considered by compilers.

- The development of human capital takes place over a long but varying length of time, indeed, potentially over a life time, which complicates the determination of the timing of investment (and the contribution of individual years).
- The development of human capital relates to the input of education and training provided by other economic units but will also be built through personal experiences and unpaid inputs (unpaid household service work) of family and friends.
- The use of human capital in production is limited by the amount of time that a person provides labour input but the precise pattern of that use varies over time and hence the way in which human capital depreciates needs to be considered. The variation in the pattern of use will also affect the determination of asset lives.
- Human capital may be considered not as a single product but as a combination of skills and knowledge about different topics and each of these may have different development and use profiles and asset lives.
- Depending on wider economic and social conditions, certain skills and knowledge may become obsolete from an economic perspective, for example through changes in technology.
- There is a very large heterogeneity in individual's combination of skills and experience and how these align to particular occupations and industries.
- The quality of educational experiences and the impact of education on the development of human capital varies across individuals and may not be directly related to the volume or cost of education.
- There are additional benefits (known as spillover effects) when knowledge and experience is shared among employees in a work place and more broadly through society, which in turn challenges the ability to use the sum of measures of human capital of individuals to reflect the aggregate contribution of human capital.

35.8035.79 Given t~~These challenges~~-are real but also exist for many assets within scope of the SNA sequence of accounts. T~~he~~ primary issue for compilation is therefore the extent to which appropriate assumptions can

be determined to provide reasonable estimates of human capital to support discussion and analysis. In this context, while the focus of discussion here is on the estimation of a monetary value of human capital, it is essential to collect a substantial range of non-monetary data to support measurement and the testing of assumptions. Relevant non-monetary data include data on years of education, the number of people in different professions, and the levels of skills and experience. In that regard, accounting for human capital provides a framework for the organization of an array of data building on the labour tables (Chapter 16) and the extended accounts for education and training described below.

35.81 35.80 While there are challenges in the measurement of human capital and ongoing research is encouraged, these practical concerns are not the primary reason for exclusion of human capital from the SNA sequence of economic accounts. One long-standing conceptual concern is that although the treatment of expenditure on education and training as analogous to gross fixed capital formation is possible, the nature of the acquisition of the benefits of education and training is such that they are activities that cannot be undertaken by anyone else on behalf of the student. Thus, the acquisition of knowledge is not a process of production in and of itself, even though the instruction conveyed by education services is. The consequence is that human capital cannot be considered produced. The more recent investigation into knowledge products and the capitalization of intangibles such as marketing assets suggests that this concern about whether human capital can be produced merits further investigation.

35.82 35.81 Another conceptual concern has been the question of ownership rights and the extent to which human capital is capable of bringing economic benefits to its owner, as required to satisfy the definition of economic assets. Since ownership is often connected with expenditures, such a framing may be evident in the situation where firms undertake expenditure to train and develop the skills of their employees. In which case the firms will be the owners of the human capital that is created since they will be accruing the associated economic benefits. Unfortunately, this framing concern connects the question of ownership of human capital to the problematic idea that people are “owned”. ~~However, an~~ alternative framing is that human capital is embodied in individuals who in effect own their skills, knowledge and experience and utilize these capabilities to secure future economic benefits for themselves. Again, there is merit in further investigation of these different perspectives, recognizing as well that the accounting implications of each perspective are varied.

35.83 35.82 Notwithstanding these specific conceptual concerns, it must be recognized that establishing human capital as an asset within the sequence of economic accounts would have substantial implications for the structure of the accounts and the interpretation of traditional measures of consumption, income, investment and saving, especially for the household sector but also more broadly. Resolving these implications requires determining the appropriate accounting entries to show that those paying for the development of human capital (e.g. governments, corporations) transfer the accumulation of benefits to the individuals whose human capital is enhanced. In part this may involve consideration of social transfers in kind related to education. The interpretation of remuneration of employees also needs consideration since in a human capital framing this flow ~~could be would~~ represented as a payment for capital services to the owner of the human capital. While accounting solutions to these types of changes have been developed (see UNECE 2016), a wider discussion is required of the potential changes to the sequence of economic accounts and the implications for key economic measures and their interpretation ~~is required~~.

35.84 35.83 Finally, the measurement of human capital allows for connection to a range of other topics that are important for individual human capital accumulation. These include health, parental and family engagement, cultural and social engagement and wider work-related human capital accumulation beyond in-work training.

35.85 35.84 Health is a key aspect of an individual's human capital. This includes, for example, the effect of the lack of various diseases, illnesses and disabilities providing a higher level of physical and cognitive skills directly, as well as enabling further development into the future. Conversely, lack of good health can be seen as an impairment of an individual's opportunity to develop, while also having a detrimental impact on an individual's human capital today. Better health can also support the longer use of an individual's human capital, whether in the marketplace or in wider economic activity.

35.86 35.85 Similarly, people's family situation, and the cultural and social activities people engage in both as children and adults (e.g. attending museums, participating in social clubs, undertaking personal projects) are known to influence people's cognitive, physical, social and emotional development. While all of these factors will influence the development of people's human capital, the mechanisms by which this occurs is an area of

active research (e.g. determining the relative role of parental income versus the opportunities such income provides). In addition, incorporating these issues within either an income-based or cost-based approach requires further discussion both in terms of valuation concepts and regarding data sources to support international comparability.

~~35.87~~35.86 Lastly, beyond the wider social aspects feeding into human capital investment, it is known that there are other mechanisms that influence a person's development in the workplace. In particular, support networks, mentorship opportunities, and the quality and quantity of feedback on a person's work allow them to improve their skills and knowledge, and hence their potential human capital. There are also aspects of the extent to which employees are encouraged and extended in their work, while also being supported, so that they are able to improve their marginal productivity. All of these concepts are clearly important in the aggregate, but due to measurement issues, such as how to convert such opportunities above as intangible 'investment' when there is no market transaction, and what the imputed transaction may need to be, mean this is still an active research area.

~~35.88~~35.87 Collectively, all of the topics introduced in the paragraphs above describe a large research agenda. Thus, notwithstanding the significant progress on accounting for human capital that provides a strong foundation for measurement, there remain many areas in which additional investigation and testing should be undertaken to more fully harmonize and integrate the accounting required for the development and contribution of people's knowledge, skills and experience.

## E. Measuring social capital

~~35.89~~35.88 The concept of social capital ~~can be understood and is~~ expressed in a number of different ways ~~and applying different theoretical perspectives.~~ *For the purposes of discussion here, social capital refers to ~~Most broadly, it is about~~ the social norms, shared values and institutional arrangements that foster co-operation among population groups (OECD, 2001).* Given the variety of norms, values and institutional arrangements, it is not surprising that social capital can be measured in a range of ways and researchers have highlighted social capital's influence at the level of individuals, at the level of social networks and at the level of institutions. ~~For the purposes of discussion here, social capital is defined as the combination of formal and informal institutions and networks that support the functioning of our societies and economies.~~

~~35.90~~35.89 Drawing from the research ~~on~~ by the Conference of European Statisticians (CES) on measuring sustainable development (UNECE, 2015), social capital can influence well-being through three primary channels:

- i. Direct well-being effects on individuals who are part of social networks. From a well-being perspective, it is important to include in the measurement of social capital those networks that aim to connect different groups in society as these networks can be expected to generate high levels of generalized trust and may have the highest impact on the well-being of society as a whole. Through this channel there will be close connections to the role of human capital and delineating the contributions of each capital will be important for accounting purposes.
- ii. Stimulation of increases in other types of capital. This may occur for example in the context of human capital where social networks facilitate job searches and reduce unemployment or in the context of education where supportive parents and communities can drive better education outcomes for students. In the context of economic capital, social networks can support innovation and the general creation and diffusion of knowledge. In the context of natural capital, social networks can build and change social norms and values with respect to the environment and the restoration of stocks of natural capital.
- iii. Through networks, increases in social capital can improve efficiency in the use of other capitals and in production processes generally and hence can support reductions in transaction costs. This effect will be driven not only through the number of networks but also by the levels of trust that are built up within networks. Higher levels of generalized trust can provide informal checks on processes and transactions and facilitate higher levels of social and economic interaction. At a macro-scale this effect can be seen in terms of the extent to which there are harmonious relationships between state and society.

35.9135.90 ~~Currently, recommendations on the measurement of s~~Social capital ~~are mainly focused on generating indicators expressed is almost exclusively measured~~ in physical units. The CES recommends five indicators two concerning the theme of trust – generalized trust and bridging social capital; and three concerning the theme of institutions – voter turnout, the percentage of women in parliament and the contribution to international institutions. Research in a range of contexts is ongoing to further develop metrics in this area and the integration of this research within a general multiple capitals framing is important given the range of connections across the capitals that are evident. In many contexts, it may be that investments in social capital provide a cost-effective means of securing well-being outcomes via its influence on the condition of the stocks of other capitals.

35.9235.91 ~~Techniques to express the value of The monetization of~~ social capital ~~in monetary terms have not yet been widely developed-seems to be out of reach for the foreseeable future~~ and consideration is needed as to whether this is a required objective. Recognizing that the assessment of sustainability requires a strong basis in data on the quantity and condition of capital stocks, a relevant near-term measurement objective is likely to involve a focus on physical measures and establishing agreed definitions and interpretations of social capital within the official statistical community as well as the wider sustainability and well-being community.

## F. Considerations in measuring sustainability

35.9335.92 The measurement of the different types of capital and all of the more detailed components is a significant undertaking. The SNA provides key definitions and treatments for all types of economic capital and some components of natural capital but for compilation purposes, additional guidance must be consulted and a range of handbooks and other materials have been prepared to provide this support. These include guidance on the measurement of the capital stock (of produced assets) (OECD, 2009), and guidance on the measurement of land (OECD & Eurostat, 2015). With respect to natural capital there are many SEEA based compilation resources, handbooks for individual natural resources such as timber, fish and mineral and energy resources, and implementation guidance on the measurement of natural resources within the context of the SNA sequence of economic accounts.

35.9435.93 This section highlights a small number of general measurement considerations that can arise in the measurement of stocks and flows of capitals ~~and in interpreting the resulting data~~. A general message is that all measures of capitals should be well documented to explain clearly the measurement scope and all relevant assumptions. These considerations are relevant in relation to measurement of the SNA sequence of economic accounts and to measurement of capitals beyond the sequence of economic accounts. ~~As well~~With this scope ~~in mind~~, the discussion in the following sections aims to highlight ~~the range of opportunities, and connections and contributions that -relevant to-~~national accounts compilers ~~can make to in-~~the ~~assessment measurement~~ of sustainability more generally.

### 1. Links to measurement of adjusted economic aggregates and extended accounts

35.9535.94 ~~As elaborated in Chapter 2, t~~The SNA sequence of economic accounts incorporates a range of net measures which adjust for the costs of depreciating and depleting economic and natural capital. These net measures include ~~net domestic product~~NDP, net national income and net household saving. Further, monetary values in balance sheets are recorded at their depreciated or depleted values, i.e. in net terms. ~~The concepts of depreciation and depletion can also be applied to capitals outside the scope of the sequence of economic accounts and hence i~~It is possible to extend the scope of net measures ~~to recognize other costs of capital and present these adjustments in extended, both in the income accounts and in the balance sheets, to incorporate a broader range of capitals.~~ The economic theory for the ~~these~~ extensions is developed in the literature on wealth accounting and estimates of ~~national wealth and indicators that adjust for the various costs of capital inclusive and comprehensive wealth~~based on this theory ~~are have been~~regularly published, ~~for example including~~by the World Bank and ~~the United Nations Environment Program (see Chapter 2, Box 1).~~UNEP, recognizing that these estimates do not cover all capitals and associated benefits.

35.9635.95 The SEEA Ecosystem Accounting, Chapter 11, describes the potential to extend the sequence of economic accounts based on monetary values of ecosystem services (thus extending the SNA production boundary) and associated monetary values of ecosystem assets and changes in the value of those assets

reflected in measures of enhancement and degradation. There are a number of challenges in ~~making this extension~~ undertaking monetary valuation of ecosystem services and assets, including aligning the values of ecosystem assets with the value of land as an economic asset and determining an appropriate allocation of values to institutional sectors in cases where the beneficiaries are not the ~~economic owners~~ or managers of an ecosystem, for example where the benefits of water purification services supplied by forest ecosystems benefit many households living downstream. These challenges are considered further in sections F.2 and F.4.

~~35.97~~35.96 A separate accounting application related to the measurement of environmental flows is the compilation of input-output tables which incorporate additional rows alongside the standard set of products. The additional rows, which concern things like water use, energy use, greenhouse gas~~GHG~~ emissions, material flows and ecosystem services, may be recorded in monetary or physical terms. These environmentally extended input-output tables are likely to be of significant relevance in the development of extended economic models aimed at assessing the implications of alternative climate and nature related policies. SEEA Applications and Extensions provides an introduction to environmentally extended input-output tables.

## 2. Valuation of natural capital

~~35.98~~35.97 The measurement of economic assets in the context of the SNA balance sheet has a focus on monetary valuation of the relevant stocks. For this purpose, the SNA has established relevant valuation concepts and principles that are described in Chapter 4. For the measurement of those assets that do not have an observed market price at the balance sheet date, the SNA proposes two measurement approaches (i) written down replacement cost (often estimated using the perpetual inventory method (PIM)) and (ii) net present value of future benefits. The first approach is commonly used in estimating the values of produced assets where the purchase price is observed but the current market value of the asset is not, while the second approach is most commonly used in estimating the monetary values of natural resources.

~~35.99~~35.98 To estimate monetary values for those capitals outside the sequence of economic accounts, a range of methods and valuation concepts have been applied. The internationally recognized statistical principles and recommendations for monetary valuation described approach outlined in Chapters 8-11 of the SEEA Ecosystem Accounting ~~use~~applies the same value concept – exchange values – as used in the SNA balance sheet to support the potential of extending the SNA balance sheet to incorporate the values of ecosystem services. The use of the exchange value concept supports the measurement of levels as required for national accounting and inherently incorporates both price and quantity components. In turn this supports the measurement of changes in volume and measurement in real terms as needed for the assessment of sustainability as discussed in the introduction to the chapter.

~~35.100~~35.99 In a similar way to the valuation of natural resources, the valuation of ecosystem assets is undertaken using the net present value approach based on expected future flows of ecosystem services estimated at their exchange values. SEEA Ecosystem Accounting Chapters 8-10 provides a discussion on a range of considerations concerning the implementation of this valuation approach.

~~35.101~~35.100 While the approach outlined in the SEEA Ecosystem Accounting does provide monetary values for natural capital beyond the SNA balance sheet, the values do not capture the full range of ecosystem services and related ~~all of the possible~~ benefits that may be attributed to ecosystems and, more broadly, any monetary value of natural capital will not reflect the complete set of values that can be attributed to natural capital. It is beyond the scope of this chapter to provide a complete discussion of this issue but the following points are highlighted. SEEA Ecosystem Accounting Section 2.4 provides a longer discussion of these issues.

35.101 First, in applying the concept of exchange value, the SNA and the SEEA, limit the scope of measurement to what are commonly called “use” or “instrumental” values, i.e. those values derived by people and economic units from natural capital through the direct or indirect use of natural capital in production or consumption, noting that use does not necessarily imply extraction of goods from the environment.

35.102 Second, in the economic valuation of natural capital, many economists also consider the role of non-use values which people associate with natural capital. Non-use values are commonly separated into two main types: (i) existence values where the value is based on knowledge that the ecosystem is present now; and (ii) bequest values where the value is based on making sure that the ecosystem is available to future generations.

Also recognized in some cases are option values that concern the potential for an ecosystem to provide use values in the future.

- 35.103 ~~Third, Second, beyond~~concerning non-economic values, other research on the value of natural capital has considered ~~relational values and~~intrinsic values (*i.e. values that are inherent to the asset and independent of any human experience or evaluation*) and relational values (*i.e. values that are relative to the meaningfulness of relationships between individuals and the environment*). Both of these types of value are likely to be relevant considerations in decision making but cannot be measured directly in monetary terms. However, they may be observed indirectly, for example, a person with high intrinsic value for an ecosystem might donate or may spend time volunteering with conservation organizations. Overall, the organization of data concerning the extent and condition of ecosystems and data on related expenditure or time-use can support the assessment of these non-economic values.
- 35.104 ~~Fourth-Third~~, it should be recognized that for any given stock of natural capital, it is most likely that different stakeholders will hold different combinations of the values just described – i.e. there are multiple value perspectives. Some of these perspectives may be able to be expressed in monetary terms but, as just noted, some may not. In this context, the role of statistics and accounting is not to provide a single measure or value but to organize a coherent set of complementary information that allows decision making processes to function as efficiently as possible.

### 3. Weak and strong sustainability

- 35.105 A focus on the measurement of the stocks of capitals can support different perspectives and interpretations of sustainability. As noted in the introduction, in economic theory, the sustainability of past developments is implied if the level of wealth in real terms is non-declining. Ideally, the measurement of past trends in wealth would be calculated at a relatively detailed level for specific asset types (i.e. below the level of economic, natural, human and social capital). Since it is expected that the relative prices of each asset type would change over time, it is expected that there will be substitution between asset types that would then be revealed in the measurements in both physical and monetary terms. Based on these trends in substitution and other information, such as limits on the availability of stocks of each asset type, projections may be made about future flows of benefits from the stocks as part of assessment about future prospects for sustainability and well-being.
- 35.106 In this framing, the concept of weak sustainability, assumes a situation where all types of capital (and all asset types) are perfect substitutes, a situation which is highly unlikely to occur. Importantly, the measurement of relative prices and changes in real wealth does not need to make an assumption of weak sustainability a priori. Conversely, the concept of strong sustainability assumes that no substitution is appropriate, again this is a situation which is unlikely to be revealed in measurement of past trends. However, in making projection about future trends, it may be of interest to identify specific types of capital which should not be lost. With respect to natural capital, the concept of critical natural capital (Ekins, 1997) has been used to this end, *i.e. identifying those stocks of natural capital on which society has a critical level of dependence*. The development of projections for real wealth based on maintaining certain capital stocks and comparing these projections to the subsequent trends may be of significant policy and analytical interest.

### 4. Aligning benefits and ownership

- 35.107 In defining assets, the SNA makes a direct link between economic ownership, including collective ownership, and the future benefits that are attributable to that asset. Consistently, costs associated with the use of an asset, including its depreciation or depletion, are attributed to the economic owner (or owners in the case of applying the split-asset approach where the benefits from a single resource are shared (see Chapter 27)).
- 35.108 This standard national accounting approach provides a complete structure for the organization of relevant information. It can also be extended to incorporate additional types of assets (such as ecosystem assets and human capital) and additional benefit flows (such as non-market ecosystem services). However, for some types of economic analysis, the allocation-attribution of benefits and costs only to economic owners is not appropriate and alternative presentations of data are relevant. Two particular examples highlight the potential

for alternative ~~economic framings~~ presentations. First, consider the supply of public goods by public infrastructure (such as roads) to transport firms and households. ~~In this case or the supply of recreation-related services to visitors by national parks. Both cases demonstrate that the~~ economic benefits from ~~the infrastructure do not a range of assets do not necessarily only~~ accrue to economic owners ~~of those assets, which is~~ generally general government. (Note that the SNA does support distinguishing between individual and collective consumption of households that can support analysis of ~~public goods~~ individual services purchased by government and supplied to households.)

- 35.109 Second, ~~the stock of some assets many assets~~ may decline ~~in quality in value~~ and have reduced capacity to supply services for reasons other than use in production by an economic owner. For example, water bodies used for ~~recreation or~~ water supply may be degraded as a result of excess nitrogen use in agricultural activities; and human health may be damaged by air pollution thus reducing the productivity of human capital. Consequently, there is a loss of benefit ~~(or increased costs)~~ to the economic owner that is not related to the use of the asset by ~~the~~ owner, ~~but due to the activity of another economic unit.~~
- 35.110 In both of these examples, there is often interest in developing alternative allocations and presentations of the flows of benefits and the costs of degradation or capital loss such that the economic connection of different economic units to the assets is revealed. For example, in the second example, the loss of benefit to the ~~economic owner~~ water supply company from damage to the water body might be attributed as a cost of production of the agricultural activity whose excess use of nitrogen is causing the damage. This general area of economic analysis concerns the assessment ~~of positive and negative~~ externalities. Discussion on the links between accounting and the analysis of externalities is presented in Chapter 2 ~~and 4~~, and in SEEA Ecosystem Accounting Chapter 12.
- 35.111 Although standard accounting-based approaches do not provide a presentation that reflects these alternative presentations, the data organized using accounting structures, especially when it is extended to capture a more complete set of data on multiple capitals and non-market benefits, provides a well-structured information set to support such analysis. Further, externality analysis will require a baseline set of information and also a counterfactual or alternative scenario for the purposes of comparison. As for the assessment of sustainability just noted above, accounting-based approaches can provide the baseline information set for use across multiple analyses.
- 35.112 It may well be the case that the requirements for the analysis of externalities is more local or project specific in nature in which case a set of national accounts may be too coarse but, in theory, the same accounting rules can be applied at all levels of granularity subject to the availability of data and resources.

## 5. Links to the assessment of capacity, resilience and risk

- 35.113 The assessment of sustainability is often discussed in the context of other systems related concepts such as capacity, resilience and risk, ~~which can all be linked to the discussion of ensuring well-being is sustained in the future.~~ The assessment of all of these concepts is related in the sense that they require consideration of the future and the projection of potential changes ~~to the stocks of capital.~~ Most assessments rely on using a baseline set of information about past trends and current levels of relevant stocks and flows. With a baseline in place, alternative scenarios and projections involving different assumptions can be made to complete assessments of sustainability, capacity, resilience and risk.
- 35.114 Accounting-based approaches that bring together information in a structured way and which cover multiple capitals provide an excellent structure for the required baseline information. Indeed, the use of a common baseline across different assessments can enhance the usefulness of assessments for decision makers since the differences across assessments can be more readily compared. This use of accounting-based approaches has been common practice in economic and financial modelling for many decades but its application in sustainability and related discussions has not ~~(yet)~~ been well-developed or widely adopted.
- 35.115 In addition to providing baseline information, accounting-based approaches support the use of a common framing for the formulation of alternative scenarios and assumptions. In particular, the use of a capitals framing facilitates organization of complementary data on relevant thresholds for the stocks of capitals, for example data on relevant biophysical limits (e.g. with respect to water quality) can be presented alongside accounting information on the current condition of ecosystem assets. In this example this complementary

data would allow identification of those ecosystem assets that are close to physical limits.

- 35.116 With respect to the assessment of risk in particular, a common starting point is understanding physical risks, for example due to the effects of climate change on agricultural production. From this starting point, the assessment of associated financial risks to companies and to the wider economy can be evaluated. The use of accounting-based approaches that present both physical and monetary data and that are designed to integrate with standard economic data and models can provide a robust basis for these assessments. In particular, accounting-based approaches can be ~~adapted and~~ applied at local and landscape scales on a consistent basis thus allowing context specific information to be utilized which will generally be of importance in the assessment of risks concerning environmental and social factors, for example human health.

## 6. ~~Considerations in a~~Assessing financial sustainability and stability

- 35.117 While the main focus in the discussion of sustainability in this chapter has been on natural and human capital, the same general principles of assessing sustainability can be applied to types of economic capital. Of specific relevance in some contexts are financial assets and liabilities and the extent to which there are imbalances within financial systems (financial stability) that might highlight concerns about the sustainability of the financial system. As well, the financial system will have connections to other types of capital for example in relation to the potential of demographic change to affect government finances and the effect of climate change influencing the frequency and intensity of natural disasters which in turn affect banking and insurance systems. The financial accounts within the SNA sequence of economic accounts provide a rigorous framework to provide baseline information describing the financial system and chapter 37 discusses how the SNA can be used in the analysis of financial sustainability.

~~35.118 Related to this, there is a general area of activity known as sustainable finance which considers the activities within the financial sector that are considered to be contributing to the achievement of more sustainable outcomes. These activities are most commonly reflected in new financial products and classes of financial assets such as green bonds. The development of more rigorous criteria for the definition and measurement of sustainable finance is progressing. <<To be developed further pending updates on IMF/OECD work in this space.>>~~

- ~~35.118~~ 35.118 As introduced above, a related area of work is the assessment of companies' exposure to environmental risks, including climate risks and risks emerging from declines in nature and biodiversity. This work extends from assessing the physical risks to quantifying the financial risks to corporations, including through their supply chains. Accounting-based data sets can be applied to support these assessments through the provision of baseline information. Two avenues of support can be envisaged. First through national and landscape scale public data presenting industry benchmarks and changes in the wider context for each company's operations (e.g. water scarcity, workforce skills) and second, through companies using accounting-based approaches to organize similar data for their own operations (e.g. on water use, greenhouse gas (GHG) emissions, workforce capability). These micro-macro connections are quite well-established for economic and financial data and are now developing in the environmental and social contexts often in the context of requirements for corporate reporting on sustainability. Examples of this include the requirements for GHG emissions reporting in the European Corporate Sustainability Reporting Directive and the Securities and Exchange Commission. These reporting requirements have been developed from initial work from the Financial Stability Board who developed the recommendations on climate-related disclosures and is extending to recommendations on nature-related disclosures. Ongoing research into the role of the SNA, SEEA and other accounting frameworks to support work in corporate reporting on sustainability is required, together with work on appropriate data collection vehicles.

## 7. Supporting the measurement of sustainable finance

- ~~— A related but separate area of measurement concerns sustainable finance. Related to this, there is a general area of activity known as sustainable finance which considers the financing activities within the financial~~

~~sector that are considered to be contributing to the achievement of more sustainable outcomes. Thus, These activities are most commonly reflected in new financial products and classes of financial assets such as green bonds. The development of more rigorous criteria for the definition and measurement of sustainable finance is progressing. <<To be developed further pending updates on IMF/OECD work in this space.>>~~

~~35.120~~35.119 ~~a~~ Alongside the increasing range of activity and policy response to the challenges of sustainability, there is increasing level of financing of these activities. While the financial instruments (e.g. loans, bonds, equities and investment fund shares/ units) that are used to provide resources are the same as those used for other purposes, separate quantification of the level of financing for sustainability purposes, for example measures of the value of green bonds, is important for tracking investment in the green and climate/transition economy and informing decisions on monetary and fiscal incentives relating to it (OECD, *Developing Sustainable Finance Definitions and Taxonomies*, 2020).

~~35.121~~35.120 The measurement of sustainable finance requires determining which components of the different financial instruments should be considered sustainable. This is an active area of research and discussion in many fora across both the private and public sector. Nonetheless, recognizing the policy relevance of the data, definitions have been determined in order to operationalize the concept of sustainable finance. ~~They also aim to serve as baseline definitions to help limit the potential for “greenwashing” which arises when inconsistent definitions are applied by different stakeholders.~~ These definitions should be reviewed in the light of further advances, especially in the context of changes in the regulatory and reporting requirements.

~~35.122~~35.121 Two primary types of sustainable finance are defined: ESG (Environmental, Social, Governance) finance and green finance with green finance being a sub-set of ESG finance. *ESG finance is finance for activities or projects that sustain or improve the condition of the environment or society or governance practices. Green finance is finance for activities or projects that sustain or improve the condition of the environment.* The general principle for establishing greenness is positive contribution to the environment, rather than “do no harm”.

~~35.123~~35.122 Countries are encouraged to compile measures of ESG finance and green finance as *of which* items for the following financial instruments: debt securities (AF.3), loans (AF.4), equity (AF.51) and investment fund shares/units (AF.52). The relevant breakdowns are shown in Table 35.3 below. The definitions of each of instruments are adaptations of the general definitions above. Thus, for ESG debt securities the scope concerns those where the use of proceeds is restricted to financing or refinancing activities or projects that improve the condition of the environment or society or governance practices or where the issuer agrees to achieve performance objectives that improve the condition of the environment or society or governance practices. For ESG loans the scope concerns those in which 50% or more of the debtor’s activities improve the condition of the environment or society or governance practices. For ESG equities the scope concerns those investments in institutional units in which 50% or more of the institutional unit’s revenue comes from activities that improve the condition of the environment or society or governance practices. For ESG investment fund shares the scope concerns those funds investing in financial instruments, companies, projects or other funds invested that intend to achieve performance objectives that improve the condition of the environment or society or governance practices. The definitions concerning green instruments have the same measurement scope except that they are limited to improving the environment.

~~35.123~~ Focus should be placed on recording the stock values for these financial instruments (*as of which* items in the financial balance sheets), with transactions being recorded as a second order of priority (*as of which* items in the financial accounts). If possible, the estimates should be provided for all of the main sectors and sub-sectors. ~~It is also recommended that f~~For debt securities, ~~the total ESG debt securities may should~~ be further broken down to identify the following of which ~~categories-items~~ in addition to green debt securities: social debt securities, sustainability debt securities, sustainability-linked debt securities and other ESG debt securities. ~~Focus should be placed on recording the stock values for these instruments with transactions being recorded as a second order of priority. If possible, the estimates should be provided for all of the main sectors and sub-sectors. Focus should be placed on recording the stock values for these instruments with transactions being recorded as a second order of priority. If possible, the estimates should be provided for all of the main sectors and sub-sectors.~~

	<i>Of which: ESG investment fund shares/<u>units</u></i>
	<i>Of which: Green investment fund shares</i>

35.124—

35.12535.124 There is a range of measurement challenges in implementing these recommendations that are addressed in associated guidance material<sup>2</sup>. A principal challenge is effectively determining whether the purpose of a given financial instrument satisfies the definition of sustainable finance. This may be determined by the label placed on the financial instrument and the certification approach. The following approaches are acceptable: (i) self-labelling, where the issuing entity decides on the ESG or green classification (ii), Second Party Opinion (SPO), where a trusted entity provides the ESG or green label; and (iii) certification, where, in the presence of standards (public or private), a specialized entity grants the ESG or green status. A, but since the labelling practices are not commonly independently assured, and the outcomes (in terms of improvements in environmental, social or governance condition) from the use of the finance cannot be known at the time the instruments are issued, a combination of approaches, potentially country specific, will need to be adopted. To combat concerns about “greenwashing”, it is important to provide metadata indicating what are the levels of assurance (through labelling and certification) that the estimates are ESG or green, and will require the collection of a range of metadata.

35.12635.125 To support assessments of the effectiveness of sustainable finance, it is relevant to link-present data on the levels of investment in ESG and green activities (as just defined) alongside to data about the outcomes arising from that activity, accepting that precise links may be difficult to identify. A particular focus for green finance may be reporting on the extent and condition of the natural capital stocks which the investments aims to improve. For example, for green debt securities measures of changes in the extent and condition of mangroves that have been the focus for the use of the funds would be relevant as part of understanding whether the planned activities (and the associated finance) are making a contribution to environmental outcomes. At a macro and landscape scale, data on stocks of capital and changes over time will support the identification of locations where sustainable finance may be best targeted.

35.12735.126 Consistent with these recommendations, BPM7 also encourages countries to compile measures of ESG and green finance, for the IIP (stocks) and BOP (flows) as “of-which” categories of debt securities, loans, equity and investment fund shares as separate-tables supplementary items outside the standard components. BPM7 also suggests compilation of other environmental indicators including the physical location of investments, direct investments in specific sectors as well as climate-related international cooperation grants to low-income countries (BPM7, Annex 10).

<sup>2</sup> To be developed based on OECD 2020 and the Issue Note on Sustainable Finance definition (February 2024)

## **8. Accounting for areas beyond national jurisdiction**

~~35.128~~35.127 In the measurement of natural capital, the accounts of the SNA and the SEEA are usually compiled for countries and hence the geographic scope is limited to the economic territory of a country including its EEZ. While this scope covers a reasonably large share of the world's natural capital, there is a significant amount of natural capital, in particular concerning oceans, that may be excluded. This includes natural resources such as fish stocks and seabed mineral resources and the ecosystem services provided by oceans such as in relation to global climate regulation, noting that if economic ownership can be established for natural resources, for instance via internationally agreed quotas, these resources are within scope of the SNA sequence of economic accounts.

~~35.129~~35.128 Where there is interest in organizing data about these types of natural capital outside of the scope of the SNA sequence of economic accounts in a manner that can be directly related to country based measures, the accounting definitions and treatments of the SNA and the SEEA can be applied. For example, it would be possible, conceptually, to compile accounts for the natural capital of the Pacific Ocean. A similar logic could be applied to develop accounts for the atmosphere on a more holistic basis.

## Chapter 36: Input-output tables

(moved upwards, revised title and revised content)

(OLD Chapter 28: Input-output and other matrix-based analyses)

**Commented [ED1]:** Consistency with the UN Handbook on Supply and Use Tables and Input-Output Table with Extensions and Applications has been applied with the aim of minimising changes to SNA, e.g., removal of obsolete terms or incorrect terms. Also, new terminology agreed for 2025 SNA.

**Commented [ED2]:** Introduction has been tidied up to align with the approach applied in other chapters and additional text to link to chapter 15.

**Commented [ED3]:** Brief reflection of the expanded role and use of input-output tables.

**Formatted:** Font: 10 pt, Italic

**Formatted:** Font: 10 pt, Italic

**Formatted:** Font: 10 pt, Italic

**Commented [ED4]:** X.28 reference, remove reference to SAMs and section D.

### A. Introduction

36.1 The purpose of this chapter is to build on the presentation of the supply and use tables in chapter 14.15 to examine in greater detail the possibilities offered by using a tabular and / or matrix form of presentation of the accounts. As has been noted on a number of occasions, the SNA is intended to offer a degree of flexibility in implementation as long as the inherent accounting rules are observed. The fact that the requirement to balance uses expenditures and resources revenues is immediately obvious within a matrix framework makes this a powerful way in which to explore different options while still ensuring the balances are satisfied. One aim of this chapter is to demonstrate the power of a matrix presentation in this way.

36.2 —

36.3 — Input-output tables

36.4 —

36.5 36.2 A second aim is to describe the basic ideas of input-output matrices tables. Supply and use tables are an integral part of the SNA and the process of compiling these tables is a powerful way of ensuring consistency between the various data sources available to the compiler. For many analytical purposes, though, a transformation from a pair of supply and use tables into a single input-output table where row and column totals are equal brings very considerable advantages. Input-output tables cannot be compiled without passing through the supply and use stage (except under very restrictive assumptions). They are therefore analytical constructs that inevitably involve some degree of modelling and assumptions in their compilation.

36.6 —

36.3 Similar to supply and use tables covered in chapter 15, the role and use of input-output tables has also expanded significantly over the past two decades. The input-output tables provide a powerful feedback loop in terms of quality and coherence of the supply and use tables both in current prices and in volume terms. This chapter not only covers the derivation of national input-output tables but also the multi-country input-output tables which form key inputs to analyses such as global value chains and trade in value added indicators.

36.7 36.4 There is a vast literature on the compilation and use of national input-output tables and it is impossible in a short chapter to give a full appreciation of the range of complexities of compilation and inventiveness of applications. Likewise various international organisations and research consortia have developed multi-country databases, and in turn, multi-country input-output tables. The chapter aims only to give a feel for the sort of operations necessary to transform national supply and use tables into national input-output tables and to give some ideas as well as compilation of their possible applications multi-country input-output tables. The Manual of UN Handbook on Supply and Use Tables and Input-Output Tables with Extensions and Applications (2018) and a visit to the web site of the International Input-Output Association (www.iioa.org) are good places to start a more detailed investigation of the potential in this field.

36.8 —

36.9 Social accounting matrices

36.10 —

36.11 Both the supply and use tables and input-output tables are matrix representations of the goods and services account. It is possible to cast the whole of the sequence of accounts, including the goods and services account, in a matrix format also. Such a matrix is called a social accounting matrix (SAM).

36.12 —

36.13 It is possible to extend and elaborate a SAM by introducing alternative disaggregations of existing flows or

new types of flows, just as long as the use and resource of these flows balance in the usual way. This is such a common extension of a SAM that the usual understanding of what a SAM is often goes further than a matrix encompassing the standard sequence of accounts to include extensions, particularly of the household sector.

36.14 —

36.15 — The structure of the chapter

36.16 —

36.17 — Chapter 14.15 describes how the supply and use tables may be used in order to ensure the internal consistency of disparate data sets. Section B of this chapter looks at two particular aspects of the supply and use tables where it may be useful to adopt a different approach to that described in chapter

36.18 — 14.15. The first of these concerns the treatment of insurance and freight on imported goods and the second concerns the treatment of goods that are processed by a unit that is not the legal owner of them. Section B also discusses how information cross-classified by establishment and industry can be transformed into information relating to institutional sectors.

36.19 —

36.20 36.5 — Section C is concerned with how a pair of supply and use tables may be transformed into a single symmetric input-output matrix table. Each of the supply and use tables shows disaggregation by products and industries. In an input-output table, one of these dimensions is eliminated. Thus a single table may show the relationship between the supply and use of products or alternatively the output of industries and the demand for the output of industries. Finally, section D covers multi-country input-output tables and the derivation and challenges involved.

Commented [ED5]: New section on multi-country input-output tables.

36.21 —

Section D goes on to show how the whole of the accounting system can be represented in matrix form. This is a useful pedagogical tool and may be instructive as a stepping-off point for extensions of the accounts such as social accounting matrices.

Formatted: Normal, Space After: 6 pt

**B. Flexibility in the supply and use tables**

**1. The treatment of margins on imports**

36.22 36.6 — In discussing valuation in section BC of chapter 14.15, consideration is given to how transport margins should be incorporated into the accounts and in particular how international transport charges should be recorded. Paragraphs 14.15.61 to 14.15.77 (to check) explain that the parallel between basic and producer prices does not carry forward simply to a distinction between CIF and FOB-based prices. The distinction depends on whether it is the unit providing the goods or the unit taking delivery of the goods that is responsible for providing the transport and insurance. Paragraph 14.15.77 (to check) ends by discussing briefly the practical problems in deriving the desired valuation from the available data sources. It is reproduced here for convenience.

36.23 36.7 — It may not be possible to determine from customs declarations which unit is responsible for the transport costs and, even when it is and conceptually the transport costs should be separated from the value of the goods themselves, there may be no information and no resources available to make the separation in practice. In such a case the CIF value of imports may be the only source with a disaggregation by type of good. If the disaggregated CIF figures are used for imports of goods, though, that part of the transport costs and insurance also included in imports of services would be double-counted. In order to avoid this, therefore, an adjustment column is inserted into the supply table. The adjustment column consists of a deduction from the services items for transport and insurance equal to the CIF-to-FOB adjustment for these items with an offsetting global adjustment made to imports of goods. Table 14.15.4, reproduced here as table 28.1 gives an example of such an adjustment.

**Table 2836.1: An example of imports entries in the supply table with the global CIF to FOB adjustment**

**Commented [ED6]:** This table will be removed as it is a duplicate of the new table 15.4.

[36.2436.8](#) This adjustment column shows the reallocation of service margins from the industries where they are produced (by resident or non-resident producers) to an adjustment row for the CIF/FOB adjustment. In the column for goods, the values given industry by industry include an element of these service margins; but this is deducted on the CIF/FOB adjustment row to leave the total equal to the total of imports FOB. The adjustments in this column are analogous to a similar column that could be shown illustrating the adjustment between purchasers' and basic prices.

[36.2536.9](#) A simpler procedure than that just described, though one not strictly consistent with [BPM6BPM7](#) recommendations, is to ignore the balance of payments division between goods and services and adjust the figures for imports of services by the amount of services provided by non-residents that are included in the detailed figures for imports of goods. This ensures that the total of imports of goods and services agrees with the total in the balance of payments but will not agree with the total of imports of goods FOB and of services shown there. This makes compiling the supply and use tables simpler but means that it is not possible to use imports of goods on a FOB basis to match exports of those goods from other countries. Even in this simpler version, however, the amount of freight and insurance on imports provided by residents must be shown as an export of services.

[36.10](#) [In this respect, it is important to note, as described in paragraph 15.77, that the valuation of imports and exports in relation to using CIF and FOB is likely to change to invoice values in the next update of the macroeconomic statistical standards.](#)

**Commented [ED7]:** G.I reference.

## 2. Goods processed by a unit not assuming economic ownership

[36.2636.11](#) A producer may carry out the same activity under quite different economic conditions. Consider farmers growing grain which is milled into flour before use. Suppose one farmer acquires a mill to process his own grain but once this is acquired he may offer to mill grain for others for a fee. The production account for the farmer with a mill will look somewhat different from that for a farmer who does not have a mill but pays the first farmer a fee for milling even though both produce flour for sale.

[36.2736.12](#) In the case of milling the reasons for [subcontractingsub-contracting](#) the activity to another may be the availability of suitable fixed capital. Increasingly, however, similar processes are being carried out internationally and in respect of activities more usually associated with manufacturing such as the assembling of component parts. Here the motivation is less one of the availability of capital than of the costs of labour. If the average wages in country X are half of those in country Y, it may be cost-effective for a unit in Y to dispatch the components to a unit in X for assembly and then have the completed product returned to Y or even shipped directly to a final purchaser.

[36.2836.13](#) [Previous editions ofPrior to the 2008 SNA have, it was recommended that components for assembly should be recorded as delivered to the unit in country X and that the whole of the value of the completed product should be recorded as output of X and exports from X to Y. This does not match the treatment of grain milling or, for example, repairs to machinery where no such change of ownership of the goods being processed is imputed. Imputing a change of ownership of the parts to be assembled gives rise to significant data compilation problems because the value of the assembled product may be greater than the cost of the components plus the fee to assemble them. The value of the finished product may incorporate the results of research and development of the unit contracting the assembly, for instance. The SNA-new recommends that products should only be recorded as being delivered to another unit if there is a change of economic ownership or, in the case where both producing units belong to the same enterprise, the producing unit taking delivery also assumes responsibility for subsequent risks and rewards of production such as deciding how much to process, what price to charge and when to sell.](#)

**Commented [ED8]:** Minimal historic reference.

[36.2936.14](#) The question arises of how to record the activity of assembling goods to order for another unit in

the supply and use tables and the input-output table. The processes of assembly for oneself and for another are physically similar but the economics are different.

~~36.30~~36.15 Suppose in year 1, a processing unit converts products only on own account. In year 2, the unit processes the same amount on its own account but also processes a similar amount on behalf of another. Suppose the cost of items processed in year 1 is 90, the cost of associated products needed to assemble them is 10 and the value added is 35. The total value of output is thus 135. In year 2, all other things being equal, intermediate consumption increases by another 10 to 110 and value added to 70 bringing the value of output to 180. The change in the structure of production is difficult to understand in the absence of information on the change in the role of the producer who is operating no longer only on his own behalf but also on behalf of others.

~~36.31~~36.16 There are essentially two ways to proceed. The first is to treat processing on own account and on behalf of another as different types of activity and different products. In this way in the second year the producer would have one activity with inputs of 100, value added of 35 and output of 135 as in the first year, plus another activity with inputs of 10, value added 35 and output of 45.

**Table ~~28~~36.2: Options for recording goods not changing economic ownership**

~~36.32~~36.17 The second alternative is to show the intermediate inputs in the second year as 200, value added as 70 and output as 270. Value added is the same under both options and the comparison between the second and the first year makes more sense from a transformation point of view under option 2. However, adding an extra 90 to both output and intermediate consumption is essentially artificial. Further, as noted above, it may be difficult for the processor to put a value on the components he receives and the output he provides to the other unit. The chances are that he only knows that he receives a fee of 45 to cover his incidental expenses of 10 and leave an amount of value added, 35 in this case. These options are shown in table ~~28~~36.2.

~~36.33~~36.18 ~~It should be emphasized that it is option 1 that is the recommendation of the SNA and recommended for goods sent abroad for processing. BPM6. Option 2 is shown as a supplementary presentation that may be adopted for reasons of continuity with past practices.~~ Option 1 more accurately reflects the economic processes taking place while option 2 focuses on the physical transformation process.

**Commented [ED9]:** Minimal historic reference.

~~36.34~~36.19 When goods are sent abroad for processing, they are recorded as neither exports of goods by the country holding economic ownership, nor as imports of goods by the processing country in either the SNA or ~~BPM6~~BPM. Similarly, after processing they are recorded neither as exports by the processing country nor as imports of goods by the country of economic ownership. The only item recorded as imports and exports is the fee agreed between the economic owner and the processor.

~~36.35~~36.20 The physical flows of the goods will continue to appear in the merchandise trade figures. However, the product code after processing may be different from the code on entry, making it difficult to match the incoming and outgoing flows.

~~36.36~~36.21 The presentation of option 2 suggests that the fee can be derived as the difference between the value of the goods on arrival and departure from the processing country but while this may sometimes give a reasonable approximation of the processing fee, there are many reasons why this may not be so.

- If processing takes any significant amount of time, there may be holding gains and losses affecting the value of the goods. These accrue to the economic owner, not the processor.
- Goods may be lost or damaged or may simply become obsolete while in process. (This has been observed in the case of electronic components.) These other volume changes also apply to the economic owner and not the processor.
- The value of the processed goods may be greater than the costs of the components and the processing fee to the extent that the finished product incorporates part of the value of R&D treated as fixed capital formation of the economic owner.

36.3736.22 All these situations reinforce the preference for option 1 over option 2 in table 2836.2.

### 3. Supply and use tables and institutional sector accounts

36.3836.23 As explained in chapter 4415, it is possible to derive a [balanced estimate of GDP using the three estimates of approaches to measuring](#) GDP from a set of supply and use tables. Since these tables can be expressed in volume terms, estimates can also be made of growth rates based on the tables. However, to complete the sequence of [economic](#) accounts, production accounts are needed by institutional sector. To ensure that the supply and use table and the sequence of [economic](#) accounts are perfectly integrated and consistent, it is desirable to take the part of the use table showing intermediate consumption and the components of value added and allocate the columns to institutional sectors.

36.3936.24 The starting point for the compilation is the part of the use table in table 4415.12 relating to intermediate consumption and value added. This is shown in a somewhat aggregated form in table 2836.3.

36.4036.25 The easiest allocation is for financial corporations since typically such corporations do not undertake secondary activity and other institutional units do not undertake any financial activity. When these conditions prevail, the column for the finance and insurance activity can be taken in its entirety as appropriate for the institutional sector. [As the output of the central bank is typically producing non-market output, this should be allocated to non-market output. Moreover, it is possible that financial corporations may undertake some production for own final use \(as capital formation\), in which case some part of an appropriate column in the section of table 2836.3 relating to own account production should be added. No such adjustment has been made in this example.](#)

Commented [ED10]: Issue X.3.

36.4136.26 [The](#)With the exception of the central bank (see above), the columns relating to non-market producers must be allocated between general government and NPISHs. In addition, though not in this example, it is possible that either general government or NPISHs may have an establishment undertaking market production. [This is how it is possible that non-market producers may have small amounts of operating surplus.](#) It is also possible that both general government and NPISHs may have some production for own final use (as capital formation) but none has been assumed here.

Commented [ED11]: Issue X.3.

Commented [ED12]: X.55, consistency with sum of costs.

36.4236.27 The last step is to allocate all columns not yet accounted for between non-financial corporations and households. An indication that some part of a market production activity should be allocated to households is the presence of mixed income as part of the value added of the activity. Thus, in this example, some parts of market production of agriculture, manufacturing, construction and trade are attributable to households as well as production for own final use. (As noted in general some of production for own final use will be attributable to other sectors. It is not done so here for reasons of simplicity at such an aggregate level.)

36.4336.28 Once these calculations are complete, table 2836.4 results, showing for each sector not just total intermediate consumption but also a product breakdown of this as well as the items for value added.

36.4436.29 The figures shown for intermediate consumption, output and the elements of value added for each institutional sector are those that appear in the production account and generation of [earned](#) income account in the sequence of accounts.

Table 2836.3: The use table from table 4415.12

## C. Deriving an input-output table

### 1. What is an input-output table?

36.4536.30 Essentially an input-output table is derived from a use table where either the columns representing industries in the two left-most quadrants are replaced by products or where the products in the two topmost quadrants are replaced by industries. The resulting intermediate consumption [matrixtable](#) is then square, showing products in both rows and columns or industries in both. In both cases the row totals for the complete [matrixtable](#) match the column totals for the complete [matrixtable](#), product by product or industry by industry

as the case may be. ~~The resulting matrices are therefore referred to as being symmetric.~~

36.31 ~~The resulting tables are often referred to as being symmetric input-output tables. From a conceptual point of view, however, it is incorrect to use the term "symmetric", in that the transformations reflect industry-adjusted product by industry input-output tables or product by product-adjusted industry input-output tables, which means, in essence, that there is no symmetry in the dimension of the table nor symmetric in mathematical terms but they are just square tables. Thus these tables should be referred to as "input-output tables" and not as "symmetric input-output tables".~~

**Commented [ED13]:** Consistency with the UN Handbook on supply and use tables and input-output tables with extensions and applications.

36.4636.32 The process of replacing the product dimension by an industry one is based on one of several possible models, to be discussed below. This process necessarily means that a ~~symmetric~~ input-output ~~matrix~~table is further removed from basic data sources than a supply and use table and it is therefore useful to review why making this transition is so useful.

36.47 —

36.4836.33 Note that in table 4415.12, there is a product for ores and minerals, electricity and water but no column for it. If there is no industry for which this is the principal product, identifying the primary producers rather than the number of products will determine the final size of the ~~symmetric (square) matrix~~ table.

**Table 2836.3 (cont): The use table from table 4415.12**

## 2. Analytical potential of an input-output ~~matrix~~table

36.4936.34 ~~Such~~Input-output tables have algebraic properties that make them particularly suitable for analyses that enable estimates to be made of the ~~direct effect, indirect effect and induced effects~~ of changing relative prices, of labour and capital requirements in the face of changing output levels, of the consequences of changing patterns of demand and so on. They may also be used as the basis for an expanded version that may be used to estimate the demands made by the economy on the environment, for instance.

36.5036.35 As noted in the introduction, there is a vast literature on how to compile and use input-output tables. The purpose of this section is simply to indicate the key aspects of converting a pair of supply and use tables into an input-output table.

36.5136.36 Suppose the entries in the inter-industry ~~matrix~~table are each divided by the figure for output at the bottom of the corresponding column, and the resulting matrix is designated as A; the vector of outputs is written as x and the vector of total final ~~demand~~uses is written as y. Then

$$Ax + y = x$$

This can be rewritten as

$$(I-A)x = y$$

or

$$x=(I-A)^{-1}y.$$

36.5236.37 The matrix (I-A) is known as the Leontief matrix, after the man who pioneered the use of input-

output tables and the matrix  $(I-A)^{-1}$  is known as the Leontief inverse. It is the last formulation that gives the analytical power to input-output analysis.

Formatted: Font: 10 pt, Superscript

36.53

36.5436.38 Suppose there is an increase in demand, for manufactured products, say. Looking at even the supply and use table it can be seen that to increase the output of these goods, more inputs of almost all types of products are needed. This increase in demand for a range of products is called the direct effect of a change in demand. However, the increase in demand in all these products causes a further round of increases in output for all products and this in turn triggers another set of increases in output and so on. Each round of effects is smaller than the last until it eventually becomes insignificant. The total of all second and subsequent round effects is called the indirect effect of a change in demand.

**Table 2836.4: Intermediate consumption and value added cross-classified by industry and institutional sector**

36.5536.39 In terms of the algebra just introduced, the direct effect is equal to  $Ay$ , the second round effect to  $A^2y$ , the third round effect to  $A^3y$  and so on. It can be shown that  $(I-A)^{-1}$  can be written as  $A+A^2+A^3+A^4$  etc. This is where the power of having a symmetric matrix comes from since  $A$  needs to be square for this formulation to work.

Formatted: Font: 10 pt, Superscript

Formatted: Font: 10 pt, Superscript

Formatted: Font: 10 pt, Superscript

Formatted: Font: 10 pt, Superscript

Formatted: Font: 10 pt, Superscript

Formatted: Font: 10 pt, Superscript

36.5636.40 As long as changes in demand,  $y$ , are sufficiently small that the average coefficients in  $A$  are likely to be good approximations to the new situation, the new level of  $x$  can be calculated. The approach breaks down if the changes in demand are so great that significant changes in  $A$  are likely to follow and marginal rather than average coefficients are needed.

36.57

36.5836.41 The matrix  $A$  is also sometimes called a matrix of technological coefficients and can provide insights into the way an economy works. In an economy dominated by primary products with little processing carried out in the domestic economy, there are relatively few significant non-zero elements in  $A$ . As the economy develops and processing of primary products becomes more commonplace,  $A$  becomes more populated with entries reflecting greater vertical and horizontal integration of activities within the economy. By exploring different industries associated with different stages in the production process it is possible to say where value added is generated. For example, cotton is grown as an agricultural product. It is then subject to separation into lint and seed (ginning), then the lint is converted to yarn and the yarn to fabric. If each of these activities appears in a different industry, it is possible to see where the value added between the growing of the cotton and the eventual fabric in which it is used arises.

### 3. Secondary products

36.5936.42 An industry classification such as *ISIC* essentially identifies industries in terms of the sorts of goods or services they typically produce. However, there are more products than industries and, for all sorts of reasons, some products may be made in several industries.

36.236.43 In order to limit the number of products per unit and to allow integration with basic production statistics, the concept of establishment is introduced. In principle, an establishment produces only one product at one location but the SNA recognizes that in practice it is not possible to separate production into such fine detail. Dealing with the fact that many establishments produce more than one product is fundamental to the idea of calculating a symmetric input-output matrix table.

36.60

36.44 Different choices of statistical units are available for the compiler and it is important to have a clear understanding of the impact of the choice of different statistical units has on the supply and use tables and on the input-output tables. For supply and use tables and input-output tables, the focus is on two specific

Commented [ED14]: Choice of statistical unit and impact of globalisation links to secondary production.

statistical units: enterprises and establishments (local kind-of-activity units). The establishment is the recommended unit for the compilation of the production part of the national accounts and therefore the compilation of supply and use tables and input-output tables. This means, as a rule, that multi-product enterprises must be partitioned into smaller and more uniform units regarding their kind of production, if possible. For more details on enterprises and establishments, see paragraphs 6.35 and 6.36.

36.64

**Table 36.28.4 (cont): Intermediate consumption and value added cross-classified by industry and institutional sector**

36.6336.45 The reason that manipulation of supply and use tables is needed to produce an input-output table is the existence of secondary products. If there were the same number of industries as products, and if each industry only produced one product, the supply table for the domestic economy would be unnecessary; the column totals for industries would be numerically equal to the row totals for products and the inter-industry **matrixtable** would be square as originally compiled. As noted elsewhere, the intent behind using establishments rather than enterprises, and working at a fairly detailed level in the supply and use tables, is to get as close to this situation as is reasonably practicable. Inevitably though some secondary production remains.

36.6336.46 There are three types of secondary production

- a. Subsidiary products: those that are technologically unrelated to the primary product. Just a few examples include a large retailer with a fleet of trucks used primarily for its own purposes that may occasionally offer transport services to another unit, a farmer who use part of his land as a caravan site, or a mining company that builds access roads and accommodation for its workers.
- b. By-products: products that are produced simultaneously with another product but which can be regarded as secondary to that product, for example gas produced by blast furnaces.
- c. Joint products: products that are produced simultaneously with another product that cannot be said to be secondary (for example beef and hides).

36.64 In order to reduce the supply and use tables to one single input-output **matrixtable** two possibilities exist. One is to express the input-output **matrixtable** in terms of products only;

36.6536.47 the other is to express the input-output table in terms of industries.

4. Reallocating secondary products

36.6636.48 There are two basic approaches to eliminating secondary products. Both come from applying information from the use **matrixtable** to the domestic output part of the supply **matrixtable** to reduce it to a purely diagonal one. Once this is done, the supply **matrixtable** contains no further useful information and is no longer presented. The transformed use **matrixtable** is what is referred to as an input-output **matrixtable**.

36.67

36.6836.49 In deriving a product by product **matrixinput-output table** in the simplest possible way, the final demand quadrant of the use **matrixtable** is unaltered. It already expresses demand/final use by product and does not need changing. The intermediate consumption and value added parts of the **matrixuse table**, though, need to be changed from an industry dimension to a product one. The row totals of the **matrixtable** already show the correct product totals so the exercise consists of reallocating entries from one column to another within the given row total. This is called **has been known as** a technology approach. It assumes that the demand for intermediate consumption and labour and capital inputs are determined by the nature of the products made. It is also worth noting that, in the transformations used where technology assumptions are applied, no technology in the physical production processes is involved, but only economic transactions measured in monetary terms. With the transformations, the institutional characteristics of the industries remain unaffected.

Commented [ED15]: Consistency with the UN Ha ... [10]

36.69—

36.7036.50 In deriving an industry by industry [matrix input-output table](#) in the simplest possible way, the value added part of the use matrix is unaltered and because the level of output will not alter, only the composition of intermediate consumption changes, not its total. Thus the exercise is one of reallocating items between rows but not between columns. In contrast to the product by product case, the quadrant relating to final [demand uses](#) will change and will show demand related to the industry supplying the products and not to the products themselves. This is called a sales structure approach. It assumes that as the level of output of an industry changes, the pattern of sales will remain the same.

**Table 3628.5: A numerical example of reallocating products from construction to manufacturing**

36.7136.51 Both these assumptions, the technology assumption and the sales structure assumption, are rather simplistic and in practice a more generalized approach may be used but it is helpful first to examine each of the assumptions in a little more detail.

**Product by product [input-output tables](#)**

36.7236.52 There are two ways in which a product by product [matrix input-output table](#) can be derived. These are:

- The industry technology assumption where each industry has its own specific means of production irrespective of its product mix.
- The product technology assumption where each product is produced in its own specific way irrespective of the industry where it is produced.

36.7336.53 It is simplest to explain these by example. In the upper part of table 4415.12, the construction industry is shown as producing 6 units (out of 208) of manufacturing products. In the lower part of table 4415.12, reproduced as table 2836.3, the inputs necessary for manufacturing and for construction are shown. These are reproduced in the first two numeric columns in table 2836.5. The next two numeric columns express these in percentage form. Thus, for example, one unit of manufacturing requires 0.038 units of agricultural products, 0.102 units of ores and minerals and so on. Construction uses no agricultural products, 0.005 units of ores and minerals and so on.

36.74—

36.7536.54 In order to create the product by product [matrix input-output table](#), it is necessary to deduct the costs associated with the production of 6 units of manufactured goods from the column for construction and add it to the column for manufacturing. On completion of this exercise for all secondary production, the columns will represent products rather than industries.

*Industry technology assumption*

36.7636.55 Under the industry technology assumption, the coefficients showing how manufactured products are produced are assumed to depend on the industry they happen to be produced in. Thus to reallocate the 6 units of manufacturing products from the construction industry to a column that will now refer to manufactured products only (ignoring other secondary products for the moment) a set of inputs, derived as 6 times the coefficients for construction is added to the manufacturing column and deducted from the construction column. The results of this are shown in the fifth and sixth numeric columns of table 2836.5.

### Product technology assumptions

~~36.77~~36.56 Under the product technology assumption, the coefficients showing how manufactured products are produced are those of the manufacturing industry regardless of where they are actually produced. In this case, to reallocate the 6 units of manufacturing products from the construction industry a set of inputs derived as 6 times the coefficients for manufacturing is added to the manufacturing column and deducted from the construction column. The results are shown in the seventh and eighth numeric columns of table 36.5.

36.7836.57 It is important to note a problem that arises under this assumption. When the product technology assumption is used, manufactured products produced by the construction industry are assumed to use a small amount of food. However, no agricultural products are actually recorded as being used in the construction industry so deducting these inputs from the recorded entries for construction leads to a negative entry. Negative entries cannot appear under the industry technology assumption. Since negative entries are logically impossible, this is one argument in favour of using the industry assumption rather than the product assumption.

### Industry by industry input-output tables

~~36.79~~36.58 Just as there are two ways in which a product by product ~~matrix~~input-output table can be derived, there are two ways in which an industry by industry ~~matrix~~input-output table can be derived. These are:

- The fixed product sales structure where it is assumed the allocation of demand to users depends on the product and not the industry from where it is sold.
- The fixed industry sales structure where it is assumed that users always demand the same mix of products from an industry.

~~36.80~~36.59 Although a table similar to table ~~28~~36.5 is not presented for the industry by industry input-output tables, its construction is similar and straightforward but would show the entries across the rows of the use tables rather than down the columns.

36.60 In order to create an industry by industry input-output table, it is necessary to move the use of 6 units of manufactured products from the row for the manufacturing to the row for the construction. On completion of this exercise for all secondary production, the rows will represent industries rather than products. It is worth noting that, if an enterprise is broken down into separate establishments, actual data on transactions between these establishments may be available to inform the compilation of an industry by industry input-output table.

### Fixed industry sales structures

36.61 Here the 6 units of manufactured goods supplied by the construction industry are reallocated to the construction row from the manufacturing row using the proportions of the construction row. Such a table can contain negative elements.

### Fixed product sales structure

~~36.81~~36.62 In this case, to allocate the 6 units of manufactured goods supplied by the construction industry to the row for construction, a proportion of the row for manufacturing is allocated to the construction row using the proportions in the manufacturing row. It follows that such a matrix will not contain negative entries.

### Fixed industry sales structures

~~36.82~~ Here the 6 units of manufactured goods supplied by the construction industry are reallocated to the construction row from the manufacturing row using the proportions of the construction row. Such a matrix can contain negative elements.

Formatted: Not Highlight

Formatted: Not Highlight

Commented [ED16]: Re-ordering of the sequence of the models C and D aligns with the UN Handbook and Eurostat Handbook and other literature.

The choice of approach to be used

- 36.8336.63 There are four basic choices open to the input-output compiler
- a. A product by product approach using a product technology assumption,
  - b. A product by product approach using an industry technology assumption,
  - ~~c. An industry by industry approach assuming a fixed product sales structure,~~
  - c. An industry by industry approach assuming a fixed industry sales structure.
  - d. An industry by industry approach assuming a fixed product sales structure.

Options a and c~~d~~ may result in negative entries; options b and d~~e~~ do not.

36.8436.64 Both product by product and industry by industry input-output tables may be compiled. They serve different analytical functions. For example, to ensure that price indices are strictly consistent, a product by product matrix input-output table is to be preferred. For a link to labour market questions, an industry by industry input-output table may be more useful. Although traditionally a lot of interest focused on the product by product input-output tables, this was accompanied in large part by an attention to the underlying technology. Increasingly the economic interaction of different industries has brought more interest in the industry by industry input-output tables.

Hybrid approaches

36.8536.65 In practice, no single method is used on its own. Knowledge of the type of product or industry in question should dictate whether an industry-based conversion procedure or a product-based one is most appropriate. Some secondary products may be dealt with one way and others another despite the fact that, on occasion, negative values may initially appear.

36.86

36.8736.66 The extent of variation between the various approaches will depend on a number of factors, including in particular the extent of secondary production in the supply matrix table. In general, the greater the degree of disaggregation and thus the less secondary production to be reallocated, the closer the input-output tables will resemble the supply and use tables. Indeed some countries prefer to work with very detailed supply and use tables and not produce symmetric input-output tables at all.

36.88

36.8936.67 As an illustration of the differences involved, tables 2836.6 and 2836.7 show the results of converting the supply and use tables in chapter 4415 to, first, a product by product matrix input-output table using only the industry technology assumption and then an industry by industry matrix input-output table using only the product sales structure.

Table 3628.6: Example of a product by product input-output matrix

Table 3628.7: Example of an industry by industry input-output matrix

The database required for the transformation

36.9036.68 The starting point for the production of a symmetric input-output table is a pair of supply and use tables both at basic prices. Even the calculation of the use table in basic prices is one step away from basic statistics and actual observations, reinforcing the fact that the input-output tables are analytical constructs, not a compilation of directly observed phenomena.

36.91

Commented [ED17]: Re-ordering of the sequence of the models C and D aligns with the UN Handbook and Eurostat Handbook and other literature.

Table 28.6: Example of a product by product input-output matrix

36.9236.69 Further, it is advantageous to separate the use table at basic prices into two, one showing those elements relating to domestic output and the other those elements relating to imports. The statistical requirements for such a separation are demanding but the results allow considerable flexibility in the treatment of imports and permit a clear analysis of the impact of demand on supplies from resident producers and on foreign suppliers.

36.93 —

36.9436.70 The exact manner of dealing with imports is a subject of considerable complexity where a number of options are available also. In some economies, some important products will only be imported and so separating these “non-competing” imports from the rest may be of particular interest.

36.95 —

36.9636.71 Another topic that requires careful consideration is the degree of detail that is desirable for product and industry classifications. This may vary depending on the resources available to the statistical office and the sort of use to be made of the results.

Table 28.8: The goods and services account in matrix form Input-output and other matrix-based analyses

Social accounting matrices

Commented [ED18]: X.28 reference, remove Section D.

Expressing the sequence of accounts in matrix form

The part of the use table relating to the destination of products represents one side of the goods and services account in matrix form. However, it can also be expressed as a series of sub-matrices; one for intermediate consumption, one for final consumption, one for capital formation and one for exports. These sub-elements can be associated with the production account, the use of income account, the capital account and the rest of the world account respectively. Similarly the supply table represents the other side of the goods and services account but can also be written as two sub-matrices, one associated with the production account (output) and one with the rest of the world (imports). By writing the supply table horizontally and the supply table vertically in terms of these sub-matrices and their associated accounts, table 28.8 emerges. The rows and columns labelled E denote the total economy and those labelled R the rest of the world.

The attraction of this format is that the total across the set of rows for the goods and services account is equal to the total down the columns for the same account. There is no match for the second set of rows for the production account, but it is not difficult to bring this about. The entries for value added can be inserted in a third set of rows with the entries underneath intermediate consumption. In this way the sum down the columns for the production account is then equal to the rows for the same account. But there is now an unmatched third set of rows containing value added. Since value added ultimately carries forward to the allocation of primary income account, the third set of rows can be so labelled as in table 28.9.

If, to match this third set of rows, a third set of columns is inserted between the production account columns and those for the use of income account, property income can be inserted at the intersection of the third set of rows and columns and a fourth set of rows inserted to show the balance of primary income as it appears in the secondary distribution of income account. Proceeding in this way, successive sets of rows and columns can be introduced until the whole sequence of accounts is covered, as in table 28.10.

By including the entries for the rest of the world as well as for the total economy, the balancing items from the balance of payments can be shown as, for instance, the 41 in table 28.9.

It is also possible to extend table 28.10 to show the incorporation of the balance sheets as in table 28.11. For this, a row above the initial table is introduced to show the opening balance sheet and three rows below it. The first of these shows the entries for the other changes in the volume of assets account, the second relates to the revaluation account and the last is the closing balance sheet. Two adjustments also need to be made to table 28.6. The first concerns the item for the consumption of fixed capital, which is transposed from the row for the capital account and column for the production account and placed in the column for the capital account and row for the production account but with a negative sign. The second is to subdivide the capital account with the first set of rows and columns covering all items in the account but the second set covering the product details for gross capital formation and thus forming part of the asset account for non-financial assets.

Reading down the columns starting with the opening balance sheet entry for fixed assets, for example, this value plus the value of capital formation, less consumption of fixed capital, plus other changes in the volume of assets plus revaluation items is equal to the value on the closing balance sheet. For financial assets less liabilities the matching identity holds.

#### Expanding the matrix

It is possible to expand and rearrange the rows and columns of the matrix so long as this is done consistently in both dimensions. It is not strictly necessary to adhere to the order of the sequence of accounts or the degree of detail shown there. The transactions to be included can be expanded or contracted as can the sets of institutional units to be identified.

Table 28.9: The supply and use table in matrix form

The example of transposing consumption of fixed capital from being a positive entry on one side of the account to a negative entry on the other demonstrates how the matrix formulation may be used to enhance the articulation of the asset accounts.

It is also possible to include alternative classifications of key items. For example a row called "human needs" could be included showing how much food, housing etc was needed for each group of households, based on the functional classification of household consumption. In the column for consumption expenditure, the set of needs can be then cross-classified by product and household group.

A further expansion of the matrix may be to show the from-whom-to-whom details of such flows as property income and transfers.

The matrix presentation is very powerful in terms of the flexibility it can encompass, and in displaying the interaction of the accounts in a compact and graphic manner. On the other hand, there are disadvantages to the matrix presentation also.

Without explanatory text describing each of the main elements, a reader has to have a very good understanding of the SNA to interpret the numeric entries in the table.

Such a table always contains lots of white space which means that it is not an effective way of presenting a large amount of data.

In general, the matrix format is best used to explain the structure of the accounts being presented with individual cells, or a combination of cells, following in a more traditional format.

#### Disaggregating households

Expanding the accounting matrix of the sequence of accounts to incorporate the disaggregation of households is the usual form of a satellite account known as a social accounting matrix (SAM). As such it moves beyond a rigorous accounting structure based on observations to make an allocation of income into household groups possibly based on a household income and expenditure survey. In some cases this is based on a single survey. The problem, as explained in chapter 24 on the household sector, is that income flows in the SNA relate to individuals whether as employees, recipients of property income or transfer recipients while expenditure relates to households. Mapping individuals to households is necessarily difficult and depends to a greater or lesser extent on a set of assumptions. Any analysis of how government policies will affect households and their consumption depends on making such a mapping.

#### A SAM for labour accounts

One example of where a SAM is useful is in the case of labour accounts, showing the level and composition of employment and unemployment. SAMs have often provided additional information on this issue, via a subdivision of compensation of employees by type of person employed. This subdivision applies to both the use of labour by industry, as shown in the supply and use table, and the supply of labour by socio-economic subgroup, as shown in the allocation of primary income account for households. It implies that the matrix presents not only the supply and use of various products, but also the supply and use of various categories of labour services.

In order to have a comprehensive picture of the relationship between households and the labour market, the following sets of information are likely to be needed:

Various stocks underlying the flows in the SAM, such as size and composition of the population by household group (including the potential labour force) and production capacity by industry;

For the self-employed, it may be desirable to have information on the possession of assets (for example, agricultural land, consumer durables) as well as information on financial assets and liabilities;

Related non-monetary socio-economic indicators, such as life expectancy, infant mortality, adult literacy, nutrient intake, access to (public) health and education facilities, and housing situation by household group (see *Towards a System of Social and Demographic Statistics* (United Nations, 1975));

Some re-routings such as social transfers in kind by groups of households.

Comparing labour incomes of all employed persons as shown in the SAM, a decomposition of these incomes into full-time equivalent employment and average wage rates, and the potential labour force by type of person and household group (expressed in "full-time" equivalents), yields detailed information on the composition of unemployment and an aggregate indicator ("full-time equivalent unemployment") which is consistent,

both conceptually and numerically, with the other macroeconomic indicators; these can also be derived from the SAM framework.

## D. Multi-country tables

- 36.72 The emergence of global value chains challenges conventional wisdom on how we look at economic globalisation and, in particular, the policies we develop around the analyses of the impacts of globalisation, including environmental footprints. This has also led to the compilation of statistics on global value chains and multi-country supply and use tables and multi-country input-output tables to estimate trade in value added indicators, see chapter 23 for more detail on global value chains and trade in value added indicators. The role of national supply and use tables in generating multi-country supply and use tables and multi-country input-output tables is covered in this section.
- 36.73 In the absence of an internationally agreed statistical guidance to compile multi-country tables, international organisations and various research consortia have developed databases of national supply and use tables and national input-output tables as well as modelling for missing countries and missing data, as a starting point for compiling multi-country tables. In this respect, it is important to note, these databases reflect different assumptions (e.g., to remove trade asymmetries) and modelling techniques, thereby producing different estimates.
- 36.74 The GIANT (Global Input-output AccountNTs) initiative is an inter-agency network consisting of the Asian Development Bank, the European Commission, the International Monetary Fund, the Organisation for Economic Co-operation and Development, the United Nations Economic Commission for Africa, the United Nations Economic Commission for Latin America and the Caribbean, and the World Trade Organisation. In this respect, the GIANT initiative has been set up to converge to a common benchmark of input data into the various existing regional initiatives that compile multi-country supply and use tables and multi-country input-output tables, thus ensuring at least mutual comparability and consistency among them - thus the GIANT initiative is key. This initiative also seeks to help provide users with consistent messages and results in terms of, for instance, global value chain participation or estimation of carbon footprints, irrespective of the specificities of any given multi-country supply and use tables or multi-country input-output tables.

**Commented [ED19]:** X.28 (outline) briefly covering the move from national supply and use tables to multi-country supply and use tables and multi-country input-output tables. Also the link to their uses in terms of global value chains and trade in value added indicators.

### 1. Moving from national supply and use tables to multi-country input-output tables

- 36.75 Moving from national supply and use tables to multi-country supply and use tables involves firstly the combined use of national accounts, balance of payments and merchandise and services trade statistics to breakdown the main national accounts aggregates by product and by industry in a fully-fledged multi-country supply and use tables framework. However, there are conceptual differences between both datasets that constitute additional challenges in the compilation of multi-country supply and use tables.
- 36.76 Although methodological differences between merchandise trade flows and national accounts trade statistics exist, in practice (in part because not all countries are able to fully-align with the ownership principle of the SNA) these are generally not significant at the aggregated level (e.g., country's total exports of goods). However, there are significant challenges when considering particular products, activities and trading partners and these are briefly mentioned in this section.
- 36.77 Some of the specific challenges moving national supply and use tables to multi-country supply and use tables include:
- Splitting exports of goods and services for intermediate use or final uses and align these flows to the underlying ownership principles, in particular processing and merchanting activities as well as products that may have dual uses (e.g., as intermediate use or final uses).
  - Domestic exports or re-exports requiring detailed trade flows information about the country of origin (producer), country of consignment (re-exporter) and traded product.
  - Bilateral exports resolving the trade asymmetries to determine the geographical distribution of total (domestic) exports from one country to another.

**Formatted:** Indent: Left: 0.59", Hanging: 0.3", Tab stops: 0.59", Left + Not at 0.47"

- Estimation of direct purchases abroad (imports) by product or service, country of purchase and country of residence of the purchaser to be derived from limited data sources.

36.78 Major steps for compiling the multi-country supply and use tables include:

- Collection and compilation of harmonised national accounts control totals, for example, imports of goods separate from services and likewise for exports of goods and services.
- Estimation of balanced foreign trade flows with rebalanced national supply and use tables and balancing cross-country trade flows by product.
- Link the import use tables by bilateral trade partner shares or alternatively, link the total exports by bilateral trade partners to import use tables. The first approach uses balanced trade statistics to split import use tables by country of origin (and implicitly estimate bilateral exports). The second approach uses balanced trade statistics to split total exports from supply and use tables at basic prices across trading partners and then use the import use tables (FOB) to split across intermediate uses and final uses.

Formatted: Not Highlight

Formatted: Not Highlight

36.79 Once multi-country supply and use tables are compiled, the methods and assumptions used to produce national input-output tables from national supply and use tables can be applied to produce multi-country input-output tables from multi-country supply and use tables. Alternatively, multi-country input-output tables can be produced from national input-output tables. However, these would not be consistent with multi-country supply and use tables, in particular in relation to the different assumptions made by countries to produce national input-output tables, also based on unbalanced trade statistics.

36.80 The standard format of multi-country input-output tables includes intermediate consumption, value added and final use sections similar to national input-output tables (see an example conceptual diagram in figure 36.1). The final uses of each country is the sum of final consumption expenditure and gross fixed capital formation of domestic and imported products, changes in inventories, exports as well as direct purchases abroad by residents. However, the definition of intermediate transactions is broader in a multi-country input-output table than the national concept as the export from one country could be for example, be either intermediate use or final use in the importing country. In addition, taxes paid abroad such as tourism and value added taxes paid on direct purchases abroad are explicitly separated at the bottom of tax receiving territories.

36.81 Many statistical and methodological challenges remain to improve the coverage and quality of the databases covering multi-country supply and use tables and multi-country input-output tables. Methodological enhancement includes asymmetric issues in bilateral trade flows in cross border and direct purchases, taxes and distribution services as well and valuation differences in merchandise trade statistics. To address these challenges and database developments, there are initiatives being coordinated amongst the international statistical organisations to unify and develop a database with agreed assumptions and data, for example, the GIANT initiative mentioned earlier.

36.82 There is various literature that documents the steps to compile multi-country input-output tables and more detail on the additional challenges that need to be addressed, for example:

Eurostat's FIGARO tables:

## 2. Uses of multi-country tables

36.83 There are various uses of multi-country supply and use tables and multi-country input-output tables as well as feeding into the production of different analytical products. The following briefly touches on global value chains and trade in value added indicators.

36.84 Production, trade and investments are increasingly organised within so-called global value chains where the different stages of the production process are located across different countries. These global value chains have become a dominant feature of world trade, encompassing developing, emerging and developed economies. More details on global value chains are covered in chapter 23 and available in:

*United Nations, Department of Economic and Social Affairs, Statistics Division (2021). Accounting for Global Value Chains: GVC Satellite Accounts and Integrated Business Statistics, Studies in Methods, Series F no. 120.*

UNSD web page on GVCs:

36.85 The goods and services we buy are composed of inputs from various countries around the world. However, the flows of goods and services within these global production chains in conventional measures of international trade are not always reflected in a way which serves certain types of analysis. The trade in value-added initiative addresses this issue by considering the value added by each country in the production of goods and services that are produced and consumed worldwide. More details on trade in value-added indicators are available in chapter 23 and available in:

Consistency with the UN Handbook on supply and use tables and input-output tables with extensions and applications.		

## Chapter 37: From-Whom-To-Whom Tables and related financial indicators

(New chapter with loose links to SNA 2008 Chapter 27)

The chapter includes, especially in paragraph 37.13, a framing of the transactor approach versus the debtor-creditor approach which does not propose any changes to the current standards in the 2008 SNA and the BPM6, but regarding which it has not yet been possible to arrive at a consensus among members of the AEG. The exact phrasing of the issue will be further discussed in the course of July, in close collaboration with the Balance of Payments Committee. The resolution of this issue will be communicated in due course.

### A. Introduction

- 37.1 This chapter describes the from-whom-to-whom (FWTW) dimension of the relevant components in the sequence of economic accounts as well as a series of institutional sector related financial indicators. It focuses on the increased importance of highlighting the inter-relationships among the institutional sectors of the economy using the transactor approach, in terms of financial transactions and stockpositions as well as non-financial transactions. This chapter also discusses the usefulness of financial indicators in better understanding the financial situation of the institutional sectors, both individually and how they relate to each other, as well as to the economy as a whole.
- 37.2 The SNA standard presentation of institutional sector accounts, as presented in the sequence of economic accounts in chapters 8 to 14, is not explicitly designed to show the intersectoral linkages, as it mainly focuses on answering “who does what”, and not “who does what with whom”.
- 37.3 However, the SNA provides an integrated framework for developing data on financial transactions, other flows and balance sheets, as well as current and capital transactions, on a FWTW basis, because its underlying principles ensure that the linkages of the economic and financial actions of an economy and its sectors are captured.
- 37.4 Promoting the implementation of the FWTW intersectoral relationships for financial stockpositions and flows together with the institutional sector accounts is an important step towards filling one of the most significant data gaps identified during the global financial crisis that began in 2007-08.
- 37.5 The integrated framework on a FWTW basis allows certain questions to be answered, such as: who is financing whom and who is exposed to whom, to what amount, and with which type of financial instrument? As regards the allocation of income, it also permits tracing who is paying income (e.g. interest and similar returns, hereafter referred to as interest) to whom and who is receiving income from whom.
- 37.6 The reasons to collect, compile and present FWTW flows and stocks are analytical but also statistical:
- FWTW statistical information considerably enriches the method of monitoring the transmission of monetary policy and the impacts of financial shocks. Because price and interest changes of the various financial assets and liabilities of the various sectors play a major role in this process, the analysis may also focus on stock-flow adjustments among the various institutional sectors. In this respect, FWTW statistical information makes it possible to analyse how inter-sectoral relationships for flows and stocks of financial assets and liabilities have changed as a consequence of policy decisions and other events;
  - This information also helps to identify data problems and improve quality, as well as improve consistency across related statistical products. Datasets can be covered by more than one data source (which may also provide ~~be~~ an opportunity to enhance consistency across related macroeconomic statistical products), by only one data source, and by no data source owing to the lack of primary statistics. An example of a data point with no data sources might be trade credits provided by non-financial corporations to households. If sub-instrument FWTW details on trade credits are available in some sources and incorporated in the macro data set, then the household estimates can be improved in quality (from a pure residual approach).

- 37.7 This chapter complements Chapter 8 of the Monetary and Financial Statistics Manual and Compilation Guide (MFSMCG) 2016 that deals with financial statistical tables and the IMF's balance sheet approach to financial stability work, as well as the chapter 6 of the UN handbook on Financial Production, Flows and Stocks in the System of National Accounts (FPFS) 2015 that discusses the from-whom-to-whom tables.
- 37.8 Section B presents a concise overview of the general structure of FWTW-tables, while section C deals with some key data sources, such as source data containing counterpart data and security-by-security databases. Section D shows some possible uses of detailed FWTW tables. Section E concludes this chapter with an overview of financial indicators that can shed light on financial risks and vulnerabilities.

## **B. Overview of table structures and additional considerations**

- 37.9 There are essentially two data structures within institutional sector accounts, both of which basically present similar information albeit in a different format: matrix-type of presentation and presentations of FWTW-information in a time series format. These may relate to [stockpositions](#) of financial instruments, financial transactions, certain income and capital transactions, revaluations and other changes in volume data. While it is possible to construct matrix-type of FWTW tables for different periods, the time series perspective provides a better view on select information for consecutive periods.

### **1. Matrix-type of presentations of institutional sector accounts**

- 37.10 The matrix structure presents, for selected flows or [stockpositions](#) recorded in the sequence of economic accounts, an overview of the interlinkages between [\(sub\)sectors](#) and counterpart [\(sub\)sectors](#), [including those within \(sub\)sectors](#), for a certain period (in the case of flows) or at a certain point in time (in the case of [stockpositions](#)). Such matrices have been in use for some time but have gained much more prominence after the global financial crisis that began in 2007-08. This crisis clearly showed the relevance of these interdependencies, and the related financial risks and vulnerabilities, between sectors and countries, leading to a cascade of events spreading across the world.

#### **Balance sheet matrix**

- 37.11 The balance sheet matrix presents, for any given point in time, the stocks of financial assets and liabilities, whereby the holders of financial assets, typically presented in the columns of the matrix, are cross-classified with the issuers of the relevant liabilities, typically presented in the rows of the matrix. As in the case of the sequence of economic accounts, for each instrument, total assets equal their corresponding liabilities. The balance sheet matrix may provide FWTW details by transactor for selected instruments, such as debt securities and their characteristics (such as currency and maturity), but may also relate to the sum of or the details for all financial assets and liabilities (see Table 8.5 in the MFSMSCG 2016), or to a certain grouping of financial assets and liabilities which is of particular interest. It is a statement of the financial [stockpositions](#) of sectors as well as the linkages between institutional sectors and shows the accumulation of funds having been transferred from surplus to deficit sectors alongside the corresponding financial exposures of sectors to other sectors.
- 37.12 Table 37.1 provides a basic example of the relationship between [issuers \(debtors\)](#) and [holders \(creditors\)](#) for debt securities, with [issuers](#)~~editors~~ on the horizontal axis and [holders](#)~~debtors~~ on the vertical axis.

Table 37.1: FWTW table for stockpositions in debt securities

HOLDERS® ----- ISSUERS™	Resident non- financial corporations	Resident financial corporations	Resident general government	Resident households and NPISHs	Total economy*	Non- residents	Total All holders (matrix total)

Resident financial corporations	10	30	10	20	70	30	100
Resident general government	30	100	10	80	220	80	300
Total economy	60	220	30	140	450	150	600
Non- residents	30	50	10	10	100		100
Total All issuers (sector totals)	90	270	40	150	550	150	700

\*Sum of resident sectors

## Financial account matrix

37.13 The financial account matrix is similar to the balance sheet matrix, except that it records transactions in financial assets and liabilities in a certain period of time, broken down by sector and counterparty sector using the transactor approach. In particular for tradable securities, the transactor approach means that for *primary market* transactions new issues (liability) and the purchases (asset) of those issues are netted (i.e., gross new issues are recorded net of redemptions/repurchases); and in the case of subsequent *secondary market* activity, the asset-side transactions in those same securities are also shown net (i.e., purchases less sales) without explicitly accounting for the changes in the counterparty sectors of the issuers (debtors) as financial transactions. This information can be ~~very~~ useful in identifying how net borrowing sectors finance their deficits and which net lending sectors provide the necessary funds. Like the balance sheet matrix, the financial accounts matrix may be compiled for selected financial transactions, or for certain grouping of financial instruments. For example, table 37.1 above can also be constructed for transactions in debt securities, possibly delineating the counterparties of new issues of debt securities from the purchases and sales of outstanding securities. Some countries may also be able to present supplementary information on gross basis, with respect to transactions in securities.

37.1337.14 More generally, it can be noted that while the financial accounts matrices can provide more immediate information on the counterparty relationships and particularly identify changes in the counterparties, the quality of the available data from the financial account matrices will likely be lower than the quality of the data from the balance sheet matrices which are typically the starting point for compiling financial accounts matrices.

## 2. FWTW-information in a time series format

37.1437.15 While the matrix presentation is very useful for providing a bird eye's view of the interrelationships between sectors, analysis often requires a focus on the developments over time of the interrelationships for any given sector(s) and any given financial instrument. This can be done by re-ordering the information in the FWTW-matrices in a time series format, whereby for a certain financial instrument each of the sectors holding the assets show a breakdown of the sectors which have issued the relevant financial asset.

37.1537.16 A FWTW table in time series format presents the inter-sectoral relationships for a given instrument over time on a transactor basis. It displays the evolution of selected financial instruments

from both the asset and the liability perspective, thus allowing the users to analyse the changing patterns in the financing by issuers (debtors) and the related financial exposures of holders (creditors) over time, and also allowing for a deeper understanding of the financial risks and vulnerabilities of a certain sectors or the economy as a whole.

37.1637.17 Table 37.2 is basically a re-arrangement of Table 37.1. The time series dimension is presented on the horizontal axis, while holders (creditors) and issuers (debtors) are shown sequentially on the vertical axis.

**Table 37.2: FWTW-table for stockpositions in debt securities in a time series format**

### 3. Additional considerations on FWTW-tables

~~37.17~~37.18 Although the FWTW-tables presented above show information on the interrelationships between the main sectors for ~~a certain~~ main categories of financial instruments, they are still aggregated ones that, while useful, may be somewhat limited in their analytical capacity. For example, it may be important to know the long-term and short-term split of debt securities, or to have details on debt securities denominated in domestic currency versus those denominated in foreign currency. It may also be considered useful to have deeper breakdowns of sectors and counterparty sectors. As an example, a demand to better understand non-depository financial institutions is greatly enhanced by including financial corporations' subsectors in FWTW-tables. The level of detail will obviously depend on the availability of the required source data, which is discussed in section C below.

~~37.18~~37.19 While the discussion thus far has focused on debt securities, as noted before, FWTW-tables can be constructed for any of the financial instruments, either stocks or transactions, source data permitting. However, certain financial instruments such as loans, debt securities and equity tend to feature more prominently in FWTW-tables because they tend to be key sources of lending and borrowing, subject to various types of risks and vulnerabilities and usually a variety of sectors involved.

### 4. Extensions of FWTW-tables

~~37.19~~37.20 FWTW-tables have generally been understood to cover financial stock~~positions~~ and/or financial transactions by instrument, as generally illustrated by tables 37.1 and 37.2. However, the inclusion of selected components of the current and capital accounts can add to the analytical usefulness of these statistics. Certain components of the current and capital accounts lend themselves quite readily to the FWTW-table structure, such as earned income transactions as well as current and capital transfers.

#### *Earned income transactions - investment income*

~~37.20~~37.21 Earned income components can also be cast in the FWTW-framework, and some countries have adopted a FWTW-table approach for investment income. This articulates income associated with financial instruments by issuer (debtor) and holder (creditor) sectors. These can be used for analysis of the flows of interest and dividends by institutional sector and counterparty sector. It can also serve as a tool for data quality purposes, ~~by~~ By checking the consistency of financial stock~~positions~~ with related flows of investment income. For example, the relationship between interest or dividend transactions in the current accounts with related debt or equity instruments in the balance sheets, together with information on holding gains and losses can generate average implicit yields that help to interpret the financial stock~~positions~~ of sectors.

#### *Current transfers*

~~37.21~~37.22 Revenues and expenditures for transactions recorded in current transfers other than social transfers in kind account can also be compiled on a FWTW-basis. For example, there may be policy or analysis related interest for additional details on current taxes by type, or social contributions and benefits, or the components of other current transfers in terms of which (sub)sectors are paying and receiving. As another example, for employer's pension plans one could combine the FWTW-tables for components of investment income, income transfers, financial transactions and stock~~positions~~, to provide an integrated approach to employer sponsored pensions over a given time period.

#### *Capital transfers*

~~37.22~~37.23 It is also possible to construct FWTW tables on receipts and payments for the elements of capital transfers and their sub-components -- capital taxes, investment grants, and the various elements of other

capital transfers. The latter could include inter-sectoral details on compensation for extensive damages, exceptionally large insurance settlements from natural disasters, ~~calls on standardized guarantees~~, etc. (data confidentiality permitting).

## 5. Cross country tables

~~37.23~~37.24 Where ~~stock~~positions and/or transactions with non-residents can be broken down by country and sector, linkages across economies can be better followed. Global FWTW tables (sometimes referred to as global flow of funds analysis) with such detail could highlight the financial relationships across economies. As an example, many country analysts were interested in exposures to US banks during the financial crisis. The data limitations can be significant in developing such tables. See paragraphs 37.465 and 37.4764 for a further discussion on the potential to provide cross-country details on a FWTW-basis.

## 6. Quality considerations

~~37.24~~37.25 Analysis can be limited by the quality of the estimates on the various sectors, even in the case of aggregated FWTW-tables. For example, the split between the bond holdings of households (and NPISHs) and non-financial corporations in tables 37.1 and 37.2 above may be based on simple rules of thumb, due to gaps in the source data. In this case, the table may be less useful, although the table still accurately accounts for two-thirds of the holding of debt securities in the financial corporations, government, and non-resident sectors, respectively. Alternatively, households (and NPISHs) and non-financial corporations could be grouped together. On the other hand, it may be known with some degree of certainty that the remaining one-third is largely held by the households sector, so the allocation can be considered as reasonably accurate. In all cases, it is important to provide additional metadata on the quality aspects of the statistics presented.

~~37.25~~37.26 Accuracy issues should not necessarily preclude more disaggregated FWTW-tables. It is standard practice that compilers use whatever source data are available and ideally include them in the compilation of their financial accounts and balance sheets for institutional sectors, including underlying details such as the FWTW-information. If the source data show to be inadequate, or simply missing, for certain financial instruments, one may want to focus on certain financial instruments for which source data are considered of sufficient quality. The next section briefly discusses some source data that are important in the context of financial accounts and balance sheets, as well as for more disaggregated FWTW-data.

# C. Counterpart data and security-by-security databases

## 1. Introduction

~~37.26~~37.27 In the past, compilers relied more heavily on survey and information from regulators and umbrella organizations (e.g., investment fund institutes, central credit unions) and other information to compile the individual pieces of the institutional sector accounts. This resulted in a more than desirable reliance on residual derivation in sectors for which very limited or no direct source information was available. In recent decades various national agencies (e.g., financial institutions' regulator authorities) and international agencies have supported the need to improve the quality of the source data for compiling the institutional sector accounts. As an example, the development and increased availability in many countries of monetary and financial statistics as well as government finance statistics have helped complete and standardize financial reporting in many countries. All of these efforts have supported and strengthened statistics in the financial corporations' and general government sectors, both critical areas in the sector accounts, including additional details. In addition, there has been a great deal of development in external sector statistics in many countries, with respect to both instrument details and stock data.

~~37.27~~37.28 The availability and analytical usefulness of FWTW-tables is to a significant degree dependent on the availability of more detailed source data, including an increasing reliance on microdata on, for example, securities. The efforts by many statistical agencies and central banks, as well as by international organizations, over the years have been facilitated by the further development of databases and related

data infrastructure systems in the last decades. This has led to an expanded emphasis on source data on counterparty sectors and their microdata equivalence of security-by-security databases. In addition, one can observe an increasing availability of additional dimensions, such as the term structure and currency composition, for key financial instruments.

## 2. Data on counterparty sectors

<sup>37.28</sup><sup>37.29</sup> Data on counterparty sectors for a few financial instruments can be relatively straightforward. For example, certain types of government savings bonds can only be issued to households. Other counterparty data may come from supplementary information from deposit-taking financial institutions. For example, a deposit liability broken down by counterparty sector from banks may provide high quality FWTW-information on this financial instrument which can replace lower quality survey data on the holdings of deposits. This may also include a term structure for the deposits and a domestic-foreign currency split. Similarly, loan assets by counterparty sector from financial corporations may provide FWTW-information that is superior to the source data from issuers (debtors) and may also include term structure and currency composition.

<sup>37.29</sup><sup>37.30</sup> Security-by-security (SBS) data are compiled by many countries for use in the compilation of financial accounts and balance sheets. Data on new issues of debt and equity securities can be obtained from corporations supporting these markets, such as flotation corporations and exchanges, or from companies that compile and sell this information. Such databases include the new issues of securities, broken down by security, and they usually also include information on the terms and issue rates of the security, the redemption, the current value, the currency of issue, the security identifier number, and other details (sometimes the initial purchaser), etc. In the case of debt securities, this supplementary information can allow for the calculation of market values, revaluations and accrued interest. This high-quality information can replace survey data and provide the sub-instrument detail in FWTW-tables for issuers (liability side), such as currency, maturity and interest rate breakdowns.

<sup>37.30</sup><sup>37.31</sup> In some economies, compilers have been able to augment their SBS data by adding information on the asset side, by security, and matching it with the liability side information. Typically, compilers approach large institutional investors and custodians to obtain electronic data on holders' current values for the compilation of balance sheets, as well as purchases and sales of securities for the compilation of financial accounts from companies that facilitate these transactions such as brokers and exchanges or from companies that compile information on this activity. As with the liability side, this information often comes with additional details on the securities (e.g., security identifiers and currency). This is a more efficient process than trying to obtain this data via surveys, although the information might be collected under the auspices of a survey. Given the importance of securities in most economies, this type of database data is quite valuable to compilers and allows for the construction of very detailed FWTW-tables on securities to enhance their analytical potential (such as mentioned in paragraph 37.28).

<sup>37.31</sup><sup>37.32</sup> More detailed information on source data particularly relevant for the compilation of financial accounts and balance sheets, including relevant FWTW-information can be found in chapter 7 of the UN Handbook on Financial Production, Flows and Stocks in the System of National Accounts.

## D. Uses of FWTW-tables

### 1. Introduction

<sup>37.32</sup><sup>37.33</sup> More recently, there has been increased interest in financial accounts and balance sheets in terms of detecting spillover effects across institutional sectors, both in the domestic economy and abroad. The global financial crisis that began in 2007-08 gave prominence to the need for FWTW-tables as a supplement to the institutional sector accounts, with the need for more granular information on interlinkages between sector and countries in response to specific analytical issues. FWTW-tables can support a more detailed analysis of overall inter-sector relationships (e.g., between lenders and borrowers), in addition to a detailed representation of financing activities and portfolio shifts across sectors, and an enhanced analysis of selected instruments and related markets. Moreover, exposures and potential vulnerabilities may become evident from the information in the FWTW-tables, and the inter-sectoral relationships by instrument are now deemed essential to analyse and monitor. This type of analysis can also help prepare for adverse economic conditions in one sector or market that might rapidly spread to other sectors and markets and thus more broadly affect financial markets, sectors and the

economy at large. While in a contagion situation, the transmission effects can be traced with the help of FWTW-tables. In addition, in the case of a complete and fully integrated sequence of economic accounts, there is the potential to trace other types of spillover effects more fully (e.g., those that originate from supply or demand shocks, unanticipated price instability for commodities or financial instruments, etc.).

37.3337.34 This section discusses and illustrates some extensions of FWTW-tables and describes their applications. It is not intended to be exhaustive. In addition, it is important to note these derived tables can be customized and paired with other tables, to focus on specific aspects which are important for policy and analysis.

## 2. Analysis of exchange rate fluctuations and financial adjustments

37.3437.35 FWTW-tables on financial transactions, as recorded in the financial accounts, can highlight the transaction-based inter-relationships across the institutional sectors of the economy in a certain period of time. These tables provide, for a financial instrument, transactor details on the issuers of liabilities and counterpart holders of assets, including subsequent sales and purchases in these financial instruments, and thus illuminate the financing activity across institutional sectors. This information can also help assess the reactions of economic agents to different events and provide a leading indicator that can help shed light on the build-up of risk and potential spillover effects across sectors.

37.3537.36 It may be that in a particular period, there is an unusual swing in the exchange rate at the outset of a quarter with respect to a major foreign currency in use in the economy. In this example, it is assumed that there is an appreciation of the domestic currency over this foreign currency. A key question might be how economic agents (borrowers as well as lenders) in the economy react to this change. Some indication might be gleaned from a FWTW-table for total loans, however the foreign currency transactions would be partially masked by transactions in domestic currency (which could be partly offsetting). In fact, this demonstrates the need to incorporate currency details in these tables. In this case, it would be useful to construct both a domestic and foreign currency FWTW-table for loans, or to incorporate both in the same table. Table 37.3 presents a simplified example of a FWTW-table for foreign currency loans.

Table 37.3: FWTW-table for financial transactions in loans, foreign currency

HOLDERS→ ----- ISSUERS ↓	Resident non- financial corporations	Resident financial corporations	Resident general government	Resident households and NPISHs	Total economy*	Non- residents	Total All holders (matrix total)
Resident non- financial corporations, foreign currency	10	40	0	0	50	30	80
Resident financial corporations, foreign currency	0	-10	0	0	-10	20	10
Resident general government, foreign currency	0	10	0	0	10	0	10
Resident households and NPISHs, foreign currency	0	0	0	0	0	0	0
Total economy, foreign currency	10	40	0	0	50	50	100

Non-residents, foreign currency	0	0	0	0	0		0
Total All borrowers, foreign currency	10	40	0	0	50	50	100

\*Sum of resident sectors

37.3637.37 Table 37.3 suggests some developments in the quarter, likely related to the exchange rate fluctuation. First, there has been an increase in loan borrowing in foreign currency at the economy-wide level, concentrated in non-financial corporations which borrowed from financial corporations and non-residents. Second, financial corporations also raised funds in foreign currency but shifted borrowing toward non-residents (e.g., loans from non-resident corporations) with a reduction in borrowing from resident financial corporations. And third, non-residents supplied a full half of all new funds raised in foreign currency loans.

37.3737.38 This table could be supplemented by the term structure of those loans, which might shed some light on the short-term expectations around the exchange rate. Pairing this table with one on domestic loans would indicate whether total loans are up or down in the quarter or whether there was simply a shift towards foreign currency loans. Other financial instruments' foreign currency tables would add to the understanding of how economic agents in the economy more fully adjusted to the exchange rate movement. In particular, a FWTW-table on foreign currency and deposits, or a joint table on deposits and loans, would likely also yield useful information. In addition, for any of these tables it might be useful to include the subsector details for financial corporations, to arrive at a more complete picture of which of these types of institutional units accounted for borrowing abroad. Similarly, a time series presentation as well as corresponding balance sheet tables would add additional context to the adjustments in relation to the change in the exchange rate.

### 3. Analysis of a financial crisis

37.3837.39 Another example concerns the impact of a financial crisis for which the catalyst was largely a sustained and significant housing bubble and a related problem of overextended credit in a mortgage market in a large economy. An analysis of the mortgage market can be supplemented. For example, the issue of sub-par mortgages could be partially spread through the securitization of mortgages and the subsequent use of credit default swaps, with adverse effects on the economy. In relatively short order, the crisis could spread to other economies and take on different forms. Detailed FWTW-tables can shed some light in this context.

37.3937.40 To focus on one angle of such a crisis, it could be useful to not just monitor the growth in securitization but to also understand who was holding the potentially compromised mortgage-backed securities, how their stock positions changed over time, and whether the predominance of the activity was in long or short-term securities relative to the securitized assets. In other words, one may want to have available FWTW-tables for components of the debt securities included in tables 37.1 and 37.2, by breaking down short and longer-term asset-backed securities with as much sector detail as possible. This could have been paired with other FWTW-tables tied to the mortgage market and different instruments tied to liquidity (in the case of a credit crunch). In table 37.4, it is assumed that long-term asset-backed securities (ABS) are dominated by mortgage-backed securities (MBS). MBS may be available as a subcomponent of ABS. On the other hand, short-term securities may be dominated by personal loans (including credit cards) and other short-term loans as indicated by the asset composition of the issuing sector. In this case, the FWTW-table compares the issuers of ABS in the subsector other financial intermediaries, except insurance corporations and pension funds (S-125) to the holdings of ABS by term structure of the securities.

Table 37.4: FWTW-table for stockpositions in asset-backed debt securities, by term structure

STOCKS	T	T+1	T+2	...	T+n
Issued by: ABS units in other financial institutions intermediaries (S125), short-term	50	60	90		
Issued by: ABS units in other financial institutions intermediaries (S125), long-term	100	140	210		
Held by: Deposit-taking corporations (S122), short-term	10	10	15		
Held by: Deposit-taking corporations (S122), long-term	20	25	35		
Held by: MMFs (S123), short-term	2	7	7		
Held by: MMF (S1234), long-term	0	0	0		
Held by: NMMFs (S1243), short-term	0	0	0		
Held by: NMMF (S124), long-term	20	25	35		
Held by: Other financial intermediaries (S125), short-term	10	10	20		
Held by: Other financial intermediaries (S125), long-term	10	15	25		
Held by: Insurance corporations (S128), short-term	2	2	2		
Held by: Insurance corporations (S128), long-term	15	15	20		
Held by: Pension funds (S129), short-term	14	19	29		
Held by: Pension funds (S129), long-term	25	35	55		
Held by: General government (S134), short-term	0	0	0		
Held by: General government (S134), long-term	5	5	10		
Held by: Households (S14), short-term	2	2	2		
Held by: Households (S14), long-term	5	5	10		
Held by: Other domestic sectors, short-term	0	0	0		
Held by: Other domestic sectors, long-term	0	0	0		
Held by: Total economy*, short-term	40	50	75		
Held by: Total economy*, long-term	100	125	190		
Held by: Non-residents (S12), short-term	10	10	15		

Held by non-residents (S12), long-term		15	35		
Total All holdings, short-term	50	60	90		
Total All holdings, long-term	100	140	210		

\*Sum of resident sectors

37.4037.41 Table 37.4 suggests some interesting developments. Firstly, it shows a sharp increase in ABS outstanding over three time periods, with the bulk of the growth in long-term securities. What share of these new ABS is related to sub-par mortgages (future non-performing loans) is unknown, but it is likely that some of the problems in the mortgage market are reflected in the notable increase in ABS thus transmitting increased risk to investors. The table also shows that all investors have increased their holding of ABS. Pension funds more than doubled their investment, to become the largest domestic investor in ABS. Mutual funds had also increased their exposure, and it is possible that doubling of the holdings in S125 reflects issues of ABS securities that have not yet been picked up by other investors. Another possible interesting development shown in the table is the growth in short-term ABS, and the question of whether some of these are backed by longer-term assets (in this case securitized mortgages) leading to a maturity mismatch within the subsector. Lastly, non-residents have tripled their holdings of ABS, especially in the last quarter, possibly leading to a situation where some of the domestic mortgage market problems are transmitted abroad.

#### 4. Analysis of interest rate fluctuations on investment income

37.4137.42 For analytical purposes, the interest component of property income might be useful to focus on. For example, there can be a demand in following, during a period of interest rate fluctuations, the transactions in various interest-bearing instruments on both the expenditures and revenues sides in relation to the sectors/subsectors receiving and paying interest. In this case, one might be interested in FWTW-tables for interest transactions in deposits, loans and debt securities, possibly by term structure (one such split being between demand deposits and time deposits). Table 37.5 presents interest flows (receipts and payments) on deposits offered by domestic depository corporations, by sector, by type, and over time (assuming quarterly time periods). Such a table might be constructed in the event of a sharp increase in short-term interest rates in period t+2), which may or may not be sustained.

Table 37.5: FWTW-table for interest on deposits

STOCKS	T	T+1	T+2	...	T+n
Paid by: Deposit-taking corporations (S122), demand deposits	70	80	80		
Paid by: Deposit-taking corporations (S122), time deposits	100	109	113		
Received by: Financial corporations (S12), demand deposits	5	6	6		
Received by: Financial corporations (S12), time deposits	10	12	12		
Received by: General government (S134), demand deposits	5	7	7		
Received by: General government (S134), time deposits	0	0	0		
Received by: Households and NPISHs (S14 S15), demand deposits	40	44	44		
Held by: Households and NPISHs (S14 S15), time deposits	60	64	69		
Received by: Non-financial corporations (S11), demand deposits	10	12	12		

Received by: Non-financial corporations (S11), time deposits	20	22	22		
Received by: Total economy*, demand deposits	60	69	69		
Received by Total economy*, time deposits	70	98	101		
Received by: Non-residents (S±2), demand deposits	10	11	11		
Received by non-residents (S±2), term deposits	10	11	11		
<b>TotalAll-receipts, demand deposits</b>	70	80	80		
<b>TotalAll-receipts, term deposits</b>	100	109	113		

\*Sum of resident sectors

**37.4237.43** Table 37.5 shows deposit taking sectors increasing their interest payments in t+1<sub>2</sub>, reflected in higher receipts in almost all holders' subsectors. The limited increases in period t+2<sub>3</sub> suggest that the short-term rates remained at their higher level with some additional term deposits coming due and receiving a higher return. This analysis could be partnered with an accompanying FWTW-table on demand versus term deposits, in order to identify the role that any portfolio shifts may have played in the interest income changes.

**37.4337.44** More generally, a FWTW table for interest flows can be combined with a FWTW-tables on interest bearing instruments for different or all such instruments. The tables can then be combined to estimate the implicit yields in interest-bearing instruments (e.g., interest received by type of instrument over instrument holdings), though one may wish to add back the implicit financial services on loans and deposits component on deposits and loans for this exercise. The overall return on an instrument can be thought of as the property income and holding gains or losses. Holding gains/losses from the revaluation account can also be presented in a FWTW dimension. These might be used, by combining holding gains on debt and equity instruments with sector/subsector holdings to calculate a different type of implicit yield.

**37.4437.45** There are other examples of complementary FWTW-tables that can be used for purposes of policy and analysis. For example, FWTW-tables on financial stocks and flows can be analysed in conjunction with each other for an expanded perspective on financing and its effects. A detailed sequence of accumulation accounts FWTW table can also be constructed (for any given instrument or total instruments) that incorporates stocks and flows, including holding gains and volume changes, by sector of issuer (on the vertical scale) and sectors of holders (on the horizontal scale). There might also be an interest in analysing holding gains on financial instruments with taxes on holding gains.

## 5. Cross-country analysis

**37.4537.46** For any given financial instrument, with debt securities being the most likely candidate, it may be possible to construct a FWTW cross-country or global FWTW table, with varying degrees of detail. Table 37.6 displays the possibilities for countries A, B, C, and D, where good quality bilateral data allow for such a more detailed analysis. It may also be possible to include some or all of the sector details, by country, data sources permitting. Such a table would clearly show the global and sectoral interconnectivities related to this instrument. The IMF has undertaken related work with respect to certain financial instruments (e.g., the coordinated portfolio investment survey (CPIS)), and some of these are more likely to be able to be broken down by sector. There have also been proposals and initiatives with respect to international exchanges of data for securities (see IFC paper "The IMF balance sheet approach: towards from-whom-to-whom information on cross-border portfolio securities", 2018).

**Table 37.6: Financial instrument holdings and outstanding issues by country**

Holder/ issuer resident in	Holders, by sector Country A	Holders, by sector Country B	Holders, by sector Country C	Holders, by sector Country D	Holders, by sector Other countries	<b>TotalTOTAL All-holders</b>
----------------------------------	------------------------------------	------------------------------------	------------------------------------	------------------------------------	---	-----------------------------------

Issuers, by sector Country A						
Issuers, by sector Country B						
Issuers, by sector Country C						
Issuers, by sector Country D						
Issuers, by sector Other countries						
<b>Total</b> <b>all issuers</b>						

37.4637.47 More generally, it may be possible to construct a global FWTW-table across certain countries for the net international investment position (net IIP), assuming that some or all of the supporting key sub-instrument details and the required geographical data are available. The analysis can be enhanced for selected countries that have broken down their IIP assets and liabilities by institutional sector. Such a table would show how the sectors in these economies are related to each other, via the net international claims. However, the data demands are quite significant for such an endeavour, given that not all international assets and liabilities may be able to be readily broken down by sector and by geographical region. Nevertheless, such a table would be possible to be compiled for countries with good bilateral/multilateral data, supplemented by other sources of data and some degree of estimation.

## E. Related financial indicators

### 1. Introduction

37.4737.48 This section underlines the usefulness of a framework that can help assess the financial health of individual sectors and subsectors, and touches on some existing and newer approaches in this area. FWTW-information may add to the analytical usefulness of such indicators, by providing granular information that allows for the tracing of debtor-creditor relationships among institutional sectors.

### 2. The balance sheet approach to financial stability

37.4837.49 Interest in balance sheet data as a means to detect financial risks and vulnerabilities post-financial crisis is alluded to in the above. It is also evident in some of the updated data frameworks, including work undertaken at the IMF in the Monetary and Financial Statistics domain, that focusses on the assets and liabilities of financial corporations, and the IMF's Financial Soundness Indicators. This also concerns the Balance Sheet Approach to Financial Stability developed by the IMF (see IMF Working Paper, A Balance Sheet Approach to Financial Crisis, 2002; and Balance Sheet Analysis in Fund Surveillance, 2015), which is an analytical framework for understanding financial crises in emerging markets based on an examination of various financial asset and/or liability stock variables in the main sectors of the economy as well as for the balance sheet of the economy. This effort also applies to developed economies, many of which have made use of similar indicators for some time, but usually not as systematically as in the balance sheet approach. The approach basically augments the longer-standing analysis which mainly focused on flow variables (e.g., current account, fiscal balance) or on aggregated indicators.

37.4937.50 The balance sheet approach helps to highlight how balance sheet problems in one sector can spill over into other sectors. Sectoral balance sheets can help analysts evaluate the trade-offs between different policy objectives that arise after sectoral problems may have expanded into a systemic threat to the financial and economic system. Some financial crises occur from a gradual build-up of risk in certain sectors (endogenous factors), while others are precipitated or exacerbated by adjustments in portfolios from an initial shock (exogenous factors). In all cases, timely balance sheet statistics can help shed light

on potential vulnerabilities.

37.5037.51 Specifically, the balance sheet approach assesses the balance sheet of an economy's ~~major~~main sectors, for maturity, currency, capital structure mismatches and solvency issues. When such problems arise, these are not typically confined to the original sectors or instruments, and each can be further analysed in the context of specific FWTW tables. The following main mismatches can be distinguished:

- **Maturity mismatches** can occur in instances where there is a large gap that between liabilities due in the short term and liquid assets, which can leave a sector or subsector unable to meet its contractual commitments on debt. This can occur if the refinancing of short-term debt is problematic, such as temporarily not possible or demands a higher return for the refinancing. This is also known more broadly as liquidity risk. FWTW tables can identify the potentially vulnerable counterparty holders of the short-term debt.
- **Currency mismatches** can occur in a situation where liabilities are primarily denominated in foreign currency, but financial assets are largely in domestic currency. This can create an ongoing problem in terms of principal and interest payments on debt, which can be exacerbated by a domestic exchange rate depreciation. Alternatively, there can be a situation where financial assets are largely stated in foreign currency relative to assets, then a capital loss can occur if the foreign currency depreciates relative to the domestic currency resulting in a different type of potential debt service issue. FWTW-tables on foreign debt (e.g., loans and securities) can shed light on the counterparties at risk.
- **Capital structure issues** cover instances where there is a relatively heavy reliance on debt (e.g., in the non-financial corporations' sector) as opposed to equity financing, which can result in a situation that is untenable in the face of a sharp or sustained drop in income. This is also referred to as assessing a firm's leverage and is measured by its debt-to-equity ratio. In such a scenario, FWTW-tables can display the counterparties that are exposed to the debt.
- **Solvency issues** cover instances where current financial assets and expected future revenue streams are insufficient to cover the liabilities, including any contingent liabilities. This situation can occur due to sustained weak income performance and/or a gradual build-up of debt, or it can arise in conjunction with some of the other situations described above.

37.5137.52 The analysis above can be augmented by combining key indicators related to currency and maturity characteristics for relevant financial instruments, such as deposits, loans, and debt securities in FWTW-tables. As one example, a FWTW-table for stocks of debt securities (such as table 37.1) of resident issuers and holders, by sector, as well as the rest of the world, with currency and maturity details might be possible to construct for some countries. As another example, a FWTW-table could be constructed for stocks of foreign debt securities with currency and maturity details for resident holders by institutional sector relying mainly on data from the Coordinated Portfolio Investment Statistics (CPIS). At the limit, it might be possible to extend table 37.6 to add maturity and currency details for select countries and instruments, provided that quality bilateral data are available.

### 3. Some other financial indicators

37.5237.53 There are indicators which may complement the balance sheet approach discussed above and can be extended beyond financial and non-financial corporations sectors.

- **For corporations**, expanding on maturity mismatches, a *current ratio* can be calculated as short-term assets to short-term liabilities, as a measure of the ability meeting current obligations. This measure usually excludes receivables and payables and can also exclude inventories. *Tobin's Q* can be calculated as the ratio of the market value of equity to its own funds at book value and it is indicative of any premium or discount that investors have assigned to corporate shares.
- **For any given sector**, the leverage calculation can be applied as liabilities relative to net worth or financial net worth.
- **For all sectors of for the economy**, a further liquidity indicator that can be used in all sectors is the ratio of short-term to long-term debt, which is used to assess the degree of, and possible risk associated with, a sustained shift towards shorter-term debt. The composition, and changes in the composition, of assets-liabilities by institutional sector and subsector is important for monitoring

structural changes and preferences with respect to liquidity and risk. As a more detailed supplement to this exercise, FWTW-tables as presented in tables 37.1 and 37.2, can also be compiled in percentage form for any given financial instrument.

~~37.53~~37.54 There are also a series of ratios that use balance sheet and other data to measure and monitor issues associated with financial stability.

- **For corporations**, the *performance ratio* is the measure of saving or undistributed earnings to equity (own funds at book value), which compares earnings to shareholders' investment. For non-financial corporations the *return ratio* compares net operating surplus to non-financial assets.
- **For all sectors**, the ratio of interest (and possibly principal) payments to debt - *the debt service ratio* - is a useful supplement to leverage measures. The *internal to external sources of funds ratio* provides an indication of the funds borrowed or raised externally to saving or sales of financial assets. The ratio of saving or net lending to GDP/GNI is a broad indication of the sector's role in providing funds for its own financing or for other sectors of the economy. All of these indicators can change significantly during periods of economic stress.
- **For general government** gross ~~or net~~ debt to GDP/GNI ratios have been in use for a long time for various purposes (e.g., debt sustainability, the ability for fiscal stimulus, etc.). Here, one may also consider ratios based on gross debt adjusted for certain financial assets owned by government. These measures can be enhanced by further breakdowns of debt in selected FWTW-tables.

## Chapter 38: Thematic and Extended Accounts

### A. Introduction

- 38.1 The integrated framework of the SNA is a fully integrated and internally coherent system, and it provides a relatively limited amount of disaggregation in order to present an uncluttered view of the major macroeconomic aggregates. Yet answering the broad range of relevant questions about economic activity and phenomena often requires multiple perspectives and the sort of detailed disaggregation that would overburden the integrated framework of economic accounts. Demands therefore frequently arise for further data that will permit deeper insight into economic activities or phenomena of special interest or importance and show the broader context.
- 38.2 Thematic and extended accounts (formerly known as satellite accounts) are flexible tools for increasing the visibility of key phenomena by bringing all the pertinent data together in one place, and by presenting further disaggregation, alternative aggregations and approaches, and broader context while maintaining coherence with the overall conceptual framework of the SNA. They can also be a place where experimental methods are tested. Complementary and experimental data may also be presented in a supplementary table or account rather than a fully elaborated thematic or extended account in cases of topics that can be covered in a single table or account of limited scope. The positions of supplementary tables or accounts, thematic accounts and extended accounts in the taxonomy of SNA accounts are shown in chapter 21, Box 4.
- 38.3 Thematic and extended accounts are linked to, but distinct from, the integrated framework of economic accounts. Their links to the integrated framework enable thematic and extended accounts to inherit the rigour of the SNA, including its definitions for concepts such as production, consumption, income, and assets, and its framework for ensuring the consistency of the estimates with each other and with higher level aggregates. For example, as part of ensuring this consistency, compilation of a thematic account may include balancing the supply and use of the products included in the key activity of interest. The link to the integrated framework also allows these accounts to show the economic significance of the items they cover through meaningful comparisons to macroeconomic aggregates such as GDP/NDP, gross value added, and trade in services.
- 38.4 One of the strengths of the SNA is its flexibility, and this flexibility extends to the choice of topics for thematic or extended accounts. The economy's structure and growth pattern, the key policy issues, and data availability are factors to consider in identifying the themes that would be appropriate to cover in a thematic or extended account. Nevertheless, the compilation of certain thematic or extended accounts is encouraged to fill important information gaps on aspects of well-being and sustainability. These include: (i) the labor account (discussed in chapter 16), (ii) the thematic account on the digital economy (discussed in chapter 22), and (iii) the extended accounts on household unpaid service work, health, and education and human capital (discussed in chapter 34). In addition, tables analyzing inequality by disaggregating household income, consumption, and wealth (discussed in chapter 32) are part of the recommended data dissemination on the household sector.
- 38.5 This chapter explains the roles of thematic accounts and extended accounts in dissemination of macroeconomic statistics and provides general guidelines for compiling a thematic account. The purposes and scope of thematic and extended accounts are explained in Section B. Section C provides an overview of the main tools for developing a thematic account, including supply and use tables. Section D explains the steps in developing a thematic account on a key activity in the framework of supply and use tables, which include disaggregation of the relevant elements of the supply and use tables, complementing the information provided in those tables with physical indicators, and, possibly, extending the production boundary to bring visibility to goods and services produced for own consumption. This section concludes with a discussion of the conditions that allow compilation of the measures derived further down in the sequence of economic accounts on institutional sectors, which include the income, saving, investment flows, and balance sheet of the key activity.

## B. Relation between Thematic Accounts and Extended Accounts

- 38.6 Both thematic and extended accounts provide complementary data that allow insight into a key activity or aspect of the economy that lacks visibility in the integrated framework of economic accounts, but they differ in their relationship to those accounts. Thematic accounts disaggregate and rearrange the items in the integrated framework of the SNA, while extended accounts expand, or look beyond, the standard SNA boundaries to give a different perspective or a more comprehensive view of a phenomenon and its broader context. However, to provide the full picture or the broader context, it may be necessary to add items beyond the standard SNA boundaries to a thematic account, and it is common to include items providing further detail on measures in the standard sequence of accounts as part of an extended account. Whether an account containing both thematic account and extended account elements is considered a thematic account or an extended account is determined by its focus. If, for example, measures of imputed monetary values of services or externalities beyond the SNA production boundary are the focus, the account is typically referred to as an extended account. This also holds if the focus is on measures that extend the asset boundary.

### *Thematic accounts*

- 38.7 Analytically important items for understanding the key activity or phenomenon that is the focus of a thematic account are often invisible in the integrated framework of economic accounts because they are subsumed in broader aggregates or are implicit components of transactions estimated at a higher level of aggregation. Thematic accounts increase the visibility of such items by compiling more granular decompositions and by compiling alternative aggregations that summarize the relevant granular data. These alternative aggregations may, for example, introduce a different treatment of ancillary activities in which the elements of the standard framework of economic accounts are rearranged without altering the boundaries of the underlying SNA concepts.
- 38.8 Most thematic accounts cover a key activity, which is an activity that is of high economic importance or of special interest for policymaking or other purposes. To provide a complete view, the key activity must often be defined broadly enough to include segments of several of the industries defined in the classification system used for the standard supply and use tables (such as ISIC rev. 5). The boundary of the key activity may therefore encompass detailed industries or industry segments from different sections and divisions of the standard classification system, in effect rearranging that system. A thematic account may also analyze a key phenomenon covered by the standard framework of economic accounts in more detail by providing additional breakdowns and alternative aggregations. Information on other related activities may also be provided as part of showing the impact or broader context of the key activity or phenomenon – for example, a thematic account on the digital economy may provide information on the producers that use digital intermediation platforms to sell their (non-digital) output.
- 38.9 Tourism accounts are an example of widely compiled thematic account. Accounts for health and education (discussed in chapter 34) are also widely compiled either as thematic accounts or extended accounts. Other common topics for thematic accounts are agriculture, culture, sports and recreation, transport, and social protection. Finally, the profound impact of digitalization has made the digital economy a frequent theme for the work on new types of thematic accounts; see chapter 22 for a discussion of these accounts.

### *Extended accounts*

- 38.10 A different perspective or a more comprehensive view can provide important context for the standard SNA indicators, and cover aspects of, for example, well-being and sustainability and of production, income and wealth that are beyond the scope of the standard framework of economic accounts. Extended accounts present concepts that expand or modify the standard boundaries of production, consumption, investment, income, assets, and wealth, and indicators that concern phenomena beyond these boundaries. Measuring these concepts could involve the use of experimental methodologies.
- 38.11 Extended accounts often include imputed values for indicators measured in monetary units and/or non-monetary indicators measured in physical units. Expanding an SNA boundary usually requires imputing a monetary value for goods, services, or assets that are not sold in markets, or estimating a monetary value for

externalities. This imputation may, for example, be based on actual or inferred costs of production, observed market prices of related products, the net present value of expected future returns, or the value of the harm to health or the environment caused by an externality.

- 38.12 Areas in which extended accounts can fill information gaps include unpaid household service work, education and human capital, health, and free digital services. Unpaid household service work, including volunteering, is a frequent theme for an extended account (see chapter 34). Extended accounts for education and human capital may also expand the production boundary to include unpaid household production of educational services and expand the asset boundary to include income-based and cost-based measures of human capital (see chapter 34). Similarly, the extended account on health care may expand the production boundary to include unpaid household production of health care and long-term social care (see chapter 34). Finally, an extended account could impute direct household consumption of free services of digital platform (see chapter 22).
- 38.13 Although monetary measures of stocks and depletion of natural resources are included in the SNA, addressing concerns about sustainability is another area where complementary systems provide a multitude of additional data. The System of Environmental-Economic Accounting (SEEA) provides two related sets of statistical standards to guide the collection, organization, and presentation of the data needed for the analysis of environmental aspects of sustainability. First, the *SEEA 2012 Central Framework* provides a framework for producing environmental-economic accounts in physical and monetary units on natural resource stocks and flows, natural resource inputs to the economy and on impacts of the economy on the environment and expenditures to mitigate these impacts. Second, *SEEA—Ecosystem Accounting* extends the SNA asset and production boundaries to recognize and account for ecosystem assets and the services derived from these assets in physical and monetary terms. The close relationship of the SEEA to the SNA and the use of its key components to assess sustainability are discussed in chapter 35.
- 38.14 When an extended account expands or modifies the SNA boundaries of production, consumption, or assets, it must remain internally consistent. Therefore, expanded definitions of production, income, and expenditures must maintain the accounting identities between production and income from production and between total supply and total use of a product. Furthermore, the terminology used in the extended account should clearly distinguish the alternative and expanded concepts from the standard SNA concepts.

## **C. Tools for Developing a Thematic Account**

- 38.15 Combining the data from the integrated framework of economic accounts with more detailed data from the supply and use tables and from outside sources will enable deeper insight into the key activity or phenomenon being analyzed in the thematic account. In addition, alternative aggregations based on alternative approaches to classification can aid in the analysis of the key activity or phenomenon. One of the steps in planning and designing a thematic account should therefore be to identify the outside data sources and alternative classifications that can help enhance the scope or depth of the analysis of the key activity or phenomenon of interest.
- 38.16 This section discusses commonly used resources for compiling a thematic account on a key activity. Supply and use tables are considered first, as they are typically used as a starting point for having more detailed breakdowns and can provide an organizing framework for the data. Outside data sources are discussed next. Last, this section discusses the use of alternative approaches for classifying and aggregating the data used to compile a thematic account.

### **1. Supply and Use Tables**

- 38.17 Although disaggregation of the production and generation of earned income accounts of the relevant institutional sector (or sectors) can provide valuable insights into the key activity featured in a thematic account, the organizing framework and wealth of information provided by supply and use tables (discussed in chapter 15) will allow a much more complete and comprehensive description of the theme being addressed. For example, data on who consumes the sector's output can be provided by drawing on the information presented in the use table. Furthermore, the key sector's linkages with the rest of the economy can also be

derived from the use table and used to estimate the indirect impact of an increase in its output of goods and services. Compiling the thematic account in the framework of supply and use tables will also help ensure its accuracy and its consistency with the rest of the accounts. (An example of deriving data that can be used to compile a thematic account by breaking out digital transactions, products and industries in extended supply and use tables is discussed in chapter 22, section F.)

- 38.18 As illustrated in the simplified example of extending the supply and use tables discussed in section D below, a supply table breaks out the domestic sources of supply of every product by industry. Its columns contain industries, and its rows contain products, with an industry's output of a product valued at basic prices. The supply table also contains columns showing imports, taxes less subsidies on products, trade and transport margins, and the total supply of each product at purchaser's prices. The total supply of a product at purchaser's prices is conceptually identical to the total of the uses of the product, and a process of balancing the supply and use tables ensures that this identity is satisfied in practice.
- 38.19 The use table breaks out each industry's intermediate consumption of a product, with additional columns showing the final consumption expenditures on the various products broken out by each institutional sector, gross capital formation, exports, and the total uses of the product. The bottom section of the use table shows industries' total intermediate consumption, value added and output, along with a decomposition of value added that includes compensation of employees, other taxes less subsidies on production, consumption of fixed capital, gross and net operating surplus, and gross and net mixed income. Additional rows show total output, labor inputs as measured by hours worked, and gross fixed capital formation.

## 2. **Alternative Aggregations**

- 38.20 Alternative aggregations are a key tool for analyzing a phenomenon or activity that lacks visibility in the standard system of accounts. In an alternative aggregation, the items contained in the standard aggregates are reclassified in a way that brings the key phenomenon or activity into focus. The rows and columns of the supply and use tables follow the standard product and industry classifications (CPC version 2.1 and ISIC rev. 5) at similar levels of their respective hierarchies. It can be quite instructive to bring together a set of detailed expenditures with a common purpose, or a set of detailed activities involved in the production of a key type of product. For example, if the objective is to analyze the impact of oil and natural gas on the economy, the thematic account may contain the industries of extraction of crude petroleum and natural gas (ISIC division 06), manufacture of refined petroleum products (ISIC class 1920), transport via pipelines (ISIC class 4930), wholesale of solid, liquid and gaseous fuels and related products (ISIC class 4671) and retail sale of automobile fuel (ISIC class 4730). Depending on local circumstances, it may also be useful to include petrochemical processing.
- 38.21 Many thematic accounts group together a select set of detailed industries of special interest or importance to the economy. Such special groups of selected industries are commonly referred to as a "key activity", "key sector", or just "sector". (However, this use of the term "sector" can cause confusion, as "sector" is typically used as a way of referring to an institutional sector in the SNA.) For example, a key activity containing the industries with critical roles in the economy's external transactions might be useful to track. Another example of a key activity is the group of industries that produce, transport, and sell oil and gas products discussed above.
- 38.22 The detailed industries and products that are grouped together to form a key activity often come from different sections of the standard industry classification and standard product classification. For example, a special aggregation might be developed to allow insight into an emerging new technology or business model that cuts across the standard industry or product boundaries. The key activity might be narrowly specified, such as a particular agricultural crop or mineral, or it might be relatively broad, such as all the goods and services primarily serving tourism. In either case, special supply and use tables may be compiled that concentrate on the key activity and summarize the other industries or products in broadly defined aggregates. If the key activity comprises a discrete set of enterprises for which income statement and balance sheet data are available (discussed below in paragraph 38.43), a complete sequence of economic accounts for the key activity may also be compiled.
- 38.23 Classifications based on the purpose of the expenditure can also be used for the alternative aggregations.

Detailed expenditures identified as having a common purpose in the four functional classifications of the SNA (see Annex X on functional classifications), may be reassembled into cross-cutting aggregates of analytical interest. For example, the SNA functional classifications identify the expenditures on education incurred by households, government, nonprofit institutions serving households and market producers that could be part of a cost-based measure of human capital. A reclassification of the goods identified as durables in the Classification of Individual Consumption by Purpose (COICOP) as gross capital formation is another example.

- 38.24 A thematic (or extended) account may provide more than one type of alternative aggregation. The classifications that define the alternative aggregations of products, activities or transactions may be based on any of five dimensions: (i) the purpose of the expenditure; (ii) the characteristics of the product; (iii) who the user of the good or service is (e.g., resident and non-resident visitors in a tourism account); (iv) who the producer is (e.g., household non-market producers or informal unincorporated household market enterprises); or (v) the characteristics of the transaction (e.g., digitally ordered). Special aggregations of products in a key activity thematic account may include relevant secondary or ancillary outputs of industries whose primary product is out-of-scope.

### **3. Additional Source Data**

- 38.25 Constructing the relevant aggregates for the key activity that is the focus of the thematic account often requires further decomposition of the industries and products shown in the standard supply and use tables. Additional source data, such as an economic census or government or companies' administrative records or private data on electronic transactions, may be consulted to develop these further breakdowns. When drawing on alternative data sources, the differences in coverage, timing, and estimation methods between the additional source data and the integrated set of data in the supply and use tables must be taken into account. Supply and use tables often incorporate adjustments to ensure exhaustiveness (such as adding an estimate of the informal activity), to correct for differences in timing, and to balance the supply and use of the product.

## **D. Developing a Thematic Account on a Key Activity**

- 38.26 Most thematic accounts concern a key activity. An organizing framework based on supply and use tables will help ensure that the thematic account on the key activity is consistent with the standard framework of economic accounts and provides a complete analysis of the key activity. Compiling a thematic account in a supply and use table framework involves a series of steps. These steps disaggregate the relevant elements of the supply and use tables, develop complementary indicators giving additional perspectives on the key activity, and add information on the broader context by expanding the standard production and asset boundaries. In some cases, it may also be possible to add information on revenues and expenditures beyond those arising from transactions in goods and services, and on financial assets and liabilities.
- 38.27 The process of developing a thematic account on a key activity can be divided into a planning phase and a compilation phase. This section first discusses the planning phase. It then discusses the steps to compile a thematic account on a key activity drawing on the standard supply and use tables in combination with other source data. Although a complete analysis of the key activity would include all the steps and indicators described in this section, in some cases the circumstances may not call for all of them to be included to enable the users of the thematic account to understand the role of the key activity in the domestic economy and analyze the policymaking concerns related to the key activity.
- 38.28 Additional information on compiling certain specific types of thematic accounts or the items that go into these accounts can be found in specialized handbooks and manuals such as, for example, the international handbooks on accounts on tourism (see [Tourism Satellite Accounts: Recommended Methodological Framework 2008](#), United Nations et al., 2010), and on nonprofit institutions and volunteering (see [Satellite Account on Non-profit and Related Institutions and Volunteer Work](#), (United Nations, 2018). Other examples of compilation guidance on specific themes are the [OECD Handbook on Compiling Digital Supply and Use Tables](#) and the [OECD Handbook on Measuring the Space Economy](#).

## **1. The Planning Phase: Defining What is to be Measured**

- 38.29 Developing a precise definition of what is to be measured before beginning the compilation process will help guide the compilation process and help avoid inconsistencies and omissions. A precise definition of the measurement objective can also clarify the interpretation of the results. If the thematic account concerns a key activity, the boundary of the key activity must therefore be specified precisely enough to guide the data gathering and compilation processes. If left undefined, questions can easily arise about the boundary of a key activity that brings together detailed industries and products from different parts of the standard classification system.

## **2. Steps to Compile Thematic Supply and Use Tables, with Transport as an Example**

- 38.30 Compiling a complete thematic account for a key activity in a framework of supply and use tables requires steps to further disaggregate the relevant elements of these tables and steps to complement the information they provide with other monetary or physical indicators. For example, the further disaggregation in a thematic account on transport might distinguish different modes of transport, different types of passengers and freight, and public and private transport, and analyze physical indicators of cargo and passengers transported and of transport industry employment. It may also be appropriate to further complement the data in the supply and use tables with measures that extend the production boundary or account for environmental externalities. (As noted above, a thematic account can contain extended measures provided as supplementary information.)

### **Disaggregating the Relevant Elements of the Supply and Use Tables**

- 38.31 The first series of steps in compiling a thematic account based on supply and use tables involves disaggregation. Items in the supply and use tables must be disaggregated as required to analyze the detailed components of the key activity and to allow construction of aggregate measures composed of the detailed industries (or detailed products) included in the key activity. In addition to using the disaggregated data to present further analytical detail, aggregate measures of the key activity that combine the relevant detailed industries or detailed products, including those that require disaggregation to identify, should be compiled.
- 38.32 The disaggregated information on items in the supply and use tables should include further breakouts of the relevant (i) industries, (ii) products, (iii) taxes and subsidies on products, and (iv) components of value added. Taking breakouts that could be included in a transport account as examples, the decompositions of the relevant elements of the standard supply and use tables needed to analyze the key activity may be compiled as follows:
- i. Identify the industry columns of the supply and use tables that are within the bounds, or partly within the bounds, of the key activity and disaggregate these columns as needed for expositional and analytical purposes. For example, in the case of a transport account, the breakouts might distinguish public and private suppliers of land transport, passenger transport, and other services. In cases of columns that straddle the boundary of the key activity, the detailed industries that are within the scope of the key activity must be distinguished from the other detailed industries with which they have been combined so that the in-scope components can be included in the aggregated measures of the key activity, such as measures of its scale.
  - ii. Disaggregate the rows of the supply and use tables that cover the key products produced by, or used in, the key activity, including the relevant parts of rows that straddle the product boundary of the key activity. In a transport account, the detailed products might include the different modes of transport of passengers and freight. The disaggregation of the supply and use of a product might also distinguish different types of buyers (e.g., foreign and domestic air travel passengers) or types of transactions (e.g., the digital transactions of the digital economy thematic account).
  - iii. Break out the taxes and subsidies on the relevant products. The use table measures the uses of products at purchaser's prices, which include taxes on products and exclude subsidies on products, while the supply table measures industry output at basic prices, which include subsidies on products and exclude taxes on products. Breakouts of the taxes embedded in the relevant rows of the use table and the subsidies embedded in the relevant rows of the supply table can be quite instructive in cases

of products that are highly taxed or highly subsidized. In a transport account, for example, the subsidies on public transport and the taxes on different fuels may be substantial.

- iv. For the industries included in the key activity, compile further breakouts of value added. The standard use table decomposes value added into (i) compensation of employees, (ii) other taxes less subsidies on production and imports, (iii) consumption of fixed capital and depletion, (iv) net operating surplus, and (v) net mixed income. A further decomposition of value added might include a split of compensation of employees into wages and salaries and social contributions as a way of identifying industries where low social contributions reflect a predominance of informal employment. In the case of a transport account, a further breakout of other taxes less subsidies on production may reveal important sources of government revenue from taxes on land and structures, taxes on the use of equipment, and licensing fees.

### **Introducing Complementary Indicators**

- 38.33 The next steps are to complement the measures presented in the standard or disaggregated supply and use tables with indicators that provide additional detail or context. The first set of indicators to compile includes the gross and net fixed capital formation and the closing stocks of fixed capital of the establishments included in the key activity. Second, physical indicators of production and consumption that help analyze the performance and condition of the industries that make up the key activity should be compiled. For example, a transport account might report physical data on passenger-kilometers and freight tonnage in conjunction with monetary data on these services. The data on values at current prices may also be complemented with price and volume data. Comparing the growth of the totals of physical quantities with the growth of a comparable volume index calculated by deflating with a price index will allow insight into the change in the mix of services being supplied – for example, a shift towards higher-priced routes (e.g., due to improved quality) would increase the relative growth rate of the volume index for freight transport services.
- 38.34 Third, the complementary indicators of employment needed to analyze the key sector's impact on labour should be compiled. The labour indicators could disaggregate the data on hours worked in the bottom section of the use table by detailed industry and provide totals for the key activity and the suppliers of the products it uses. The data in the use table on compensation of employees and hours worked can also be complemented with data on the number of jobs or the size of the workforce employed in the key activity. For example, the usefulness of an account on transport might be enhanced by adding data on the composition of workforce employed in transport activities by occupation and gender or by the type of employment arrangement, including work intermediated by a digital platform.
- 38.35 The indicators of production may also be complemented by physical indicators of the environmental impacts of the key activity, such as quantities of pollutants and greenhouse gases emitted. For example, a transport account could include complementary indicators on the emissions generated by transport activities of enterprises and households.

## **3. Extending the Account beyond the Standard Production Boundary**

### **Alternative Treatments of Own-Account Production of Services**

- 38.36 The scope of the thematic account may be expanded to include measures that extend the production boundary in ways that add context and help give a complete picture of the key activity. One such extension is to include the relevant goods and services produced and consumed within the same establishment in expanded measures of the output and intermediate consumption of the key activity. This may include ancillary activities undertaken in the establishment where the output is used, which are not recorded in the integrated framework of the SNA (paragraph 6.41), Recording the production and intermediation consumption of an output by the same establishment, as well as the recording of production and intermediate consumption associated with ancillary activities, has no effect on value added but it brings visibility to previously invisible internal production. For example, in a transport account, the operating cost of trucks owned by enterprises in non-transportation industries might be used to measure in-house production of transport services.
- 38.37 A further step in extending the production boundary is to bring the relevant unpaid services produced by

households for their own consumption into an expanded measure of the output of the key activity. Household final consumption expenditures will then include the imputed value of the services produced by households for their own consumption and exclude households' expenditures on items used in producing these services either as intermediate inputs or for fixed capital formation (e.g., motor fuel and motor vehicles bought by households in the case of an account on transport). The value added from the households' production of own-account services can also be decomposed. For example, in the case of a transport account these components will be: (i) net mixed income equal to the imputed value of households' time spent in producing transportation services for own consumption, (ii) consumption of fixed capital reflecting the depreciation of the vehicles used in this activity, and (iii) the taxes on production associated with the vehicles (which are included in other current taxes paid by households in accounts based on the standard production boundary).

## Bringing Visibility to Externalities

- 38.38 Externalities are impacts of the actions of a unit on the condition or circumstances of third parties that occur without those parties' consent. Although these impacts can be either positive or negative, externalities from production that significantly affect households' wellbeing or sustainability are usually negative. As discussed in Chapter 2, Section B.4, the relationship between aspects of wellbeing affected by externalities and accounting-based data such as the integrated framework of the SNA or the SEEA is complex and involves issues of measurement boundaries, indirect effects of externalities that are captured in the integrated framework of economic accounts, and valuation concepts. In the case of environmental externalities, the SEEA Ecosystem Accounting Chapter 12 (section 12.2.3) provides some examples of alternative presentations, including one in which the costs associated with the external effects are attributing to the causing unit. Such alternative presentations could bring visibility to selected externalities – in the standard framework of economic accounts, externalities are not attributed to “causing” units and their direct impacts on the affected units are not recorded.

## 4. A simplified illustration of extending the supply and use tables

- 38.39 Tables 38.1–38.3 present a simplified example of extending the supply and use tables to record own-account services of enterprises and households. The starting point for the example is the standard set of supply and use tables in Table 38.1. The standard supply table shows that the economy produces apples valued at 35 at basic prices and imports apples valued at 20, and that trade margins and taxes on products raise the value at purchaser's prices of the total supply of apples to 75. The economy also produces motor fuel of 34 valued at purchaser's prices, motor vehicles of 40 valued at purchaser's prices, wholesale and retail trade margin services of 54, and transport services of 24. The use table shows that apple growers use motor fuel of 2 and transport services of 3, and that apples of 30 are used in the apple cider manufacturing industry. Another activity included in the manufacturing column refines imported crude petroleum of 18 into motor fuel, and a third manufacturing activity uses imported vehicles parts of 20 to produce motor vehicles. The manufacturing activities also use motor fuel of 5 and transport services of 6. The trade industry uses transport services of 15, and households use apples of 45, apple cider of 72, motor fuel of 12, and motor vehicles of 20 for final consumption. Motor vehicles of 20 are also used by domestic industries for gross fixed capital formation.
- 38.40 Table 38.2 extends the supply and use tables to include transport services produced and used internally by establishments in the agriculture and manufacturing industries. Recording the output and intermediate consumption of internally produced transport services increases the economy's output and the total intermediate consumption of transport services by 6 but does not change any industry's value added.
- 38.41 Table 38.3 further extends the production boundary to include the transport services that households produce for their own use. The imputed value of the transport services produced by households for their own consumption is 30. However, the value added of the transport industry and overall final uses only increase by 18. A change in the classification household expenditure of 12 on motor fuel from final consumption to intermediate consumption of the expanded transport industry partially offsets the impact of the additional output and final consumption of transport services of 30. The composition of final expenditures also changes, with a reduction of 2 in final consumption caused in part by the reclassification of household expenditures motor vehicles from final consumption and to gross fixed capital formation and an increase in gross fixed

capital formation of 20. The extended use table also includes a decomposition of the value added of households' own-account transport activity. Taxes on the use of motor vehicles of 4 and depreciation of the motor vehicles of 8 leave only 6 for the net mixed income generated by the transport activity.

- 38.42 To simplify Tables 38.1-38.3, motor vehicle maintenance and repair services are not included in these tables. However, in a more realistic example of bringing transport services produced by households for their own consumption inside the production boundary, there would also be a change in the treatment of household expenditures on motor vehicle maintenance and repair services from final consumption to intermediate consumption, in the same way as households' use of motor fuel shifts from final consumption to intermediate consumption in Table 38.3. The intermediate consumption of maintenance and repair services would reduce the value added of households' own-account transport activity and the mixed income from this activity. The change in treatment of maintenance and repair services would also reduce final consumption expenditures.

## **5. Adding an Analysis of Income and Finance**

- 38.43 The standard sequence of economic accounts for institutional sectors begins with the production and generation of income accounts, then proceeds to present a series of accounts that analyze revenues and expenditures, changes in assets and liabilities, and stocks of assets and liabilities. If the main items in this series of economic accounts are feasible to calculate, they will provide important insights into the performance and financial condition of the key activity. Among these items are property income receipts and payments, balance of earned incomes, current transfers, including taxes on income and wealth, saving, as well as analytical breakdowns of (the changes in) the stocks of assets and liabilities. However, the feasibility of compiling these items depends on how the key activity is organized.
- 38.44 Production and the related transactions covered by the supply and use tables are undertaken by establishments. In contrast, the accounts that analyze income flows and the changes in, and stocks of, assets and liabilities concern transactions that are undertaken by institutional units, which are enterprises in the case of a key activity. Enterprises can comprise multiple establishments, and data on enterprises often combine multiple establishments. If the establishments involved in the key activity belong to enterprises that do not have significant other establishments engaged in different activities, the transactions and balance sheet of those enterprises can be linked to the key activity and a complete sequence of economic accounts for the key activity can be compiled. However, if the enterprises involved in the key activity also have significant establishments engaged in other activities, the enterprises' transactions and balance sheet cannot be treated as coming just from the key activity. In this case, the income flows and (changes in) assets and liabilities of the key activity cannot be measured.

**Table 38.1 The Standard Supply and Use Tables**

*Supply table*

		Output by domestic industry					Imports	Trade and transport margins	Taxes less subsidies on products	Total supply
		Agriculture	Manufacturing	Trade	Transport	Total				
Supply by product	Apples	35				35	20	15	5	75

## Chapter 39: (2025 SNA)/Chapter 18 (BPM7) Informal economy (moved downwards, revised title)

(OLD Chapter 25: Informal aspects of the economy)

[Sections or paragraphs marked (\*) are SNA-only text and excluded from BPM7;

Sections or paragraphs marked (x) are BPM7-only text and excluded from SNA]

### A. Introduction

- 39.1 The informal economy provides employment and income to many people who might otherwise be unemployed. Informal workers and enterprises tend to be vulnerable to negative economic shocks, which has consequences for inequality and poverty. Measuring the informal economy is important for designing, implementing, monitoring and analyzing macroeconomic and social policies. The measurement framework for the informal economy aims to ensure consistent measures of informal production and informal labour inputs. Data compiled according to this framework are designed to inform policy decisions that may decrease the vulnerability of informal workers and enterprises, especially in developing economies.
- 39.2 The informal economy refers to the productive activities carried out by persons or economic units that are not covered by formal arrangements established by regulations and laws, such as registration, regulation, payment of taxes, and coverage of workers by social security and other labour laws and regulations. The informal economy includes all informal productive activities carried within the general production boundary. Compiling statistics on the informal economy makes it possible to assess how far the benefits of development reach to people who are not counted by the statistics that are based on official registration or compliance with tax laws. Despite the difficulty of doing so, attempts must be made to identify and measure the informal economy. Each country should aim to develop its system of statistics on the informal economy in order to provide an adequate information base for a wide range of descriptive and analytical purposes, including for (a) describing and enhancing understanding of the informal economy and (b) supporting the development of policies addressing the informal economy, while taking account of specific national needs and circumstances.
- 39.3 The International Labour Organization (ILO) in its Resolution Concerning Statistics on the Informal Economy, (International Labour Office, 2023) adopted by the 21st International Conference of Labour Statisticians (ICLS) established the standards for statistics on the informal economy. Whilst there is commonality between the concepts and definitions in the ILO standards and those in the System of National Accounts (SNA) and the Balance of Payments and International Investment Position Manual (BPM), the meaning of these concepts and definitions is sometimes different from those used in the SNA and BPM. For example, the [BPM/SNA] includes illegal or illicit activities in the production boundary, whereas the ILO standards exclude them from the informal economy. This chapter ~~presents~~summarizes the ILO standards, giving emphasis to the concepts, definitions and classifications used in the ILO standards and explaining their relationship with the [SNA/BPM].
- 39.4 It is a common misconception that GDP is underestimated because it does not include the production of informal businesses and informal labour inputs. Conceptually the SNA includes all productive activities irrespective of whether these activities are formal or informal. The compilation of exhaustive measures in the presence of informality is certainly challenging, but as discussed in SNA paragraphs 7.47 to 7.56, compilers should always endeavor to make efforts to use data sources and estimation methods that cover ~~informal and other~~ non-observed activities. The framework for the informal economy described in this chapter does not focus on developing exhaustive measurements of production, but rather on providing a complete presentation of the informal economy.
- 39.5 The non-observed economy, including non-observed cross border trade in goods and services ~~is a concept that~~, is conceptually distinct and different from the informal economy. The non-observed economy includes activities that, for various reasons, are not captured in regular statistical enquiries. It is a pragmatic term that is used in the context of achieving exhaustive statistics and includes misreporting by formal units such as large

corporations. Efforts to cover the non-observed economy ensure that all productive activities are covered in statistical estimates even if not covered by statistical enquiries. Because informal activities tend to be difficult to measure and are sometimes omitted from statistical surveys or administrative data sources, there tend to be certain overlaps between the informal economy and the non-observed economy. Nevertheless, the concepts serve different purposes, and each includes elements that are not included in the other. The primary focus of this chapter is on the informal economy, but Section F discusses the non-observed economy in its relation to the informal economy.

## 1. The policy interest in measuring informal activities

- 39.6 Interest in the informal economy continues to attract considerable attention. Informal productive activities are often associated with lower and uncertain income for workers since informal workers and enterprises are less protected against negative economic shocks. This may have broader consequences for inequality and poverty since informality is correlated with vulnerability through the denial of rights at work, the absence of sufficient opportunities for quality employment, and the lack of effective social protection. The quantification of the informal economy and data on its characteristics are needed to enhance the international comparability of statistics on the informal economy, the measurement of decent work and the well-being of households and society in general, and in identifying the main drivers of informality. Analysing macro-economic and social policies on the informal economy facilitates the transition from the informal economy to formal productive activities and to the achievement of gender equality, sustainable development and social justice.
- 39.7 It should be noted that the relevance of statistics on the informal economy in a given country will depend on the nature of its society, labour markets and regulations as well as user needs, and that their implementation will therefore, to a certain extent, be determined by national circumstances.

## 2. Structure of the chapter

- 39.8 Sections B and C present a summary of the framework of the 21<sup>st</sup> ICLS *Resolution Concerning Statistics on the Informal Economy*. Section B looks at statistics on economic units and production in the informal economy, clarifies the use of existing terminology, and provides the definitions of the informal economy and the classifications used to identify and analyze informal productive activities. Section C focusses on informal work arrangements. Sections B and C also discuss the relationships between informal economy statistics and the [SNA/BPM7]. Informal aspects of two issues that are of special importance to the [national accounts/balance of payments], i.e., digitalization and informal cross-border flows, are discussed in Section D. Section E summarizes the data sources and the presentation of indicators for the informal economy. The relationship between the non-observed economy and the informal sector is presented in Section F. The interest in the informal economy has led to the production of several handbooks and studies of current practices. ~~It is impossible to report~~ Reporting these in depth ~~is beyond the scope of~~ this chapter, but section G gives a brief description of ~~some of these~~ the main available guidelines and indicates where they may be consulted.

## B. Framework for the informal economy

- 39.9 The standards adopted by the 21<sup>st</sup> ICLS for statistics on the informal economy are designed to guide countries in measuring informal productive activities of workers and economic units. The standards provide a conceptual framework for statistics on the informal economy, definitions of distinct subsets of economic units depending on their status of (in)formality and the intended destination of their production, a set of definitions of distinct subsets of informal work, a set of indicators to provide information on the characteristics, circumstances and needs of workers and economic units, and operational concepts, definitions and guidelines for the compilation of statistics on the informal economy. In designing the framework for statistics on the informal economy, care was taken to maintain coherence with other international statistical standards, particularly regarding the SNA and the BPM. [(x) SNA sentence: The next section explains the relationship between the terminology used in the 21<sup>st</sup> ICLS resolution and the familiar SNA terminology.] [(\*) BPM7 sentence: More detail on the relationship between the terminology used in the 21<sup>st</sup> ICLS resolution and the SNA and BPM terminology is given in 2025 SNA, chapter 39, section B.1, Clarifying the use of familiar terminology.]

## 1. Clarifying the use of familiar terminology (\*)

[Reminder: The ‘(\*)’ denotes SNA-only text that is excluded from BPM7]

- 39.10 The statistics on the informal economy compiled according to the 21<sup>st</sup> ICLS standards are aligned with the SNA, while using different terminologies from the SNA and BPM for some concepts and classifications to allow the statistics to highlight certain features of informality. The different uses of terms are presented below.

### Productive activities of economic units

- 39.11 In both the ICLS standards and SNA, the concept of productive activities of economic units includes processes or activities that are carried out under the control and responsibility of an economic unit, using inputs of labour, capital, goods and services to produce outputs of goods or services. Similarly, for the concept of “economic unit” the definition used in the statistics on the informal economy is aligned with that used in the SNA.

### Productive activities of persons

- 39.12 The concept of productive activities of persons in the statistics on the informal economy ~~is similar to the concept in the SNA as it~~ includes work and labour activities within the SNA production boundary, ~~but it also includes as well as~~ activities outside the SNA production boundary although inside the general production boundary.

### Sector

- 39.13 The term “sector” used in the 21<sup>st</sup> ICLS *Resolution Concerning Statistics on the Informal Economy* does not have the same basis as the usual use of the word sector throughout the SNA. In the SNA, sectors are made up of complete institutional units; in the context of the informal economy only the productive activities are considered and other activities of the unit such as consumption and accumulation are excluded. In addition, the criteria used to identify the sectors in the statistics on the informal economy are based on the intended destination of the production and the formal status of the economic unit. Thus, for example, households having no productive activity are simply not considered in the steps to identify those unincorporated enterprises operated by households that are to be included in the informal economy.

### Enterprise

- 39.14 In the SNA, a corporation represents a single enterprise, but each ~~such~~ enterprise may consist of a number of establishments. A key difference between an enterprise and an establishment is that a full set of accounts must exist, or could be constructed, for an enterprise, but for an establishment a much more restricted set of data is available, typically only information relating to production, number of employees and the capital formation associated with the activity.
- 39.15 Within a household many different types of production activities may take place. ~~For none of these individually nor for the total of all activities that cannot be treated as quasi-corporations does a~~ complete set of accounts ~~does not exist for individual activities that are not activities of quasi-corporations, nor for the total of all household activities.~~ The SNA usage of “unincorporated enterprise” is taken to mean the totality of all unincorporated activity undertaken by a household even though in a supply and use table, for example, this may be partitioned by types of activity and be grouped with establishments of corporations undertaking the same activity.
- 39.16 The use of unincorporated enterprise in the 21<sup>st</sup> ICLS *Resolution Concerning Statistics on the Informal Economy* does not correspond to the sum of unincorporated activity of a household but to each activity separately. In SNA terms, the unincorporated enterprise is broken down into a number of unincorporated

establishments, some of which may be included in the informal economy and some excluded, even for the same household. For example, if one member of a household operates an unincorporated repair business and another member of the same household operates an unincorporated childcare business, they would be treated as separate unincorporated establishments in the informal economy statistics. Furthermore, the informal economy statistics identify individual members of a household as owning and operating each establishment/enterprise and capable of employing workers. In the SNA, it is the household collectively that is responsible for all activity and for employing workers.

## Subsectoring production

- 39.17 The SNA subdivides production into market production, production for own final use and non-market production. Non-market production is not at issue here since it is never undertaken by households. However, to meet the 21<sup>st</sup> ICLS resolution it is necessary to subdivide production by households into production that is mainly for sale or barter and production that is mainly for own final use. In the case of unincorporated enterprises where the production is mainly sold or bartered (intended for the market), all of the production of the unit is included in production by the informal sector, while where the production is mainly for own final use, it is allocated to the household own-use production and community sector.

## Formal sector, informal sector and household own-use production and community sector

- 39.18 The SNA does not use the expression formal sector, but it is not difficult to conceive of all units in the corporations sectors, general government and NPISHs as being part of a formal sector as far as production is concerned. Quasi- corporations are included because they are included in the corporations sectors. However, this is not the same as saying that any unit that is not informal is formal, since households with unincorporated enterprises not included in the informal sector are divided between those that are treated as formal and the rest that are included in the household own-use production and community sector.
- 39.19 The meaning of household units according to the 21<sup>st</sup> ICLS resolution is thus quite different from that of the SNA since the SNA includes as households all the units included ~~under~~ under the 21<sup>st</sup> ICLS resolution as informal and mainly producing for the market, plus households mainly producing for own final use, plus those units with unincorporated enterprises treated as formal, plus households as consumers plus institutional households.

## 2. Informal productive activities

- 39.20 *Informal productive activities* are defined as all productive activities carried out by persons or economic units that are – in law or in practice – not covered by formal arrangements as established by regulations and laws, such as:
- regulations that stipulate the rights and responsibilities and obligations of the economic units and the workers;
  - commercial laws that regulate the productive activities carried out by economic units and their engagement in commercial contracts, including to safeguard their intellectual and physical property;
  - procedures to report economic activities such as fiscal obligations in order, for example, to pay taxes or to cover employees by social security;
  - labour laws and regulations such as those relating to freedom of association, rights to collective bargaining, paid annual leave, paid sick leave, the minimum wage, hours of work, social security coverage and social dialogue; and
  - procedures that regulate access to the institutional infrastructure such as markets, governmental support mechanisms and financial institutions including banks.

- 39.21 Coverage by formal arrangements in law and in practice does not merely imply having legal coverage by the formal arrangements but means that the arrangements should be effectively accessed in practice by the worker and the economic unit by fulfilling procedures that entail duties and obligations for all parties involved.
- 39.22 Informal productive activities can be viewed as an underlying concept that contributes to recognizing two highly linked but also slightly different perspectives of informality, i.e., the perspective of workers and the perspective of economic units. This concept forms the conceptual foundation from which the different statistical components are derived and points toward which statistical components should be statistically quantified and described.
- 39.23 Informal productive activities of persons include informal tasks and duties carried out by persons in informal employment; in formal employment, carrying out partly informal activities tasks and duties; or in unpaid trainee work, volunteer work, own-use production work and other work activities (see section C of this chapter). Informal productive activities of economic units include informal production carried out by economic units in the informal sector or by households producing for own final use, including direct volunteer work, and production by non-formal non-profit organizations. Informal productive activities may be undertaken in most kinds of economic activity, including the agriculture, forestry and fishing industry, and include household own-use production work within the general production boundary. Housing services of owner occupiers are by convention excluded from the informal economy because no informal labour inputs are used for this production activity.

### 3. The informal economy

- 39.24 The *informal economy* comprises all informal productive activities of persons or economic units, whether or not they are carried out for pay or profit. The concept of the informal economy enables the comprehensive measurement of the informal productive activities carried out by economic units and of informal productive activities by workers in relation to employment and undertaken through forms of work other than employment.
- 39.25 For statistical purposes, the concept of the *informal market economy* is defined as all production for pay or profit in the informal sector and all productive activities of workers in employment that are – in law or in practice – not covered by formal arrangements.
- 39.26 Illegal and illicit activities where the production of goods and services are forbidden by law are excluded from the informal economy. However, the production of goods and services, that are usually legal, but become illegal when carried out by unauthorized producers, should be included in the informal economy.
- 39.27 The exclusion of illegal and illicit activities where the goods and services are forbidden by law relates only to the scope of what is measured in the informal economy. In the SNA, illegal productive activities that fit the characteristics of transactions are treated the same way as legal actions and are therefore included within the SNA production boundary (see SNA paragraph 7.53). For example, if the sale of narcotics is forbidden by law, those activities should be excluded from the informal economy statistics, although they are included in the SNA. Similarly, imports and exports of illegal goods and services are included in the external statistics but should be excluded from statistics on informal trade. Transactions in stolen goods are also included in the SNA and BPM but excluded from statistics on the informal economy and from informal trade. However, some activities that are usually legal may be carried out illegally because they are conducted by an unregistered producer (for example, the sale of transport services by an unregistered producer). These activities that are usually legal but may be carried out illegally are not to be regarded as illegal activities and are included in the informal economy statistics as well as the [BPM/SNA].

### 4. ~~Informal~~Formal sector, ~~formal~~informal sector and household own-use production and community sector

- 39.28 The criteria used to identify the sectors in the statistics on the informal economy are based on the intended destination of the production and the status of (in)formality of the economic unit. The intended destination reflects whether, or not, the production is mainly intended for the market with the purpose of generating a profit and income. The criterion of production that is “mainly intended for the market” is similar to the SNA definition of market producers as establishments, “all or most of whose output is market production” (see SNA

- paragraph 7.144). The formal status of the economic unit reflects whether the unit is formally recognized by government authorities as a distinct producer and is thus covered by formal arrangements.
- 39.29 The framework for informal economy statistics assigns all economic units to one of three sectors: the formal sector, the informal sector or the household own-use production and community sector, depending on the intended destination of the production and the status of (in)formality of the economic unit.
- 39.30 The **formal sector** comprises economic units that are formally recognized as distinct producers of goods and services for the consumption of others and whose production is mainly intended for the market with the purpose of generating an income or profit or for a non-profit purpose (i.e. non-profit institutions), or non-market production for use by other economic units, including the society as a whole. With respect to the SNA sectors, financial and non-financial corporations and general government are always formally recognized and therefore are part of the formal sector. In addition, formally recognized NPISHs are part of the formal sector. Households are assigned to the formal sector if they undertake production through a household unincorporated market enterprise that is registered in a government established system of registration or employs one or more persons to work as an employee with a formal job. Household unincorporated market enterprises that keep a complete set of accounts for tax purposes are treated as quasi-corporations and included in either the financial or non-financial corporations sectors in the SNA and as part of the formal sector in the ILO statistics.
- 39.31 The **informal sector** comprises economic units whose production is mainly intended for the market with the purpose of generating income and profit but that are not formally recognized as producers of goods and services distinct from the own-use production of the owner-operators' household. These economic units are all classified in the SNA as part of the household sector and may include informal partnerships. These economic units undertake production mainly intended for the market through a household unincorporated market enterprise that does not keep a set of accounts for tax purposes, is not registered in a governmentally established system of registration and does not employ one or more persons to work as an employee with a formal job.
- 39.32 The **household own-use production and community sector** comprises ~~economic units that are not formally recognized as producers of goods and services for the consumption of others; either:~~ households whose production (excluding housing services of owner occupiers) is ~~either:~~ mainly for the household's own final use or for the use of other households, without the purpose of generating income and profit for the producing household or households; or non-market production by the members of a non-formal non-profit ~~organization~~ organizations (i.e. an informal and temporary NPISH), ~~which~~ serving households. These units are characterized by not being formally recognized as distinct producers of goods or services and undertaking production that is mainly intended for the own final use by households of households or for the use of other households without the purpose of generating an income or profit. The production boundary for the household own-use production and community sector extends the SNA production boundary in that the sector includes (and the SNA production boundary excludes) most services produced for own use by households (see SNA paragraphs 7.28–7.32).
- 39.33 Table 39.1 illustrates the classification of economic units in the formal sector, the informal sector and the household own-use production and community sector, adding detail on the different forms of informal paid and unpaid work that may be used as input to their formal or informal production.

**Table 39.1: Informal productive activities in the informal economy**

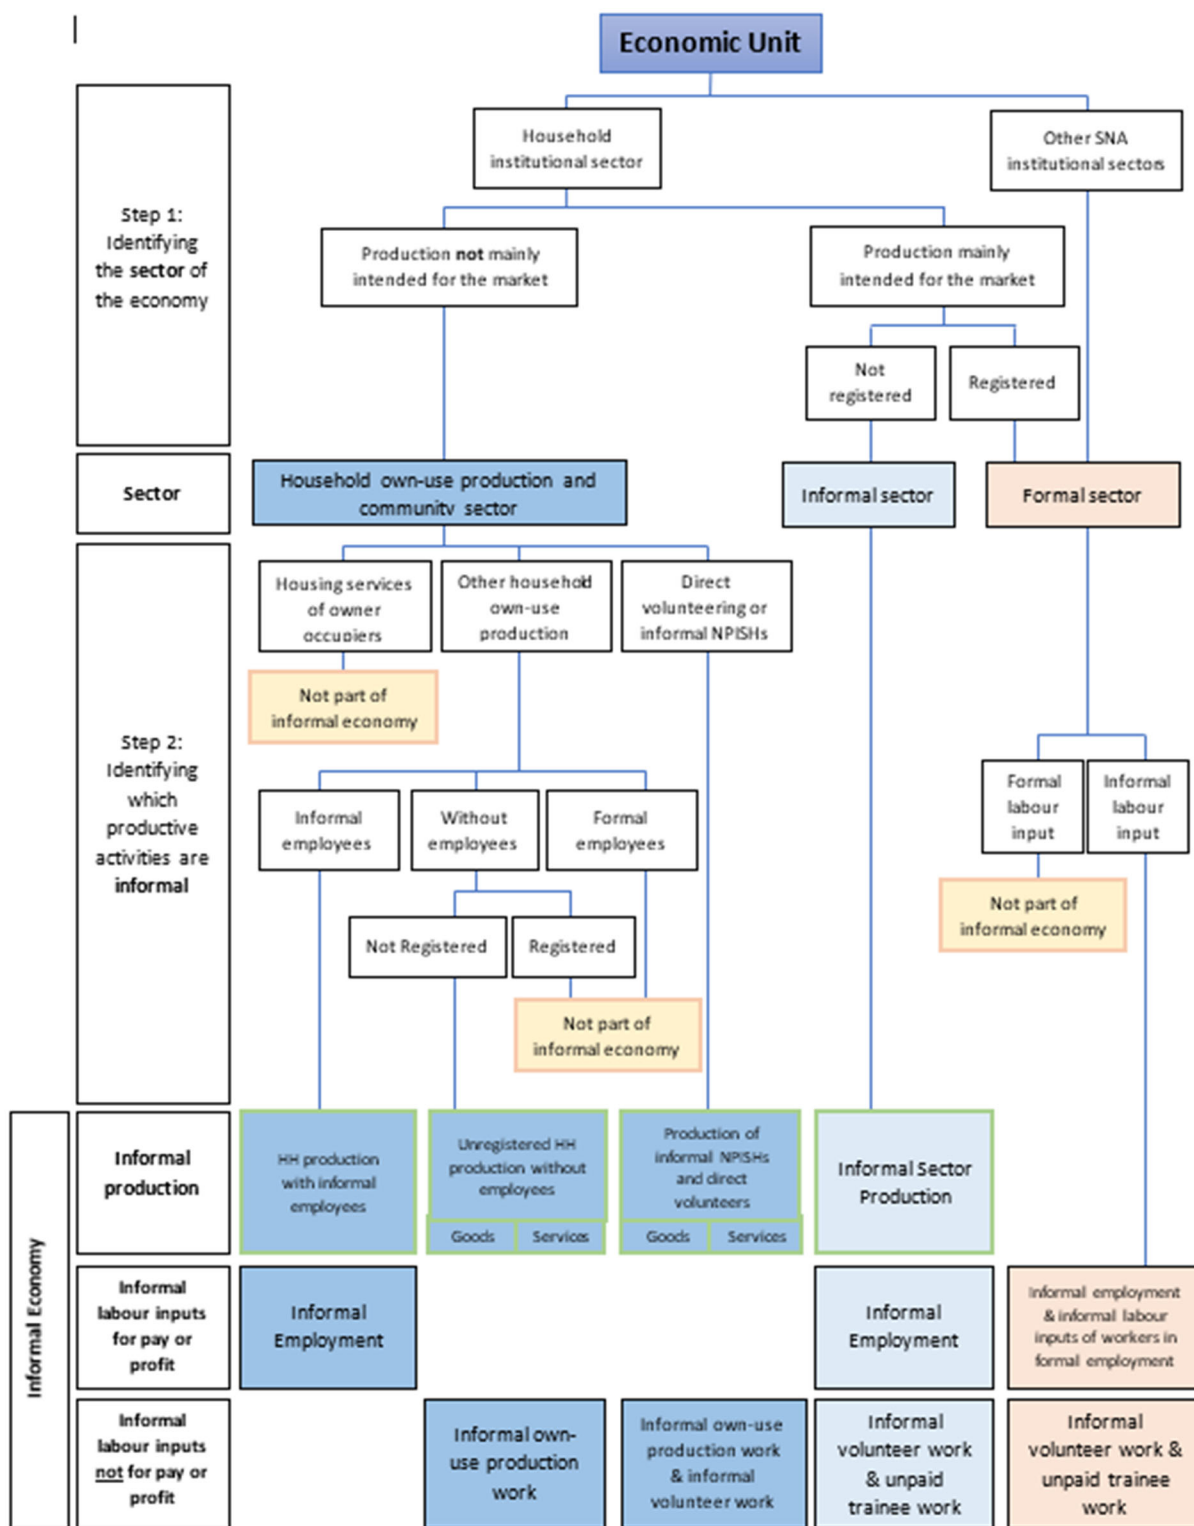

Sector		Formal sector	Informal sector*	Household own-use production and community sector			
Informal productive activities		Production in the formal sector is never informal  All informal labour inputs of workers engaged by: formal household unincorporated market enterprises, formal NPISHs, corporations, and general government	All production by informal household unincorporated market enterprises  All labour inputs used to undertake this production	Production by household engaging informal employees  All labour inputs used to undertake this production	Informal household own-use production including non-formal non-profit organizations and direct volunteers  All labour inputs used to undertake this production		
Type of informal labour inputs	For pay or profit	Informal employment*	Informal employment*	Informal employment*			
		Partly informal labour inputs of persons in formal employment*		Partly informal labour inputs of persons in formal employment*			
	Not for pay or profit	Informal unpaid trainee work	Informal unpaid trainee work		Informal volunteer work		
		Informal volunteer work	Informal volunteer work		Own-use production work		
Relation to SNA production boundary:		Goods and Services				Goods	Services
		SNA production boundary**					
		General production boundary					

\* Components of the informal market economy

\*\* The SNA production boundaries also includes illegal activities that are out of scope in the informal economy framework.

39.34 The 21<sup>st</sup> ICLS *Resolution Concerning Statistics on the Informal Economy* includes a set of operational definitions used to clearly identify the economic units belonging to each of the three sectors. Figure 39.1 illustrates how the framework identifies informal productive activities of economic units. The links between the three sectors (i.e., the formal sector, the informal sector, and the household own-use production and community sector) and the institutional sectors of the SNA are shown in Table 39.2.

Figure 39.1: Decision tree to identify informal productive activities of economic units

Note: The measure of production used in this decision tree is based on the general production boundary.

**Table 39.2: The formal sector, informal sector and household own use production and community sector and its relation to the SNA institutional sectors**

	SNA institutional sectors								
	a) Non-financial corporations and b) Financial corporations		c) General government	d) NPISHs	e) Households				
Type of SNA institutional unit	Corporations	Quasi-corporations	Government units	NPISH	Households (excluding institutional HH and HH as consumers)				
					Unincorporated household market enterprises				
Main type of production	Market production	Market production	Non-market production	Non-market production	Market production	Market production	Own-use production		
							Housing services of owner-occupiers	Production by households for own use with employees	Production by households for own use without employees. Including non-formal non-profit organizations and direct volunteers.
Operational definition as part of identifying the formal status	Incorporated enterprise	Have a complete set of <del>account for tax</del> <u>purposes</u> <u>account s</u> ; registered for tax or similar <u>purposes</u>	Always formally recognized	Registration	Registered or engages formal employees.	Not registered and does not engage formal employees.	Never informal	Production is informal if employees are informal employees	Direct volunteers and non-formal non-profit organizations are always informal; other HH production for own use without employees is informal unless production is registered.
Within SNA production boundary	Yes							Goods <u>Yes</u>	Services <b>No</b>
Sector of the economy	Formal					Informal Sector	Household own-use production and community sector		
Productive activities are part of informal economy	Only informal labour inputs					Yes, both production and labour inputs	No	Yes, both production and labour inputs if employees are informal.	Yes, both production and labour inputs unless production is registered

## C. Informal work

- 39.35 This section defines and classifies informal work in the 21<sup>st</sup> ICLS resolution, points to the alignment of these concepts with international standards such as the International Classification of Status in Employment, presents the informal productive activities of persons in relation to the sectors in the 21<sup>st</sup> ICLS resolution, and defines and presents informal and formal employment in relation to those same sectors.
- 39.36 The 21<sup>st</sup> ICLS *Resolution Concerning Statistics on the Informal Economy* related to measuring informal productive activities of persons provides a set of definitions for distinct subsets of informal work. In the informal economy, the concept of “productive activities of persons” is aligned with the definition of “work” in the international standards of work, employment, and labour underutilization. It includes activities within the SNA production boundary as well as activities outside the SNA production boundary but inside the general production boundary. Work can be subdivided into five distinct forms:
- a. own-use production work;
  - b. employment work;
  - c. unpaid trainee work;
  - d. volunteer work;
  - e. other work activities.
- 39.37 Informal work consists of productive activities performed by persons, as defined by the latest standards on work and employment, that are – in law or in practice – not covered by formal arrangements such as, regulations and provisions that promote or facilitate the work and protect and regulate the actions and functions of the worker. It comprises:
- a. productive activities carried out by persons in employment that are, in law or in practice, not covered by formal arrangements such as regulations and laws that stipulate the rights and responsibilities, obligations and protection of the economic units and the workers; and
  - b. productive activities carried out in relation to:
    - i. own-use production work;
    - ii. volunteer work;
    - iii. unpaid trainee work; and
    - iv. other work activities.
- 39.38 Persons carrying out informal productive activities in the informal economy may carry out this work for economic units categorized in the formal sector, informal sector or household own-use production and community sector (see table 39.3).

**Table 39.3: Informal productive activities by persons in the informal economy**

Persons		Informal work		
Main intention of the productive activities		For pay or profit		Not mainly intended to generate pay or profit
		Informal productive activities in relation to employment		Informal productive activities in relation to forms of work other than employment
Informal productive activities by persons		Formal employment with partly informal activities *	Informal employment *	Informal unpaid trainee work Informal organization-based volunteer work Informal other work activities

			Informal sector *	Informal sector *
		Household own-use production and community sector	Household own-use production and community sector	Household own-use production and community sector

\* Components of the informal market economy.

## 1. Informal and formal employment

39.39 Statistics on informal employment aim at:

- establishing whether the productive activities defined as employment are, in law and in practice, covered by formal arrangements and the formal status of the economic unit for which this work is carried out; and
- describing the structure and extent of informal employment, identifying groups of persons in employment most represented and at risk of informality, and providing information on exposure to economic and personal risks, decent work deficits and working conditions.

39.40 **Informal employment** is defined as any activity of persons to produce goods or provide services for pay or profit that is - in law or in practice - not covered by formal arrangements such as commercial laws, procedures to report economic activities, income taxation, labour legislation and social security laws and regulations providing protection against economic and personal risks associated with carrying out the activities. Informal employment comprises activities carried out in relation to informal jobs held by:

- independent workers who operate and own or co-own an informal household unincorporated market enterprise;
- dependent contractors who do not have a formal status in relation to the legal administrative framework or whose activities are not effectively covered by formal arrangements;
- employees, if their employment relationship is not, in practice, formally recognized by the employer in relation to the legal administrative framework of the country or not associated with effective access to formal arrangements; and
- contributing family workers whose work relationships are not formally recognized in relation to the legal administrative framework of the country or not associated with effective access to formal arrangements.

39.41 All tasks and duties carried out in relation to an informal job are considered to be informal productive activities. Informal productive activities performed by persons may also be carried out in relation to formal jobs if a subset of the tasks and duties carried out are not effectively covered by formal arrangements.

39.42 (\*) Persons may have one or several formal or informal jobs, or both, during a given reference period.

Dependent workers have an informal or formal job for each economic unit on which the worker is dependent. Independent workers have an informal or formal job for each informal or formal economic unit they operate and own or co-own. (Independent and dependent workers are discussed in SNA paragraph 16.41.) Employed persons with an informal main job comprise all employed persons with an informal main job where the main job is the job with the longest hours usually worked as defined in the latest international statistical standards on working time. In the absence of information regarding hours usually worked, other information such as income from each job could be used to identify the main job. Employed persons with an informal secondary job comprise all employed persons with an informal second job or additional jobs.

- 39.43 (\*) The International Classification of Status in Employment (ICSE-18) classifies jobs held by persons according to type of authority. There are two broad categories: independent workers and dependent workers, where the former includes owner-operators of corporations and independent workers in household unincorporated market enterprises, and the latter includes dependent contractors, employees and contributing family workers.
- a. Independent workers own the economic unit for which they work and control its activities.
  - b. Dependent workers are workers who do not have complete authority or control over the economic unit for which they work.
- 39.44 (\*) Persons holding informal jobs may be categorized in the informal sector, formal sector or household own-use production and community sector, depending on the sector of the economic unit for which the work is carried out or, in the case of dependent contractors, on their formal status in relation to the legal administrative framework of the country.
- 39.45 (\*) **Formal employment** is defined as any activity of persons to produce goods or provide services for pay or profit in relation to a formal job, where the activities are effectively covered by formal arrangements. Formal employment comprises productive activities carried out in relation to formal jobs held by:
- a. independent workers in employment who operate and own or co-own a formal economic unit;
  - b. dependent contractors who have a formal status in relation to the legal administrative framework of the economy and whose activities are associated with effective access to formal arrangements;
  - c. employees, if their employment relationship is, in practice, formally recognized by the employer in relation to the legal administrative framework of the economy and associated with effective access to formal arrangements; and
  - d. contributing family workers carrying out work for a formal economic unit and whose work relationships are formally recognized in relation to the legal administrative framework of the economy and associated with effective access to formal arrangements. Registration of the job held by the contributing family worker and contribution to a job-related statutory social insurance scheme implies that the worker is employed formally in that job.
- 39.46 (\*) Persons holding formal jobs may be categorized in the formal sector or household own-use production and community sector depending on the sector of the economic unit for which the work is carried out or, in the case of dependent contractors, on their formal status in relation to the legal administrative framework of the economy.
- 39.47 (\*) Table 39.4 shows informal and formal jobs for five types of status in employment—owner-operators of corporations, independent workers in household unincorporated market enterprises, dependent contractors, employees, and contributing family workers. The cells numbered 1 through 8 represent various types of informal jobs. The cells shaded in light blue refer to formal jobs, and cells shaded dark blue are jobs which, by definition, do not exist in the economic units in that sector. The 21<sup>st</sup> ICLS *Resolution Concerning Statistics on the Informal Economy* elaborates the definitions used to clearly identify the five types of status in employment.

**Table 39.4: Informal and formal jobs by status in employment and sector (\*)**

Sector of the economic unit for which the work is carried out	Independent workers <sup>1</sup>			Dependent workers					
	Owner-operators of corporations <sup>2</sup>	Independent workers in household (unincorporated) market enterprises <sup>3</sup>		Dependent contractors <sup>4</sup>		Employees		Contributing family workers	
	Formal	Informal	Formal	Informal	Formal	Informal	Formal	Informal	Formal <sup>5</sup>
Formal sector				1		2		3	
Informal sector		4		5		6		7	
Household own-use production and community sector						8			

Note: Cells shaded in dark blue refer to jobs, which, by definition, do not exist in economic units located in the specific sector. Cells shaded in light blue refer to formal jobs. Informal employment consists of the informal jobs in cells 1–8.

<sup>1</sup> Including employers and independent workers without employees (before ICSE-18 labelled Own-account workers).

<sup>2</sup> Including the ICSE-18-A categories 11 and 21.

<sup>3</sup> Including the ICSE-18-A categories 12 and 22.

<sup>4</sup> The sector of dependent contractors does not reflect the sector of the economic unit on which they depend but their formal status in relation to the legal administrative framework of the country.

<sup>5</sup> The existence of formal jobs among contributing family workers carrying out work for an economic unit in the formal sector depends on the national context (see paragraph 39.45d).

39.48 Depending on the national context and need, countries may identify persons with formal jobs carrying out partly informal productive activities and report the number of such persons, the hours spent on informal activities, or the earnings received from paid informal activities in relation to formal jobs.

## 2. (\*) Informal work other than employment

39.49 Informal work other than employment comprises informal productive activities in relation to own-use production work, volunteer work, unpaid trainee work and other work activities where the unpaid work is not covered by formal arrangements such as regulations and provisions that promote or facilitate the work and protect and regulate the actions and functions of the worker. Measuring the informal or formal nature of work other than employment supports the recognition and valuation of all forms of work, essential for achieving development goals such as attaining gender equality, social inclusion and social protection and reducing poverty. Informal work other than employment is not included in Table 39.4. Detailed definitions of informal work other than employment are provided in the 21<sup>st</sup> ICLS *Resolution Concerning Statistics on the Informal Economy*.

## D. Digitalization and informal cross-border flows

39.50 The conceptual framework, definitions and classifications that underlie the statistics on the informal economy and their relation to the System of National Accounts were presented in sections B and C. In practice, compilers will be confronted with many practical issues in collecting data and deriving estimates for informal activities. This section focuses on two issues that are of particular interest to national accounts and balance of payments statistics – digitalization and informal cross-border flows.

### 1. Digitalization

- 39.51 Digitalization penetrates many aspects of economic activity which leads to concerns about the possible mismeasurement of economic activity. New types of economic activities often make use of digital technologies and create new types of jobs, including jobs that are considered informal. Many of these jobs facilitated by digitalization are **as in the role of** dependent contractors as described in Section C of this chapter.
- 39.52 Most of the new forms of dependent contractors facilitated by digitalization are dependent on large formal enterprises that provide a digital intermediation service. Examples include households that provide transport or accommodation services. The formal or informal status of dependent contractors would vary based on the legal administrative framework of an economy, which regulates the ties between dependent contractors and formal economic units. For example, if dependent contractors are registered, participate in social insurance schemes or are regulated by the government in ways that facilitate their work or protect them as workers, they are classified as formal workers. If the government does not require the formal economic units to register or provide formal regulations or protections to the dependent contractors with whom they work, then the dependent contractors will be informal workers.
- 39.53 Digitalization facilitates household participation in production activities that can be informal, such as through digital marketplaces. Digitalization also provides opportunities for households to deliver interactive services such as online learning and entertainment channels where income is earned by the household through advertising or from viewer subscriptions. Households that receive monetary remuneration for uploaded content can be considered unincorporated household enterprises. If the household is not recognized by government authorities as a distinct market producer and thus is not covered by formal arrangements, then it is regarded as an informal enterprise. For multinational enterprise groups that operate digital platforms in a number of countries, the formal/informal status of the dependent contractors may vary from country to country depending on the legal arrangements in each country.
- 39.54 Additional general information on the role of digitalization and how it should be accounted for is provided in chapter [22 (SNA)/16 (BPM7)].

## **2. Informal cross-border flows [This will be a headline section in BPM7]**

- 39.55 Informal cross-border flows pose challenges to data collection and estimation because they represent transactions undertaken by small units and households that may not be covered by the regular data collection programmes used for external sector statistics.
- 39.56 The framework for the informal economy presented in this chapter relates to the production of goods and services in the domestic economy. It is possible to extend the framework to account for external transactions related to activities of informal workers and informal economic units. These transactions would be recorded primarily in the current account and include the following:
- a. Trade in goods conducted by informal workers and informal economic units;
  - b. Trade in services by informal economic units (exports and imports);
  - c. Informal employment of non-resident workers;
  - d. Remittances related to the informal economy.
- 39.57 Trade in goods conducted informally includes small scale but frequent movement of goods between neighboring countries by informal units or workers, shuttle trade (see BPM x.xx), fish catch traded between vessels at sea where the vessel of the compiling economy is operated by informal units, and smuggling of otherwise legal goods by informal units or workers.
- 39.58 If an informal worker carries goods over the border for a formal enterprise, then the change of ownership is between a formal unit and a non-resident. In this case, only the work done by the carrier of the goods would be part of the informal economy (either a service by an unincorporated market enterprise or work by an informal employee). The payment from the formal unit to the carrier of the goods could be either an international or a domestic transaction depending on the residency of the parties.
- 39.59 The carriage of goods by informal workers and informal economic units across country frontiers is an important component of the informal economy, particularly in developing countries. Compilers of trade in

goods are encouraged to collect data on the value of goods traded by informal units and workers and to gather information on the persons conducting informal trade when these activities are significant. One approach that has been used is to conduct routine surveys at border stations where imports and exports of goods that are carried over the border by informal units or informal workers can be recorded or observed.

**39.60** Trade in services by informal units includes services such as ~~room~~:

- a. **Room** rental, ride services or informal restaurant and bar services that are provided by informal units to travelers who are temporarily present in the reporting economy; ~~exports~~
- b. **Exports** and imports of services such as hairdressing, housekeeping and caring for persons, or construction provided by self-employed persons that move across borders but are not registered in a governmentally established system of registration in either their economy of residence or the economy of activity (see paragraph[(BPM) 4.116-4.119] for a discussion of residency); and ~~cross~~
- a.c. **Cross**-border services that are delivered online such as tutoring, wellbeing and other income generating online services where the service-provider is working informally and has not registered in a governmentally established system of registration.

~~39.60~~**39.61** Undeclared and underdeclared trade in goods or services by formal units is not part of the informal economy but may be accounted for as non-observed international trade – see section F of this chapter.

~~39.61~~**39.62** Some trade that is part of the informal economy in one economy may not be considered informal in the counterpart economy. This would occur, for instance, if a fishing vessel operated by an informal unit traded with a fishing vessel operated by a formal unit from another economy. Another example would be for accommodation services provided by informal units to non-residents; this would be considered part of the informal economy in the economy of the service provider, but for the economy of the traveler this would not generally be recorded in the statistics on the informal economy.

~~39.62~~**39.63** Some nonresidents such as seasonal workers and nonresident students may engage in informal employment because they do not have the appropriate employment permits to engage in formal employment. Volunteer work by nonresidents may also be considered informal depending on whether the work satisfies the criteria discussed in paragraph **39.49** and the 21<sup>st</sup> ICLS *Resolution Concerning Statistics on the Informal Economy*.

~~39.63~~**39.64** The 21<sup>st</sup> ICLS resolution does not discuss remittances. However, as migrant workers and non-national residents are often at risk of informality, it may be informative to provide information on remuneration of employees and personal transfers that relate to informal workers and informal economic units.

~~39.64~~**39.65** Remittance outflows related to the informal economy include personal transfers of income earned from informal employment by residents and personal transfers from income earned by resident persons belonging to an informal economic unit, as well as remuneration of employees less transport and travel of border, seasonal and other short-term nonresident workers such as unregistered nonresident domestic workers employed by households. The counterpart country would record these data as remittance inflows, but the information may not inform the same policy needs as other data on the informal economy.

~~39.65~~**39.66** As explained in paragraphs **39.26–39.27**, trade in goods and services that are forbidden by law are excluded from the statistics on the informal economy. However, the balance of payments statistics include all trade in illegal goods and services, so care should be taken in reconciling the balance of payment statistics with external transactions from statistics on the informal economy to account for the difference in treatment.

## **E. Data sources and presentation of indicators**

~~39.66~~**39.67** The standards for statistics on the informal economy described in sections B and C provide the conceptual basis for statistics to be compiled in a harmonious and comparable manner from different data sources. The sources and data collection methods will depend on statistical capacity, national priorities, measurement objectives and the relevant reference unit.

## 1. Criteria for selecting data sources (\*)

[39.67](#)[39.68](#) (\*) Complete coverage of the desired elements might require the use of multiple sources. A close collaboration between different national institutions, including the main users of the data, national statistical offices and other national data producers is important to ensure harmonization across sources and institutions.

[39.68](#)[39.69](#) (\*) Different data sources each have their own strengths and limitations and can be viewed as complementary to provide data on different aspects of the informal economy. The ILO provides methodological guidance that can facilitate international comparability for data on the informal economy.

[39.69](#)[39.70](#) (\*) For any data source the quality of the data generated will be determined by the combination of methodologies used and concepts applied. Differences in survey sample sizes, population coverage, unit of observation, ability to apply definitions comprehensively and range of data generated, among others, will have implications in respect of precision, bias and comparability across sources. When planning the system of statistics on informality, close attention should be paid to the methodologies used to ensure that estimates generated are as representative as possible of the target population, that the coverage of indicators produced is in line with objectives, and that samples are adequate to achieve desired levels of precision.

[39.70](#)[39.71](#) (\*) To enable clear and appropriate interpretation of the statistics it is crucial that data quality is assessed and reported on transparently. Metadata describing the source, the concepts, the methodologies, and the results generated should be published alongside any published data.

## 2. Data collection (\*) note that Section E will not have any subsections in BPM7

[39.71](#)[39.72](#) (\*) In general, household-based surveys, particularly labour force surveys, are important data sources for producing statistics with persons and jobs as reference units. Labour force surveys, generally characterized by detailed sequences of questions on the characteristics of jobs, are typically the recommended source of statistics for monitoring the extent of informal and formal jobs, assessing levels of informality and formality and levels of protection and vulnerability, identifying persons most exposed to and most represented among informal jobs, and assessing the working conditions of persons in formal and informal jobs. They are also a useful source to identify drivers of informality associated with the structure of the labour market. A combined household-establishment survey may be able to meet the same objectives.

[39.72](#)[39.73](#) (\*) Other household surveys, such as surveys on poverty and living standards, or household income and expenditure surveys, generally include less detailed sequences of questions on labour and may be designed with smaller sample sizes than a typical labour force survey. When such surveys include questions to identify persons having informal and formal jobs, they can be particularly suited to the production of data to analyse the relationship between informality and the main topics covered by the survey such as poverty, the level and composition of income and expenditure, and access to social protection beyond job-related contributory social security.

[39.73](#)[39.74](#) (\*) Other specialized household surveys, such as time-use surveys and household-based surveys on agriculture, education and training, or specialized surveys on digital platform employment and labour migration, may be better suited for the measurement of specific working activities, or for focusing on specific subgroups of the population. Time-use surveys can be an important source for the production of statistics on participation and time spent in informal unpaid work such as the own-use provision of services (in particular informal unpaid domestic work and care work). Surveys targeting specific subgroups of the population might be more appropriate for groups whose total number might be small in labour force survey samples, limiting the possibility to produce reliable statistics. It should be taken into account that the constraints of sample surveys often mean that certain groups at greater risk of informality, such as persons with a disability, migrant workers or digital platform workers, are also those likely to be under-represented in the sample.

[39.74](#)[39.75](#) (\*) National population censuses are an important source of statistics on employment and often provide the basis for designing survey samples, integrating national data sources, and producing small area estimates. Including questions to classify those employed according to the formal or informal nature of their job can allow the generation of estimates of informality for small geographical areas as well as for small population groups.

[39.75](#)[39.76](#) (\*) Economic censuses, enterprise-based surveys and mixed surveys are the main data sources for

the analysis of informal sector and formal sector economic units, their production and contribution to GDP, and their characteristics. In general, due attention should be paid to ensuring that the scope of activities and type of economic units covered (in terms of size, place of work, economic activity and institutional sector) do not imply an exclusion of economic units likely to be informal (for example, independent workers without employees, units under a certain size threshold, units carrying out agricultural activities, units with non-fixed premises or home-based activities). To achieve comprehensive coverage of informal sector units, special attention should be paid to the sampling methods and frame used. The use of area-based sampling frames can be a useful method to establish an exhaustive list of units covering household-based activities and activities taking place in non-fixed locations.

[39.76](#)[39.77](#) (\*) Mixed surveys, that is, combined multi-stage household and establishment surveys, are specifically designed to identify and target economic units in the informal sector. Deriving their sample from a representative household survey, such as the labour force survey, ensures the inclusion of all types of activities within the informal sector, home-based activities, activities carried out from fixed locations as well as non-fixed locations. This requires an identification of economic units in the informal sector, through their owner(s), in the first phase. Care should be taken to ensure a sufficient sized representative sample of economic units in the informal sector.

[39.77](#)[39.78](#) (\*) Administrative records can be used as part of an indirect estimation of informal employment and of the informal sector because they provide information on formal employment and the formal sector. The number of persons covered by formal arrangements can, for example, be estimated in taxation systems, employment services and social security schemes. The size of the formal sector could be estimated by the use of business registers, tax registers and the like. The possibilities to do so depend on the structure and content of the country-specific administrative sources. Priority should, however, in general be given to direct methods based on household surveys and enterprise-based surveys or mixed surveys for more accurate estimations of the total informal employment and the informal sector. Administrative information such as legal identity of the economic unit, taxation, declared earnings or income and contributions to social insurance in relation to a specific job can also be used as relevant auxiliary information in surveys to further support the identification of formal jobs and formal economic units. This requires that a direct linkage at the level of persons and jobs or economic units is feasible in the country.

[The following paragraphs will replace the above in *BPM7*. The '(x)' denotes *BPM7*-only paragraphs that will not be in *SNA*.]

[39.78](#)[39.79](#) (x) Compilers can use a range of statistical approaches including a combination of direct and indirect sources to estimate the size of the activities of the informal economy. These methods would be determined by the features of the informal economy in the compiling country as well as availability of source data and statistical capacity. The exchange of experiences and knowledge between national accounts and balance of payments compilers, and, also, between regulatory and policy agencies and statistics-producing agencies can be used to develop, for example, statistical models to estimate informal activities. National compilers are also encouraged to use innovative data sources, such as those provided by financial intelligence units and law enforcement agencies to develop estimates. In general, coverage of the informal economy, in both the national accounts and external sector statistics, requires additional source data, including through surveys.

[39.79](#)[39.80](#) (x) Details of sources and survey methods for collecting data on the informal activities in the economy are presented in 2025 *SNA* chapter 39 – Informal economy which is a joint or companion chapter to this current chapter. The methods described in the *SNA* chapter can be applied to gather data on the informal economic units and persons who trade informally, particularly for trade in services.

[39.80](#)[39.81](#) (x) If trade in goods and services is compiled separately from the national accounts, or if more than one agency is involved, compilers can cooperate to provide coherent statistics on the informal economy and to avoid duplication of work.

[39.81](#)[39.82](#) (x) Compilers may wish to identify trade that is estimated using these approaches as an “of which” sub-item of ~~general merchandise~~ trade in goods and trade in services. Compilers may also choose to present data in a standalone publication with information, for example, on the extent of informal trade, the products

being traded, the gender and nationalities of the persons involved in trading, and the modes of transport being used.

### 3. (\*) Presenting indicators on the informal economy [This section is excluded from BPM7]

[39.8239.83](#) To support the development of national policies and interventions for addressing the consequences of informality and facilitating transitions to formality based on evidence, a set of indicators should be selected reflecting the national context, priorities and objectives. The indicators to be produced will depend on the specific component of the informal economy under scrutiny, data sources and national policy goals. The information relating to activities undertaken informally extends, in terms of the SNA, only as far as the production account and the generation of earned income account.

[39.8339.84](#) The indicators linked to the different components of the informal economy could be structured to provide information on six dimensions of informality:

- a. the extent of informality – the prevalence of informality across jobs, economic units and activities;
- b. the composition of informality – the distribution of informal and formal jobs and economic units by socio-demographic, employment-related characteristics and characteristics of the economic units and socio-demographic characteristics of the owner or owners;
- c. the exposure to informality – the percentage of persons with informal main jobs and of economic units in the informal sector by socio-demographic, employment-related characteristics and characteristics of the economic units and socio-demographic characteristics of the owner or owners;
- d. working conditions and levels of protection for those in informal and formal employment, productivity and factors constraining or enhancing the development and sustainability of informal economic units and formal ones;
- e. contextual vulnerabilities – including poverty, inequalities, discrimination and other conditions such as limited or no access to land and natural resources; and with regard to all income sources and social protection from all household members, as well as the composition of households; and
- f. other structural factors.

The 21<sup>st</sup> ICLS *Resolution Concerning Statistics on the Informal Economy* elaborates on the various possible indicators covering these six elements. A wider set of indicators to further support the national production of informality statistics can also be found in the ILO Informal Economy Indicator Framework available at: [insert link to Framework].

## F. The non-observed economy [adjusted in BPM7 to discuss non-observed trade]

[39.8439.85](#) The part of the economic activity difficult to measure has become known as the Non-Observed Economy (NOE) and several publications have been dedicated to measuring it, notably the handbook *Measuring the Non-Observed Economy* (Organisation for Economic Co-operation and Development, International Monetary Fund, International Labour Organization and CIS STAT (2002)). As the techniques in the handbook make clear, a specific measure of the non-observed economy is not important in itself. Attention focuses on ensuring that the measurement of total production is complete or “exhaustive”. The term non-observed economy is used in the context of achieving exhaustiveness of national accounts statistics, focusing on GDP in the context of production. In the same way, non-observed trade is used to describe cross border trade that is difficult to measure in the context of exhaustiveness.

[39.8539.86](#) There is a large overlap between the non-observed [economy/trade] and the informal [sector/trade]. (We focus here on the informal sector rather than the informal economy because the activities of the informal sector are entirely within the SNA production boundary and can thus be compared to the non-observed economy.) However, while the non-observed [economy/trade] and the informal [sector/trade] overlap, neither is a complete subset of the other. This can be seen in figure [39.2](#). The solid circle represents the non-observed

[economy/trade] and the dotted circle the informal [sector/trade]. Thus, the overlap consists of [activities/trade] that are not observed and undertaken informally but there are some [activities/trade] that are not observed but are not undertaken informally and some that are undertaken informally but are observed. The relative size of the three segments in figure 39.2 will vary from country to country.

**Figure 39.2: The non-observed economy and the informal sector [with similar diagram replacing trade for economy in BPM7]**

39.8639.87 Efforts to cover the non-observed [economy/trade] ensure that all enterprises are covered in statistical estimates even if not covered by statistical enquiries. Some of the supplementary estimates may well relate to those activities of household unincorporated enterprises considered to be informal, but some will relate to large enterprises, not regarded as informal. In addition, the non-observed [economy/trade] aims to cover misreporting in large enterprises, whether this is inadvertent or deliberate.

39.8739.88 Within the informal sector, some information may be captured statistically. Consider a household that lets rooms to visitors for one or several nights. The activity cannot be treated as a quasi-corporation because it is impossible to make a clear separation of costs from regular household costs and to partition that fraction of the house treated as an asset associated with the letting of rooms from its main function as a family home. However, the value of the letting activity may be captured in a survey directed at tourism activities, for example.

39.8839.89 Other examples might be considered. [Street traders/Individual cross-border traders] or taxi drivers may be both not observed and informal. A small food producer may be formal but [too small to be covered by statistical enquiries/may trade at below threshold values] and therefore not observed. Teaching assistants may be informal but observed. The situation is complicated by the fact that street traders, taxi drivers, small food producers and teaching assistants may be formal in some countries and informal in others, just as they may be observed in some and not in others.

39.8939.90 It should be noted that all economies have both non-observed parts of their economies and informal enterprises, though the scale of each and the policy interest in identifying them may vary. More detailed information about the scope and measurement of the non-observed economy is available in publications such as the one mentioned in paragraph 39.84.

## G. Guidelines and handbooks on the informal economy and the non-observed economy

~~39.90~~39.91 Significant advances in methodology have taken place in fields related to the informal economy. Also, countries have gained extensive experience in collecting and working with data on the informal sector. These developments are highlighted in various guidelines and handbooks on statistics on the informal economy as well as handbooks on the measurement of the non-observed economy in the SNA.

- As discussed in this chapter, the *Resolution Concerning Statistics on the Informal Economy* adopted at the 21<sup>st</sup> International Conference of Labour Statisticians, (International Labour Office, 2023) provides the standards for statistics on informality.
- The International Labour Organization also prepared a manual in 2013 for preparing estimates of the informal sector and informal employment, *Measuring Informality: A Statistical Manual on the Informal Sector and Informal Employment* (International Labour Office, 2013). Although this manual pre-dates the latest standard presented in the 2023 ILO *Resolution*, it nevertheless provides useful guidance on practical aspects of collecting and compiling informality statistics.
- A wider set of indicators to further support the national production of informality statistics can also be found in the ILO Statistics on the Informal Economy page available at: <https://ilostat.ilo.org/topics/informality/>.
- Chapter 6 of the Eurostat manual, *Essential SNA: Building the Basics* (European Union, 2014) provides a practical overview of how to address exhaustiveness, the non-observed economy, and statistics on informality. Eurostat has also developed a “Tabular Approach to Exhaustiveness” which is used to help ensure comparability.
- Research on statistical methods for improving the exhaustiveness of measures of economic production led to the preparation of the handbook, *Measuring the Non-Observed Economy - a Handbook* by the Organisation for Economic Co-operation and Development, International Monetary Fund, International Labour Organization and CIS STAT (2002).
- The UNECE published *Non-Observed Economy in National Accounts: Survey of Country Practices* (United Nations Economic Commission for Europe, 2008) which summarizes practices as of that date in measuring non-observed economic activities to ensure the exhaustiveness of their national accounts.
- Eurostat published *Handbook on the Compilation of Statistics on Illegal Economic Activities in National Accounts and Balance of Payments* (Publications Office of the European Union, 2018) which provides guidance on the concepts and definitions of illegal activities, recommended methodological frameworks for compiling data, and data sources and statistical techniques for recording illegal economic activities.
